Congeſtions are alſo divided into two kinds, from the matter they are occaſioned by: the one are called *ſanguineous*; in theſe the blood is always ready to appear in its own form in an hæmorrhage. The other are ſtiled *bechic*; theſe extend themſelves farther than the ſanguineous, and theſe have their origin from the blood: but when a paſſage is by any means denied to the whole ſubſtance of the blood, its ſerous parts only form the *congeſtions*; and theſe, as they are become either mucidoſeroſe, or ſeroſoſaline, are the occaſion of coryzæ, gravedines, moiſt coughs and aſthmas, cold œdematous, ſcirrhous, and glandulous tumors.

Authors diftinguifh *congeftions* from ftafes fanguinis, by this, that in thefe the quality and progreffive motion of the humors are greatly altered, in the others, as fuch, they are not altered at all.

The figns of *congeftions* are deduced from their effects, and are thefe. In the parts affected there is a diftenfion of the veffels, fo that the very fmall ones, which fcarce appear at another time, are now found turgid, with heavy and tenfive pains, and often, as it were, with a fenfation of pricking; if the *congeftion* be carried farther, there fucceeds to thefe rednefs, and preternatural heat in the part: when upon this there appears an hæmorrhage, all the fymptoms vanifh; but if this difcharge does not happen, there are frequently formed tumors, and running ulcers, with violent pain and inflammation. Thefe are the fymptoms in the affected parts; in the more remote ones, there is a conftriction of the veffels, fo that they appear lefs than natural, and a fenfation of coldnefs in the flefh.

The perfons moft fubject to *congeftions* are thofe of a plethoric habit, and fuch as live fedentary lives, and eat and drink high; and to thefe are to be added, fuch as have been ufed to fome habitual difcharge of blood, whether natural, or by regularly bleeding in the arm at ftated times of the year, and afterwards live wholly without thefe; and fuch as have had iffues, blifters, or old natural ulcers dried up, without ufing the neceffary precautions on fuch occafions. *Junker*'s Confp. Med. p. 90.

Caufes of Congestions. Thefe are principally a plethoric habit of body, and an effort of nature to relieve herfelf from the load, by difcharging part of it at fome proper outlet. To thefe are to be added many external and occafional ones; fuch are a moift and cold air, and fometimes a moift and hot one; a refrigeration of the remoter parts, or of thofe oppofite to fuch as are proper for the *congeftion*.

The effects of *congeftions* are generally ftagnations; and from thefe ftafes and corruptions of the blood and humors, too frequently arife. When *congeftions* are become habitual to a perfon, they very rarely yield to the effects of medicines, even though the material caufe is removed, but often after this renew their fymptoms in fome different way. When *congeftions* are ill treated, efpecially when narcotics are given, or hot medicines, or a warm diet are indulged, they always return the more frequently upon the patient, or bring on a feries of other diforders; and *congeftions* in themfelves are not without danger, when they affect perfons at a certain time of life. Finally, *congeftions* in the breaft are always of more unhappy confequence than thofe of the head and abdomen, becaufe the evacuation of the blood, which is what nature aims at in a *congeftion*, is not to be effected any way happily in the breaft.

Method of treating them. In the time of the paroxyfm, the bowels, which are ufually bound in this cafe, are to be loofened by a gentle emollient clyfter, or by fome of the gentle purges; and the too great expanfion of the blood, and ftricture of the fibres, is to be prevented by abforbents, and nitrous medicines, with the addition of cinnabar, and of the common diaphoretics: to this purpofe powders are to be given three or four times a day, compofed of crabs eyes, nitre, antimonium diaphoreticum, and cinnabar, either native, or that of antimony; and if the pains are violent, a gentle opiate may be added to the powder to be taken at night. To thefe things are to be added the temperate alexipharmics, and the mild and diluent diaphoretics; fuch as tea made of the flowers of lavender, of fage, and the like: and when the blood begins to ftagnate in the place of the *congeftion*, topics may be ufed; fuch as camphorated fpirit of wine, or a cataplafm of caraway feeds, juniper berries, falt, and crumb of bread: and in fome cafes repellents may be fafely ufed; fuch as the vinegar of rofes, and mixtures with nitre, and with faccharum faturni. *Junker*'s Confp. Med. p. 92.

Stuffings *of the breafts*, in infants. See Infant.

STUM, (*Cycl.*) in the wine trade, a term for the unfermented juice of the grape, when it has been feveral times racked off, and feparated from its fediment. The cafks are for this purpofe well matched, or fumigated with brimftone every time, to prevent the liquor from fermenting, as it would otherwife readily do, and become wine.

It is this fume of the fulphur from the match that prevents, in this cafe, all tendency to fermentation, and continues the natural juice of the grape in a fweet ftate, fit to be readily mixed with wines inftead of fugar; for which purpofe it is very much ufed in Holland, and fome other countries, as alfo for giving a new fret, or brifknefs, to decayed wines. So that very large quantities of this *ftum* are annually imported to all parts along with the foreign wines; and after the fame manner a *ftum* is prepared in England from the juice of apples, which ferves the ordinary purpofes of the wine-cooper. In the preferving this liquor in this ftate, we fee the vaft ufe of brimftone, for it could never be done otherwife, than by the matching the cafks. *Shaw*'s Lectures, p. 192. See the article Matching.

Artificial Stum. An artificial muft, or *ftum*, as good as the natural, and as fit for the re-fermenting, fretting, improving, or making of wines, vinegars, and fpirits, may be prepared in the following manner.

Take three pound of fine lump fugar, or fuch as has been well refined from its treacle, melt it in three quarts of water, and add in the boiling of Rhenifh tartar, finely powdered, half an ounce; this diffolves with a remarkable ebullition, and gives a grateful acidity to the liquor; take the veffel from the fire, and fuffer it to cool, and you have an artificial muft, which in all refpects refembles the natural tafte and fweet juice of a white flavourlefs grape, when well purified, and racked off from its fediment, in order to make *ftum*. If this artifical muft be ftummed, that is, well fumigated with burning brimftone, it becomes a perfect *ftum*, and may be made of any flavour, at the difcretion of the artift. *Shaw*'s Lectures, p. 202.

STUPHA, a name given by fome writers to a balneum vaporis.

STUPIO, a name given by fome of the writers in chemiftry to tin. See Tin.

STURDY, in cattle, a kind of diftemper, otherwife called the *turning-evil*. See Turning-*evil*.

STURIO, the *fturgeon*, a very well known, large, and fine-tafted fifh, caught in many places, and fometimes in the river Thames, being one of thofe fifhes called *anadromi* by authors, which fpend a part of their time in the fea, and a part in rivers.

It never goes into the fea to any great diftance, and never is caught there of any very great fize. The fea ferves for its production, but it is only in large rivers that it grows to its ufual fize. *Ray*'s Ichthyogr. p. 248.

STURNUS, the *ftarling*, a bird very well known, and of the thrufh, or turdus kind.

There is, befide the common fpecies, a very beautiful one, defcribed by Bontius under the name of the *Indian ftarling*, or *fturnus Indicus*. This is of the fize and fhape of our common *ftarling*, but is variegated with a deep blue, a lead colour, and a pale grey, and has on its head a very beautiful yellow creft. It learns to imitate the human voice, and talks much better than the parrot, but is troublefome in being over noify. *Ray*'s Ornitholog. p. 145.

Linnæus makes the *fturnus* a diftinct genus of birds, of the order of the *pafferes*; the diftinguifhing characters of which are, that the tongue is membranaceous, fharp, and edged with a rim, or margin; the beak is of a fomewhat cylindric form, and is pointed and crooked. *Linnæi* Syftem. Naturæ, p. 49.

STYE, or Stithe, the Englifh name for a diforder on the eyelids, called by the phyficians *hordeolum*, and by fome *crithe*, *chalazium*, or *grando*.

It is a fmall encyfted tumor, ufually of about the bignefs of a barley-corn, which fometimes degenerates into matter, and occafions great pain and uneafinefs.

The tendernefs of the organ of fight makes it neceffary to be careful about thefe tumors, which, if fituated in any other part of the body, would hardly deferve much attention. Some authors commend cataplafms, and the like applications, to thefe, but the eye is often hurt by thofe applications; and it is obferved befides, that thefe tubercles feldom give way to topical applications of any kind.

When they are fmall, it is beft to let them take their own courfe; but if fo large as to occafion deformity, or danger of hurting the fight, the way to extirpate them, is to make a longitudinal incifion on the part, and carefully take them out whole; or if it cannot be thus got out clean, it muft be cut out, as far as may be, with fciffors, and dreffed with Ægyptian ointment, and a little red precipitate, or touched at times with the common cauftic, till eaten thoroughly away, and then the wound dreffed and healed in the common manner.

This is the method by which the flat and broad-bottomed tumors of this kind are to be extirpated; and in this great care muft be taken that none of the fharp applications touch the eye, as they might injure the fight. It is common, however, with thefe tumors to hang by a fort of fmall root, and then they are much more eafily managed, there being no more neceffary than the cutting them clofe off with a pair of fciffors, or the tying them firmly round with a piece of filk, or horfe-hair. They are fometimes, if taken in time, difperfed by rubbing them with fafting fpittle, or with applying the pulp of a roafted apple mixed with fome faffron and camphor. *Heifter*'s Surgery, p. 365.

STYGIA *aqua*, a term ufed fometimes to exprefs aqua regia; fometimes for the other ftrong acid fpirits.

STYLE, among botanifts. See Pistil.

STYLOBATON, or Stylobata, in architecture, the fame with the pedeftal of a column. It is fometimes taken for the trunk of the pedeftal, between the cornice and the bafe, and then called *truncus*. It is alfo called by the name of *abacus*.

STYLOCERATOIDES, in anatomy, a name given by Riolanus, and fome others, to a mufcle, more generally known by the name of *ftylohyoidæus*. See the next article.

STYLOHYOIDÆUS, a small fleshy muscle, lying obliquely between the apophysis styloides, and os hyoides.

It is fixed laterally by one extremity to the root, or basis of the apophysis styloides, and by the other to the os hyoides, at the place where the basis and cornu unite, and likewise to the cornu itself, from whence it has been called *stylo-cerato-hyoidæus.* The fleshy fibres of this extremity are often parted, and inclose the middle tendon of the digastricus. *Winslow's* Anatomy, p. 255.

STYLOHYOIDÆUS *novus*, a name given by Santorini to a small muscle of the os hyoides, called by Albinus *stylohyoidæus alter*, and by Douglass *stylochondrohyoidæus.* See the articles MOUTH and Os *hyoides.*

STYMMATA, a word used by some authors to express the stiff ointments. The antients used the word both for their more solid and stiff ointments, and for the ingredients which gave those ointments that consistence: they also called by the same name the several sweet ingredients which they put into their ointments, to give them a fragrancy, and preserve them from corruption; such were the powders of spikenard, mint, amomum, and the several spices.

STYMPHALIA, Στυμφαλια, in antiquity, a festival at Stymphalus in Arcadia, in honour of Diana, called from that place *Stymphalia. Potter*, Archæol. Græc. Tom. I. p. 431.

STYMPHALIDES *aves*, in fabulous antiquity, birds of an extraordinary size, which in their flight are said to obscure the sun. They fed only on human flesh; but Hercules, by the help of Minerva, drove them out of Arcadia by the noise of cymbals. *Danet.* in voc.

STYPTIC (*Cycl.*)—STYPTIC *powder of Helvetius*, in pharmacy, a composition of alum and dragon's blood. In the Edinburgh dispensatory, two parts of alum are directed to be made into powder with one of the dragon's blood: others use equal parts of both. See Med. Eff. Edinb. Vol. 4. Art. 7.

This medicine is said to be extremely serviceable in uterine hæmorrhages, either to correct the too frequent return of the menses, or their too great abundance; also to stop the flooding, to which women with child are subject, and to moderate the flow of the lochia. It has also been found to have surprising good effects in the fluor albus.

In violent bleedings it may be given in the quantity of half a drachm every half hour, and it seldom fails of stopping the bleeding before three drachms, or half an ounce has been taken. See Medic. Eff. ibid.

Heister also, in his Compendium Medicinæ Practicæ, p. 143, recommends this powder, or alum alone, with a decoction of lin-seed, from Helvetius Traité des pertes de sang.

Eaton's STYPTIC, a medicine famous for curing fresh wounds in a very small time, and immediately stopping their bleeding.

The method of curing fresh wounds in a few days without suppuration, where neither nerves, large vessels, bones, nor any of the viscera are concerned, has been a practice long ago used.

Purman, a famous surgeon of Breslaw, in his Chirurgia Curiosa, tells us of a mountebank who gave himself thirteen wounds by incision in the upper part of his left arm, and applying his nostrum with a common roller, the wounds were all well in two days: and both this author, and Blegny, mention what they call a *martial styptic*, which cures wounds in two days, especially if the patient take also a few drops of it inwardly.

The French were a long time very fond of a *styptic* ball made of filings of iron and tartar, mixed to a consistence with French brandy, which was afterwards published by Helvetius, and from him has been generally known by the name of *Helvetius's styptic.* This was extolled with us as one of the greatest medicines in the world for the cure of wounds, bruises, and external injuries of all sorts: but the author never said so much about it; he only modestly introduced it into the world as an useful thing for a first dressing of fresh wounds with people who lived too far off for the immediate assistance of a surgeon: and he mentions several cases, in which it ought not to be used. In fine, he published it as a good medicine under proper restrictions; but we made it an universal one. The only universal remedy of this kind, that we have had recommended by the author as such, is the famous *styptic* of Dr. Eaton, which the inventor says is good to stop all manner of bleeding both without and within, without any manner of exception.

Sir Richard Blackmore, soon after the publication of this great secret, wrote a treatise on consumptions, in which he highly extols this *styptic* of Dr. Eaton, declaring positively, that it will be of more service to the world than all the discoveries that had been made before it. On this Dr. Sprengel, who had before examined *Eaton's styptic*, and judged it to be no other than that of Helvetius; which, after having been tried and discarded in France, Germany, and Holland, had been set on foot as an universal medicine here, thought it worthy a more strict and public examination, and ordering an apothecary of credit to prepare him some of Helvetius's *styptic* in the common way, he produced before a judicious audience a bottle of that, and another of *Eaton's styptic*; and giving them both the same trial, they both answered in the same manner, and proved, beyond all possibility of doubt, that they were in effect the same medicine.

The same trials were made by several other chemists, physicians, and apothecaries; and the event proving the same in all, it appeared wonderful that a man, who had a mind to sell a known medicine under the notion of a secret, should not have had the caution to alter or disguise it either in taste, smell, or colour; which he might very easily have done, without at all impairing its virtues as a medicine.

The usual method of trying a *styptic* is upon the crural artery of a dog cut open for that purpose. In this manner the *styptic* of Helvetius and Eaton were both tried, and both answered very well; and plain French brandy being also tried, had the same success; whence it appeared, that there was no very great virtue in either, more than the heat of the spirit, which forcibly constringed the fibres: and when we consider the smallness of the crural artery in a dog, we shall not wonder that a trifle stops the bleeding of it, since, with a bit of dry lint, or even with no application at all, the bleeding will stop of itself, without any hurt to the animal. By this, and by the common experiments made upon this *styptic* on other occasions, its external virtues appear to be very trifling. Internally, however, it is a much worse medicine. It is too often given in natural hæmorrhages; and in all these cases, as there is a stimulation and feverish disposition, which gives occasion to the bleeding, it is certain that any thing, of the nature of brandy and a chalybeate, must add to it, instead of curing it. Upon the whole, the virtues of these *styptics* externally are too trifling to be trusted to; and internally too precarious to meddle with, without the greatest caution. Philos. Trans. N° 383. p. 110.

STYRAX (*Cycl.*)—STYRAX, the *storax-tree*, in botany, the name of a genus of trees, the characters of which are these. The flower consists of one leaf, and is of the funnel-fashioned kind, and divided into many segments at the edges. The pistil arises from the cup, and is fixed, in the manner of a nail, into the hinder part of the flower: this finally becomes a roundish, or fleshy fruit, containing one or two kernels, in which are soft seeds.

There is only one known species of this tree, which is the common, or quince-leaved *storax-tree. Tourn.* Inst. p. 598. See the article STORAX.

SUBARMALE, among the Romans, a coarse and thick kind of cassock worn by the soldiers under their arms, in order to keep them from being hurt with their weight. *Pitisc.* Lex. Ant. in voc.

SUBBUTEO, in zoology, the name of a bird of the hawk kind, called in English the *ringtail*; the male of which is called the *hen-harrier.* Some authors give it the name of *pygargus accipiter. Ray's* Ornithol. p. 40. See the articles RINGTAIL and HEN-HARRIER.

SUBCLAVIUS, a small oblong muscle, lying between the clavicle and first rib. It is fixed by one end in all the middle lower portion of the clavicle, at the distance of about an inch from each extremity; and by the other in the cartilage, and a small part of the bone of the first rib. It seems likewise to adhere to the extremity of the clavicle, next the sternum, by a kind of broad thin ligament. *Winslow's* Anatomy, p. 177.

SUBCOSTALES. These muscles are fleshy planes of different breadths, and very thin, situated more or less obliquely on the inside of the ribs near their bony angles, and running in the same direction with the external intercostals. They are fixed by other extremities in the ribs, the inferior extremity being always at a greater distance from the vertebræ than the superior, and several ribs lying between the two insertions. These muscles are more sensible in the lower ribs than in the upper, and they adhere closely to the ribs that lie between their insertions. *Winslow's* Anatomy, p. 233.

SUBDUPLICATE *ratio* of any two quantities, is the ratio of their square roots. See RATIO.

SUBER, the *cork-tree*, in botany, the name of a genus of trees, the characters of which are these. The fruit and flowers are the same with those of the ilex, but the bark of the tree is thick, fungous, and light.

There are two species of this tree. 1. The ever-green broad-leaved *cork-tree.* 2. The *cork-tree* with narrow, and not serrated leaves. *Tourn.* Inst. p. 584.

SUBETH, the word used by the Arabian writers to express a carus.

SUBETH *sahala*, a term used by the Arabian writers to express a coma vigil.

SUBFRONTALIS *sutura*, a name given by some anatomical writers to the suture, by which the os frontis is connected with the bones of the superior jaw.

SUBJECT (*Cycl.*)—SUBJECT, in the manege. To keep a horse *subject*, is an expression relating to volts; signifying, to keep the croupe of the horse in the round, so that it may not slip out; that he may not traverse; and that he may work

work in the manege, croupe in, marking his equal times, without lofing his ground.

SUBJECT, in mufic. See SOGGETTO.

SUBJECTION, *fubjectio*, in rhetoric, is ufed for a brief anfwer to a preceding interrogation: thus Cicero, *Quid ergo? audaciſſimus ego ex omnibus? minimè.* *Voff.* Rhet. lib. 5. p. 416.

SUBINTRANTES *febres*, a term ufed by fome medical writers to exprefs thofe fevers in which one fit begins before the other is perfectly worn off.

SUBITO, in the Italian mufic, is ufed to fignify that a thing is to be performed quickly and haftily: thus we meet with *volti fubito*, turn over the leaf quickly.

SUBLIMABLE *bodies*, a term ufed by fome of our chemical writers to exprefs fuch fubftances as are capable of *fublimation* in a dry form.

They fay that only thofe things are *fublimable*, which contain a dry exhalable matter in their original conftruction; and among thefe they find a great variety, which require various methods and means to execute that effect. Among the minerals, fulphur, antimony, and orpiment, are named as the principal among *fublimable* bodies: thefe are of a very lax compage, or ftructure, and are eafily raifed by fire in fmall particles, which concrete again on being ftopt from flying off by the cover of the veffel; while, on the contrary, iron, filver, and the other metals, being of a clofer ftructure, remain fixed in the greateft heat, and never afcend, unlefs mixed with fome volatile fubftance that is itfelf capable of rifing, and of taking up fome of them with it.

Thus copper and iron will be raifed in *fublimation* by means of fal armoniac mixed with them; and even gold itfelf is faid to be fubject to the fame law, Mr. Boyle affuring us, that he had a fecret method of preparing a certain faline fubftance, by means of a very fmall admixture of which, the gold would be made to rife in *fublimation*, and form fine purple cryftals.

Fire is the great agent in *fublimation*; and according as thefe bodies are more or lefs denfe and compact, this is to be made more or lefs ftrong, and continued a longer or a fhorter time. Very often the internal heat alone, occafioned in vegetable or animal fubftances by fermentation, is fufficient to *fublime* certain of their principles, as is evident in Wedelius's inftance of a ball of woad, or glaftum.

Many fubftances of a loofer texture are to be *fublimed* alone, and many others are to have other things mixed with them, as before obferved, in order to make them fubject to this operation of the fire. The admixtures, which are to make bodies *fublimable* which are not fo in themfelves, are to be of various kinds, according to the nature of the body to be *fublimed*; and the attempt of this procefs upon any particular body is never to be given over on the firft effay, but the whole round of thofe things, which render *unfublimable* bodies *fublimable*, are to be tried firft, that what one does not effect, another may have its chance of doing.

Among thefe bodies, ufed as mixtures in *fublimation*, fome act by rendering the body more eafily fufible, and difuniting thofe particles more readily which the fire is expected to carry up; others act only by preventing the cohefions of the particles of the fubftance to be *fublimed*, which heat would otherwife occafion; and finally, others by entering the body of the fixed fubftance they are mixed with, and giving wings, as it were, to its fubtle particles, fo that they may afcend with its eafily *fublimable* matter, and join with it in the formation of one mixed fubftance in the top of the veffel, by partaking of the nature of both. Others act potentially in the fame way, but by different means, themfelves not being capable of *fublimation*, but acting on the fubftance to be *fublimed*, by enervating, weakening, or abforbing thofe fubftances, or parts of the mixed body, which would have otherwife prevented the afcent of the reft; and finally, fome act as diffolvents only, and by that means render things eafy of *fublimation*, which would have been very difficultly fo, while their parts were in a more ftrict continuity. The ufe of this management of *fublimable* bodies is to prepare the flowers, the fulphurs, or the volatile falts of thofe bodies, pure and feparate from their terreftrial fæces, from phlegm, from impure oils, and from acids; and the mixing together the *fublimable* bodies of two or more kinds into one fubftance, proper for the ufes of medicine, painting, *&c.* as in the combination of mercury with fulphur into cinnabar; a noble medicine, and a very valuable paint; or with corrofive falts into the common drugs, called, by way of pre-eminence to all others, *fublimate*. *Hoffman's* Acta Laborat. Chem.

SUBLIMATE (*Cycl.*)—*Corrofive* SUBLIMATE. In making *fublimate*, the quickfilver is extinguifhed by trituration in calcined vitriol. But Monfieur Lemery obferves, that bole armeniac and potters clay are cheaper, and extinguifh the mercury fooner.

It has been faid, that to try whether *fublimate* has been fophifticated with arfenic or not, it was to be rubbed with falt, or oil of tartar; and that if fophifticated, it would turn black. But Mr. Lemery agrees with Barchufen and Boulduc, that this is no trial; for the falt of tartar has the fame effect on the good and the bad *fublimate*. See Mem. de l'Acad. des Scien. 1734.

Dr. Kirften affirms that *fublimate*, rightly prepared, becomes firft faffron coloured, and then red, when oil of tartar is dropped on it: whereas, if it is adulterated with arfenic, it becomes firft near the colour of brimftone, then red, afterwards afh coloured, and laftly black. He is pofitive in this, notwithftanding what Barchufen and Boulduc have faid to the contrary. Commerc. Norimb. 1738. Hebd. 12. §. 2.

An anonymous chemift affirms, that *fublimate* prepared with arfenic becomes at laft white, inftead of black, when touched with oil of tartar. He fays, that in the *fublimation* of fweet mercury, where the *corrofive fublimate* has been adulterated, the upper part is of an orange colour, and a white earth remains in the bottom, and the belly of the glafs becomes dark coloured, or fmoaky; whereas, when the corrofive mercury is genuine, the upper part is white, the powder in the bottom is red, and the middle is not fmoaky coloured. But the fweet mercury, prepared with genuine or adulterated corrofive, appears on every trial the fame.

Dr. Kramer relates the hiftory of a lad who fwallowed half an ounce of *corrofive fublimate*; foon after which his mouth and ftomach were fo eroded, that he voided large quantities of blood, both upwards and downwards, with violent gripes, coldnefs of the extremities, ftartings of the tendons, and racking pain. A vomit was foon given; notwithftanding which the fymptoms continuing, Dr. Kramer ordered mild drink, with large quantities of oil of tartar *per deliquium* in it, by which the fymptoms foon were mitigated, and the cure was compleated by giving theriaca andromachi, with terra figillata, and putting him into a warm bath. Commerc. Norimb.

Blue SUBLIMATE, a preparation of mercury with fome other ingredients, yielding a fine blue for painting. The method of making it is this: take quickfilver two parts, flower of brimftone three parts, fal ammoniac eight parts; grind thefe upon a porphyry, and with the quickfilver put them into a long-necked glafs veffel luted at bottom; place it in a fand-heat, and when the moifture is afcended, you will have a fine *blue fublimate* for painting. *Neri's* Art of Glafs, p. 164.

SUBLIMIS, in anatomy, a name given by Albinus, Hunaud, and others, to the mufcle of the wrift, called by others the *perforatus*. See the article PERFORATUS.

Thefe authors call the perforans the *profundus*. See the article PERFORANS, *Cycl.*

SUBLINGUALIA, a term ufed by fome authors to exprefs fuch medicines as were intended to be laid under the tongue, and gradually diffolving there.

Thefe have been principally intended either to cure coughs, or give a fweet fcent to the breath.

SUB-MARSHAL, an officer in the Marfhalfea, who is deputy to the chief marfhal of the king's houfe, commonly called the *knight marfhal*, and hath the cuftody of the prifoners there. He is otherwife termed *under marfhal*. Crompt. Jurif. 104. *Blount*, *Cowel.*

SUBMARINE *navigation*. See the article *Submarine* NAVIGATION.

SUBMERSION, *fubmerfio*. See DROWNING.

SUBMISSIO, a word ufed by medical writers to exprefs a remiffion.

Sometimes it imports the fame as *fyftole* with refpect to the arteries, that is, their contraction.

SUBPRINCIPALIS, in fome Latin writers of mufic, is ufed for the note or chord called by the Greeks παρυπατη, *parhypate*.

SUBPURGATION, *fubpurgatio*, a word ufed by fome writers to exprefs a gentle purgation.

SUBROTUND *leaf*, among botanifts. See LEAF.

SUBSCAPULARIS, (*Cycl.*) a mufcle of the fame breadth and length with the fcapula, of which it occupies all the inner or concave fide; and having its name from its fituation.

It is thick, and made up of feveral penniform portions, nearly in the fame manner with the deltoides. It is fixed in the internal labium of the whole bafis, and in almoft the whole internal furface of the fcapula; its flefhy portions lying in the intervals between the bony lines, when thefe are formed. Near the neck they leave the bone, and form a very broad tendon, which is inferted in the furface of the fmall tuberofity of the head of the os humeri, clofe by the bony channel. The lower edge of this tendon probably fends off the ligamentary frænum, mentioned in the defcriptions of the latiffimus dorfi, teres major, and coracobrachialis. This mufcle covers immediately the ferratus major, being in a manner inclofed between it and the fcapula: the upper edge of its tendon is joined to the lower edge of that of the fupra fpinatus, except at the upper part of the bony channel, where they give paffage to one tendon of the biceps. It likewife adheres to the capfular ligament. The tendons of the fupra fpinatus, infra fpinatus, teres minor, and *fubfcapularis*, being all joined by their edges, form a fort of cap, which covers the upper part of the head of the os humeri. *Winflow's* Anatomy, p. 184.

SUBSISTENCE, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay, becaufe their clothes, accoutrements, tents, bread, &c. are to be paid; it is likewife the money paid the officers upon accompt, till their accompts be made up, which is generally once a year, and then they are paid their arrears.

SUBTERRANEAN (*Cycl.*)—SUBTERRANEAN *fires*. Among the many places where thefe *fires* are found, England is not wholly without them; though with us they appear only in the coal countries, and plainly feed on nothing but the upper ftratum of the coal, called by the miners *day coal*, unlefs where they have by accidents been kindled by actual fires at great depths, or fired downward, by being pent in for room. See VOLCANO.

They have, in many places, been known to burft out fpontaneoufly from the furface, and make their courfe both ways from the place along the ftratum. There is no actual native fulphur found there, but there are plenty of the marcafites, to which the *fire* is probably originally owing; as we know that thefe ftones, piled up in a heap in the air, will often take fire of themfelves.

If at any time a fmall quantity of melted fulphur fhould be found in the earth, it is not to be fuppofed to be native there; for the *fire* acting on the other marcafites it meets with, may very well melt and feparate the fulphur from them, as is done at Goffelaer, and in fome other places, where the fulphur we commonly ufe is made in that manner by art. It has been faid, that crude fal armoniac is found in the earth in thefe places; but it is only met with at the mouths of the *fire*. Where the fmoak afcends in thefe places, there continually arife vaft quantities of the vapours of fulphur, as well as fal armoniac; and crufts of the flowers of fulphur, and of fublimed fal armoniac, are found together around thefe openings. The brimftone generally arifes firft, and forms a cruft, under which there is a cruft of fal armoniac. It is remarkable, that in the places where thefe *fires* have burnt, there are often found cavities in the rocks, containing a white milky liquor of a ftyptic tafte: this is a fort of liquid alum, and yields generally about one half of that falt.

The fal armoniac is found in confiderable quantities in fome of thefe places, yet its origin is not eafily accounted for on the common principles; for neither nitre, nor common falt, are found in the earth thereabouts. The fprings alfo, which arife in the neighbourhood of the places where the *fire* is, have been diligently examined, and no fufpicion of the leaft admixture of fal armoniac appears in them. The water that runs through the ftrata of coal in all thefe countries is vitriolic, and turns black with a decoction of galls. There needs no more than burning pit coal to produce fal armoniac; for it has been found produced in brick-kilns, where nothing but coals and clay have been laid together: and here it muft be afcribed to the coal alone, no one ever having found it in clay. Phil. Tranf. N° 130. See FIRE.

We have an account, in the Philofophical Tranfactions, of a *fubterranean* town found at Portici, near Naples, in which many antique ftatues, paintings, and other curiofities, have been found.

This *fubterranean* town is probably the antient city of Herculaneum, which was fwallowed up by an earthquake. See Phil. Tranf. N° 458. fect. 4, 5, and 6.

It is remarkable, that fome of the antique paintings found there are as frefh and perfect, as if lately painted. Ibid. fect. 6.

SUBTRACTION. See the article SUBSTRACTION, *Cycl.*

SUBVERSIO *ftomachi*, a term ufed by fome authors to exprefs a violent vomiting, when what fhould pafs through the inteftines is voided conftantly by the mouth.

SUBULARE *folium*, among botanifts. See LEAF.

SUBULATED *leaf*, among botanifts. See LEAF.

SUBULO, a term ufed by Pliny for deer two years old. See the article FERULÆ.

SUBULO, in natural hiftory, a word ufed by the antients to exprefs a deer, or ftag, at that time of its life when the horns firft begin to appear.

Others have underftood it as the name of the oryx, whofe horn was narrow at the fummit, and thence gradually larger toward the bafe, fo that it refembled the figure of the fubula. This is the fabulous creature called the *unicorn*, and defcribed as a nimble and terrible animal. But it is certain that no fuch animal ever exifted, as is called by this name, and thus defcribed: the only one-horned animal in the world is the rhinoceros, and this is an unwieldy heavy animal, not at all refembling the characters or figures we have of the *fubulo*, or oryx.

It is to be obferved, that the *fubula* of the moft antient writers was an inftrument of iron, fharp at the point, ufed in the ftone-quarries to break way through large maffes.

SUCCENTURIATI (*Cycl.*)—It is the opinion of Dr. Kerkring, and of many fince his time, that thefe are cafes in which there is elaborated a bilious juice, which afterwards, either by the emulgent vein, or, as often is the cafe, immediately paffes to the cava, and being thence conveyed to the heart, raifes there that effervefcence, which Sylvius contends to be excited in that part by the mixture of a faltifh liquor with an acid: for although experience contradicts the conveyance of the juice out of the liver through the cava, yet that effervefcence in the heart, upon which the whole fyftem of Sylvius is grounded, may ftill hold, if this opinion about the ufe of the *fuccenturiati* be true. As there needs but very little leaven to ferment a large mafs, which is in a proper ftate and condition to be fermented, a very minute quantity of falt of tartar, mixed with a very large portion of oil of vitriol, will occafion not only a very confiderable, but a very lafting fermentation; though a very confiderable quantity of the latter, poured on a quantity of the former, caufes but a languid and fhort effervefcence. This account of an opinion, though not now received, may be worthy the confideration of thofe who remember how cautioufly both fides of a queftion ought to be heard, before any thing is determined in regard to it. *Kerkring*, Spicileg. Anat.

SUCCIFERA *vafa*, in natural hiftory, a name given by thofe who have written of the anatomy of plants, to thofe veffels which contain the juices, by way of diftinction from thofe which only give paffage to the air, and are called *tracheæ*. Lewenhoek tells us, that the microfcope difcovers the *fucciferous* veffels of plants to be, in all refpects, analogous to thofe of animals, and that they are of two kinds, veins and arteries: the latter receiving the juices from the root, and carrying them all over the plant; and the others receiving the juice from their extremities, and carrying it back again to the root, where it is again delivered to the arteries.

SUCCINUM, *amber* (*Cycl.*)—The origin of *amber* has been much difputed among the naturalifts, and many erroneous, and fome even abfurd, conjectures made about it. There feems however, from experiment and a clofer obfervation, to be no doubt but that it is wholly of mineral origin, and is a bitumen which was once liquid, and of the naphtha, or petroleum kind, hardened and brought into its prefent ftate by a mineral acid, of the nature of fpirit of fulphur, or oil of vitriol; both thefe fubftances abounding in the earth, and an artificial mixture of them producing a body much refembling *amber*, and affording all its principles on a chemical analyfis.

Flies, and other fmall infects, found bedded in *amber*, have by fome been fuppofed mere *lufus naturæ*, and never to have been real animals; but this needs only the eye to difcover its abfurdity: and with others, who allow them to be real, they are ufed as proofs that *amber* is of vegetable origin, and was once foft and fluid. That they do prove the laft is certain, but by no means the firft. To judge properly of this, we fhould confider the true ftate of the cafe, which is this: that more than a thoufand pieces of *amber* are found without infects, for one that has any; and that moft of the pieces which have them, have not been dug out of the earth, but found on the fea fhores. The fides of hills we well know are continually trickling down the liquid bitumens; and there is no abfurdity in fuppofing, that fmall quantities of this might, in its paffage, be detained in little cavities of rocks, &c. and there fuffer leifurely its change into *amber*, from the matter of its natural acid being near. And it can be no wonder that flies, &c. fhould be drowned in fuch a mafs of matter, which being afterwards hardened, might be found on the furface of the earth, or wafhed down to the fea, in the form of common *amber*. Nor is there any thing impoffible in the maffes, thus formed on the furface, being afterwards buried in the earth, by the various changes we know the furface of the earth at times is fubject to.

Befide the places whence *amber* is ufually brought, which are Pruffia, Pomerania, &c. we have it on our own fhores, and even in our clay-pits; the pits dug for tile clay, between Tyburn and Kenfington Gravel-pits, have afforded many fpecimens; and that behind St. George's Hofpital, at Hydepark Corner, has afforded fine fpecimens, one of which has been wrought into a beautiful cane-head of three inches long. *Hill's* Hift. of Foff. p. 409.

If the people, who collect *amber* on the fhores of the Baltic, were more curious and particular in their obfervations of the maffes they find, we fhould doubtlefs have much more lights into its true hiftory and nature. There is no queftion, but that fome pieces of it are toffed up there fo imperfectly formed, that the procefs of nature may be feen in their different ftages. Pieces have been fometimes found fo foft, as to receive the impreffion of a feal: thefe are always not only perfect *amber* in other refpects, but they are obferved to have a fmell ftronger than the common *amber* has. Thefe pieces fometimes harden immediately, on being expofed to the air, but fometimes they retain this foftnefs many months. We have an account of fuch a piece in the Philofophical Tranfactions, which had retained this foftnefs a whole year, in which time it had lain among other pieces of *amber*; and of another mafs very foft on one fide, and hard on the other, and containing in the foft part a fly buried. Phil. Tranf. N° 57.

This foffil has been of great repute in the world from the very earlieft times we have any knowledge of, many years before

before Chriſt it was in eſteem as a medicine; and Plato, Ariſtotle, and Herodotus, and among the poets Æſchylus, and others, have commended its virtues. In the times of the Romans it became in high eſteem as a gem; and in the luxurious reign of Nero immenſe quantities of it were brought to Rome, and uſed for ornamenting works of various kinds. Long after this Theodoric, king of the Goths, ſhewed a high eſteem for it. However well known, and however highly eſteemed this ſubſtance was in theſe ages, its nature and origin yet remained unknown through a long ſeries of time, and various conjectures were made about it in the different places where people were poſſeſſed of it among their gems; ſome ſuppoſed it the product of Africa, others of Aſia, and others of America; and the gardens of the Heſperides, Ægypt, Æthiopia, and Numidia, were ſuppoſed, in the firſt mentioned part of the world, to give it birth. Thoſe who made it the produce of Aſia, gave Arabia, and ſome parts of the Eaſt-Indies, as the places of its production; and thoſe who ſuppoſed it brought from Europe, gave Italy, the river Eridanus, and the borders of the Adriatic, as the only parts whence it came: but the Romans, when they ſpread the terror of their arms through Germany, found it on the ſhores of the German ocean and the Baltic, and Spain, and afterwards Britain, were added to the liſt of places where it was found.

The antients, who had leſs traffic, and leſs knowledge of the world than we have, are the more pardonable in allotting ſo great a number of places, and many of them falſe ones, for the production of *amber*, and for not diſcovering the true place where it has been at all times found in the greateſt plenty, and whence moſt parts of the world have long been, and are to this day ſupplied; but the moderns are much more unpardonable, who in their accounts give us Aſia, Africa, and America, as the places where *amber* is found, as if it were to be had no where elſe; and ſome of them diſtinguiſh the finer pieces under the name of *Oriental amber*.

The generality of theſe falſe accounts of *amber*, have been owing to the ignorance of the perſons who have taken upon them to give the hiſtory of it: they have, in general, taken upon hearſay what they have related, or borrowed it from books they were not able to underſtand. Thus we find the many places in Aſia and Africa celebrated for producing large ſtores of *amber*, are taken upon credit from the old authors, who have mentioned ambra as being found there. Theſe copiers not diſtinguiſhing, that ambra in theſe places is not given as the name of *ſuccinum*, or *amber*, but as that of the rich perfume called *ambergris*, which is found there, though the real *amber* never was.

The name of *Oriental amber*, ſo common with ſome, ſeems to have been owing alſo to a miſtake, but of another kind; the gum copal, brought from the Eaſt-Indies, is very like *amber*, and ſome of the fantaſtic writers in chemiſtry have called this by the forced name of *Oriental amber*. Hence thoſe who read their works, without perfectly underſtanding them, have ſuppoſed that *amber* was common in the Eaſt-Indies; and as all the gums of that part of the world are ſuperior to thoſe of other places, they began to call all the fine pieces of this foſſil by the pompous name of *Oriental amber*.

We are not to limit the operations of nature ſo far, as to ſay that ſhe does not, or cannot produce *amber* in Aſia, Africa, or America; but it is certain, that we have no authentic account of its ever having been found in any of thoſe regions, and there is the greateſt reaſon in the world to believe that it is peculiar to Europe. This we are very well aſſured of, that the Chineſe, who are as cunning a people as any in the world, expend annually with us vaſt ſums of money in buying European *amber*, and have done ſo at all times ſince we have trafficked with them; and it is by no means to be ſuppoſed that they would purchaſe it of us, if they had it nearer home. All the intelligent perſons, who have reſided in the Eaſt-Indies, ſay, that they never ſaw or heard of *amber* being found there. And, upon the whole, it ſeems very rational to conclude, that *Oriental amber* never exiſted, otherwiſe than in the error beforementioned, of calling copal by that name.

Europe ſeems the only region of the world where *amber* is produced: it ſeems alſo to be produced almoſt all over Europe, but not in equal plenty, nor perfection; the German dominions, and the country about the Baltic, claim the prerogative above all other places. Hartman, who has given the abovementioned account of the errors of the antients, &c. in regard to the places of its origin, has been too free in cenſuring the moderns for giving it to ſome parts even of Europe: he ſcruples to believe that Italy, Spain, and even England, produce *amber*; but in this he errs: he ſuppoſes that jet, which is called by ſome *black amber*, being found in theſe places, has impoſed upon the authors of theſe accounts, and made them ſay *amber* was found there; but nothing is more certain, than that *amber*, and that of the fineſt kind in the world, is found in England, at leaſt, if not in the other places where he doubts of its production. *Amber* is at this time thrown on the ſhores of Yorkſhire, and many other places, and found at great depths under the earth, in ſtrata of clay, as well about London, as in more inland places; and if we mention Dr. Woodward, and the other authors, who have themſelves taken it up, we ſhall have no room to doubt its being real *amber*, not jet, as Hartman ſuppoſes.

Poland, Sileſia, and Bohemia, are famous for the *amber* dug up there at this time. Germany affords great quantities of *amber*, as well dug up from the bowels of the earth, as toſſed about on the ſhores of the ſea and rivers there. Saxony, Miſnia, and Sweden, and many other places in this tract of Europe, abound with it. Denmark has afforded, at different times, ſeveral quantities of foſſile *amber*; and the ſhores of the Baltic abound with it. But the countries lying on the Baltic afford it in greateſt abundance of all; and of theſe the moſt plentiful country is Pruſſia, and the next is Pomerania. Pruſſia was, as early as the times of Theodoric the Goth, famous for *amber*; for this ſubſtance coming into great repute with this prince, ſome natives of Pruſſia, who were about his court, offered their ſervice to go to their own country, where that ſubſtance, they ſaid, was produced, and bring back great ſtores of it. The offer was accepted, the journey ſucceſsful, and from this time Pruſſia had the honour to be called *The Country of Amber*, inſtead of Italy, which had before undeſervedly that title.

The *amber* of Pruſſia is not only found on the ſea coaſts, but in digging; and though that of Pomerania is generally brought from the ſhores, yet people, who dig on different occaſions in the very heart of the country, at times find *amber*. Philoſ. Tranſ. Nº 248. p. 5, ſeq.

In Pruſſia the cliffs are very high and abrupt, and are all of naked earth, except a few rocks; the ſhore is very even, and the ſea ſhallow for a long way; after this there is a conſiderable depth for ſome furlongs, and behind this the ſhallows riſe again, and continue a great way. The ſtormy ſeas, and high tides, waſhing againſt theſe cliffs, break down vaſt maſſes of them from time to time; in the matter of theſe maſſes of earth lie great quantities of *amber*; this mixture falling upon the flat ſhore, is daily waſhed by the waves, and the earth waſhed, and broken to pieces in a little time, and carried back by the waves into the ſea; while the lumps of *amber*, being too hard to break, and too large to be carried away ſo eaſily as the diſunited particles of earth are, remain naked on the ſhore, or in the ſhallower water. If they are any of them waſhed away, they are only carried into the firſt deep water, and by its riſe and fall in the tides they are thrown up, either on one ſide or the other, and lodged on the ſhallows, from whence the people, employed to gather them, eaſily obtain them.

The whole country about theſe cliffs abounds in *amber*, but it is impoſſible to get at it by digging, becauſe of the nature of the ſoil, which is boggy, and full of water, riſing in ſome places up into ſprings, and in others making the ground ſo ſoft, that there are a ſort of bogs and quickſands, which ſwallow up cattle, and ſometimes men and their horſes. A little higher up in the country, where digging is practicable, the earth is found of the ſame nature as in the face of the cliffs, and abounds with minerals of various kinds. The pyritæ, and vitriols of many ſorts, are found there, and ſtrata of a ſort of black earth, with white veins, in great abundance. Under theſe ſtrata there is found a great quantity of a cortical ſubſtance, reſembling the barks of trees, among, or under which the *amber* is uſually found. The whole face of the country is very barren; in this part tracks of ſand often cover vaſt ſpaces, and ſometimes a few weeds of the hardieſt kinds appear; ſometimes a buſh, but rarely, and ſcarce any ſuch thing as a tree is to be ſeen. The *amber* in theſe places, when dug up, is uſually foul, and covered with a rough opake coat, which muſt be taken off, or broke through, in order to the ſeeing its beauty; but that on the ſhores is uſually found clear and fine, this outer cruſt having been worn off by the waſhing of the waves. This *amber* on the ſhores is ſometimes found buried in the ſand, ſometimes naked on the ſurface of it, and ſometimes covered over with large bundles of the ſea-wrack, and other weeds. The vulgar have thought, from this laſt accident, that the *amber* was a gum flowing out of the leaves of thoſe plants, but that is a very abſurd opinion.

Sand, vitriol, and ochre, with a blue clay, are the ſubſtances which make up the principal part of the ſtrata in the cliffs; and the vitriol, in particular, ſeems to have ſome conſiderable ſhare in the formation of the *amber*, becauſe *amber* is ſcarce any where found foſſile, where there is not alſo vitriol: but neither of theſe ſubſtances can be properly called the matrix of the *amber*, ſince it is ſeldom found bedded in them; and when it is, only in ſmall quantities. The blue clay contains more *amber* than either of the other of theſe ſubſtances, but the true matrix of it is the wood, or cortical ſubſtance, which is found among theſe ſtrata, and of which alone there are immenſe hills in ſome places. Phil. Tranſ. Nº 248. p. 12. See the article MATRIX *ſuccini*.

The bodies of inſects, found buried in *amber*, are viewed with admiration by all the world; but of the moſt remarkable of theſe, many are to be ſuſpected as counterfeit, the great price, beautiful ſpecimens of this kind fell at, having tempted

tempted ingenious cheats to introduce animal bodies in ſuch artful manners into ſeemingly whole pieces of *amber*, that it is not eaſy to detect the fraud. The antients have deſcribed globes of *amber* with bees immerſed in them, and the cabinets of the modern virtuoſi afford many ſuch pieces; but Sendelius, after accurately examining many of theſe ſpecimens, ſuſpects them all to be ſophiſticated. Many ſpecies of the fly kind, however, are obviouſly and indiſputably lodged by nature there: among this tribe of animals, the ſeveral ſpecies of the ichneumon fly are found the moſt numerous; the common houſe and fleſh flies are alſo frequently found thus preſerved; and it is remarkable, that of theſe ſome have preſerved, and others have wholly loſt their natural colours. Theſe are ſometimes found in cloudy pieces of *amber*, but much more frequently in the perfectly clear and fine ones; and in theſe many are ſeen plainly to be encruſted with a thin coat of the matter of the *amber*, ſeparate from the maſs. Beſide the animals already named, the cabinets of the curious afford us numerous inſtances of the ſmall ſpecies of butterflies, the cricket, the graſhopper, beetles of various kinds, but theſe only ſmall ones, the larger and ſtronger being able to force their way out of the once viſcid maſs, and therefore never remaining entangled in it. Some of theſe, which are incloſed in it, are plainly ſeen to have ſtruggled hard for their liberty, and even to have left their limbs behind them in the attempt; it being no unuſual thing to ſee, in a maſs of *amber* that contains a ſtout beetle, the animal wanting one, or perhaps two of its legs; and thoſe legs left in different places, nearer that part of the maſs from which it has travelled. This alſo may account for the common accident of finding legs, or wings of flies, without the reſt of their bodies, in pieces of *amber*; the inſects, to which theſe have belonged, having, when entangled in the yet ſoft and viſcid matter of the *amber*, eſcaped, at the expence of leaving theſe limbs behind them. Drops of clear water are ſometimes alſo preſerved in *amber*. Theſe have doubtleſs been received into it while ſoft, and preſerved by its hardening round them. They are uſually contained in cavities too large for them, though ſometimes the holes are filled up. In ſome ſpecimens, the holes alone remain without any moiſture. Naturaliſts, who have been ſo curious as to examine this liquor contained in the *amber*, have found it to be of an auſtere taſte, like that in which vitriol had been diſſolved: others mention the having met with it wholly inſipid, and ſome taſting of ſea ſalt. It is eaſy to account for a drop of water, of any of the three kinds, being found in *amber*, but the vitriolic water is the moſt natural there, as there is always great plenty of vitriol where the *amber* is found. Some people, who have been poſſeſſed of pieces of *amber* thus containing water, have thought that the quantity was continually increaſing and decreaſing, according to the increaſe and decreaſe of the moon; but this is not countenanced by any certain obſervation. *Hartman*, Hiſt. Succin.

Amber, though fuſible with a ſmall fire, and concreting again when cold, yet differs from the metals, and other fuſible bodies of that kind, in this, that as ſoon as cold they are the ſame as before melting; but *amber*, when it has once been melted, is no longer *amber*, it loſes its beauty and hardneſs: and the true reaſon of this is, that being compoſed of bitumen and ſalt, the ſalt flies off in the heating, and leaves the remainder little better than the ſimple reſiduum of an evaporated petroleum, or any other liquid bitumen. There have been people, at different times, who have pretended to have an art of melting ſmall pieces of *amber* into a maſs, and conſtituting large ones of them; but this ſeems ſuch another undertaking as the making of gold, all the trials, that have yet been made by the moſt curious experimenters, proving, that the heat which is neceſſary to melt *amber*, is ſufficient to deſtroy it. Phil. Tranſ. N° 248. p. 25.

Hartman indeed mentions an accident, which ſhews a poſſibility of many pieces of *amber* being combined into one by an operation of nature, though it never could be effected by art. A ſheep was once killed in Pruſſia, in whoſe ſtomach a large piece of *amber* was found, which was compoſed of ſeveral other ſmaller pieces, the joinings of all which might be ſeen, though as firm as the pieces themſelves. This is a proof that the creature had ſwallowed the whole in ſmall pieces with its food, and that nature, by the heat and juices of its ſtomach, had ſoftened thoſe pieces without melting them, ſo as to make them unite firmly, though not be thoroughly blended with each other. Could art arrive at this, which it is not probable it ever will, even this is far ſhort of what is pretended of melting *amber*, and caſting it into what form is deſired. The factitious curioſities in *amber*, which are pretended to be pieces of this foſſil, with inſects embedded in it, are uſually no other than a hardened varniſh, not having the hardneſs, or other qualities of *amber*. Some few of them are *amber* melted, into which the inſects have been put in that ſtate, but theſe are very coarſe and brittle. Theſe two kinds of cheat are eaſily diſcovered by their want of hardneſs, and the other by obſerving the ſides of the piece, to find the joining where it has been ſplit.

Among the numbers of inſects thus preſerved, as ſome are covered within the maſs with a thin coat, or cruſt of pure *amber*; ſo others are covered with a cruſt of a white matter of a like thickneſs, but ſeeming different from the nature of the *amber*. The true cantharides are ſometimes alſo included in *amber*, and preſerving all the beauty of their colours there, they make a very ſplendid appearance. The ant is moſt frequently met with in pieces of *amber*; and the earwig is ſometimes found very perfect and beautiful in it. The ſpider kind afford very numerous ſpecies. The millepedes are not unfrequently met with. The ſcolopendræ appear in great beauty, when their bodies are twiſted and contorted, as not unfrequently happens in the large globes of *amber* where they lie. Caterpillars are alſo ſometimes found, but the ſoftneſs of their bodies has made them ſubject to great injuries, and they are often ſqueezed, compreſſed, and injured, ſo as ſcarce to be known.

Theſe are the ſpecies of land animals moſt frequently found in *amber*; to theſe ſome add the louſe and flea: and though theſe have brought great diſcredit upon all the inſects incloſed in *amber*, in the judgment of many, as ſeeming certainly counterfeit, yet Sendelius, who had carefully examined ſeveral of the maſſes in which they were found, and could find no trace of fraud in any of them, attempts to account for ſuch animals being naturally included in the ſubſtance of the *amber*, while yet ſoft, in the manner of the other inſects.

To theſe animals thus impriſoned, many authors add accounts of ſmall fiſh, young water newts, and other aquatic animals, but theſe ſeem in general to have been ſophiſticated maſſes; and indeed it is obſerved, that even the moſt common water inſects are very rare in *amber*. The way in which all the inſects, that are truly found lodged by nature in *amber*, were placed there, is not hard to gueſs, when we are ſo far acquainted with the nature of *amber*, as to be aſſured from experience, that it is at firſt a fluid, and by degrees becomes viſcid and thick like turpentine, from which ſtate it gradually hardens into the ſolid form we find it in; and this is ſufficiently proved; ſince there have been at times found quantities of true *amber* yet in its fluid ſtate; and the ſtructure of ſome globes of *amber* abundantly ſhew, that they have hardened from a fluid ſtate, ſome being plainly compoſed of ſeveral plates, and ſome containing a maſs of *amber* in another larger maſs; the internal maſs having undoubtedly hardened firſt, and the external, while yet in a fluid ſtate, gathered and concreted round it.

This being the manner of the including of the inſect tribe in *amber*, it ſeems that inſects alone ſhould not be ſubject to that fate, but that other matters, which fall in the way of the *amber* while yet ſoft and viſcid, ſhould ſhare the ſame fate. The locomotive power of the animal kingdom gives its creatures opportunities of falling into theſe maſſes, while vegetables and minerals have not; yet as theſe cannot but ſometimes fall in the way of the hardening matter of *amber*, they are ſometimes found immerſed in it. Beautiful leaves of a pinnated ſtructure, reſembling ſome of the ferns, or maiden-hairs, have been found in ſome pieces; but theſe are rare, and the ſpecimens of great value. Other leſs beautiful vegetable ſubſtances are more frequently found than theſe, though all of this tribe are ſcarce in compariſon to the animals. Small pieces of heath, and fragments of the alga, and ſome other plants, common about the ſea ſhores, are ſometimes found; as alſo ſmall fragments of wood, the ſeeds of ſome plants, and pieces of the ſtalks of others. Theſe are ſometimes found alſo, but a little way, buried in the *amber*, and at other times are only faſtened to its ſurface; the ſmall ſpecific gravity of theſe bodies, too little to immerſe them into the fluid, and the different conſiſtence of that hardening fluid, may have been the occaſion of theſe bodies having made their way into the maſſes but to ſmall depths: and indeed, if we conſider the whole proceſs, many happy accidents muſt concur to the perfect and beautiful immerſion of a foreign body in this bitumen.

Mineral ſubſtances are alſo found at times lodged in maſſes of *amber*: ſome of the pompous collections of the German princes boaſt of ſpecimens of native gold and ſilver in maſſes of *amber*; but as there are many ſubſtances of the marcaſite, and other kinds, that have all the glittering appearance of gold and ſilver, it is not to be too haſtily concluded, that theſe metals are really lodged in theſe beds of *amber*. Iron is found in various ſhapes immerſed in *amber*, and as it is often ſeen eroded, and ſometimes in the ſtate of vitriol, it is not impoſſible but that copper, and the other metals, may be alſo ſometimes immerſed in it in the ſame ſtrata; and that the bluiſh and greeniſh colours, ſometimes found in the recent pieces of *amber*, may be owing, like the particles of the gem colours, to thoſe metals; but as the gems, by their denſe texture, always retain their colours, this lighter, and more lax bitumen uſually loſes what it gets of this kind, by keeping ſome time. Small pebbles, grains of ſand, and fragments of other ſtones, are not unfrequently alſo found immerſed in *amber*. Theſe, it is very plain, have fallen into the maſs while not yet quite hardened; though things of this ſpecific gravity, when found lodged deep in it, muſt have fallen

fallen in when it was almoſt hard, otherwiſe they would have ſunk through. The pieces of *amber* including other pieces are alſo of this origin; and when it has happened that the included piece, and the ſurrounding maſs, have been of different degrees of colour, the inner piece is obvious, and the effect plain; but when theſe have been both of the ſame colour, which probably moſt frequently has been the caſe, we have no traces of the accident; and probably this, though by accident concealed, is a much more frequent caſe than is commonly imagined.

To all theſe accidental beauties in *amber* it is to be alſo added, that as in the Mocoa ſtones, and many other foſſils, ſo alſo in this there are ſometimes found beautiful delineations of trees, ſhrubs, and the like. The natural beauties of theſe pieces have tempted the cunning artificers ſometimes to counterfeit them; but in theſe, as well as in the ſophiſticated maſſes with inſects, the fraud may always be diſcovered by a curious and attentive inſpection. *Sendelius*'s Hiſt. of Amber.

On opening the ditches for the fortifications of Copenhagen, it is ſaid that ſeveral large maſſes of *amber* were found, all of them adhering to the ſides of large bodies of trees, which were black as ebony. The pieces are preſerved in the cabinet of the king of Denmark in that place, and ſome of them weigh forty or fifty ounces. This is an additional circumſtance to the common obſervation of ſomething, reſembling wood, being always found where *amber* is, and deſerves to be conſidered, as it tends to overthrow the preſent received ſyſtem, of *amber* being originally a mineral production.

Amber is the baſis of all varniſhes. For the method of diſſolving this ſubſtance into varniſh, ſee the article VARNISH. But if *amber* could be diſſolved without impairing its tranſparency, or one large maſs be made of it by uniting ſeveral ſmall ones, it is eaſy to ſee what would be the advantages of ſuch a proceſs. The art of embalming might poſſibly be alſo carried to a great height by this, if we could preſerve the human corps in a tranſparent caſe of *amber*, as the bodies of flies, ſpiders, graſhoppers, *&c.* are to a great perfection. Something of a ſubſtitute of this kind we have in fine roſin, boiled to a great hardneſs, and perfect tranſparence; this being diſſolved by heat, and the bodies of ſmall animals ſeveral times dipped in it, they are thus coated with colophony, that in ſome degree reſembles *amber*; but this muſt be kept from duſt. *Shaw*'s Lectures, p. 425.

Amber, in medicine, is given in its crude ſtate, only reduced to powder, as an aſtringent and balſamic. It is preſcribed in the fluor albus, in convulſions, and in all diſorders of the nerves. It is alſo given in coughs, and diſeaſes of the lungs; and is by ſome greatly recommended in inveterate head-achs. Its doſe is from one ſcruple to two.

Its preparations are, 1. *ſal ſuccini*, or ſalt of *amber*. 2. *Oleum ſuccini*, or oil of *amber*. 3. *Tinctura ſuccini*, or tincture of *amber*.

Oleum SUCCINI, or *oil of amber*. To purify the dark muddy *oil of amber* drawn *per ſe*, take two pounds of good brandy, one of ſea ſalt, half a pound of the oil; mix them, and diſtil them together, and a large proportion will come over very tranſparent, and finely coloured. *Boyle*'s Works, Vol. 1. p. 329.

Plants in SUCCINUM, or *amber*. See PLANTS.

SUCCURY, or SUCCORY, *cichorium*, in botany. See the article CICHORIUM.

The common blue-flowered *ſuccory*, or cichorium, is celebrated among ſome of the botanical writers for a property in its flowers, ſuppoſed to be peculiar to it, and eſteemed very ſingular; this is, that though naturally of a fine bright blue, they become red as blood on being a little time buried in an anthill. By what accident this property was diſcovered we do not know, but probably only by the falling of ſome of the flowers off from the plant into a neſt of theſe little animals. Langham, in his Garden of Health, has related this, but it is no diſcovery of his; for Tragus, long before his time, tells us, ſpeaking of this plant, that nature affords a miraculous phænomenon in its flowers, which is, that if put amongſt living ants in their hill, it changes from blue to red, as if bluſhing with ſhame and fear of ſuch numerous and ſmall enemies; and John Bauhine records the ſame thing from Otho Brunfelſius. It would have been well, if all who have related this wonderful change of colour, would have varied the experiment with the violet, and other blue flowers; they would then have found, that it was not the property of the plant, but of the animal, that was the true object of wonder. All blue flowers of plants will turn red on the rubbing them over with acids, and the wonder is, to find that the ants have a natural animal acid about them, capable of making ſuch a change; not that the flowers of the *ſuccory* are ſuſceptible of ſuch a change with acids. *Tragus* in Stirp. *John Bauhine*, Hiſt. Plant.

The method of making the experiment is this: lay bare the top of an anthill with a ſtick, and then throw ſome of the flowers of *ſuccory* on the place; the ants will immediately be ſeen to creep over them, and as they move along, they may be obſerved frequently to let fall a drop of clear water from the lower part of their bodies; wherever this falls upon the flower, it makes a large red ſtain; by degrees they let fall more of theſe drops, and every one making its own particular ſtain, the whole flower becomes at length coloured. Sometimes they make this change very quickly in the flower, and ſometimes they are a great while about it; but the body of the ant, bruiſed upon a leaf of the flower, will immediately ſtain the whole, ſo far as it reaches. It deſerves inquiry, whether the ants ſimply depoſit this liquor on the flower, or whether they make a wound or puncture on the ſurface of the flower firſt. The laſt is moſt probably true; becauſe this flower is covered with ſo thick an external membrane, that the acid ſpirits of vitriol, ſalt, or the like, being barely touched upon it, do not inſtantly change its colour; but if it be picked or bruiſed, ſo as to let in the liquor, the change of colour is then inſtantly produced. If the flowers of this plant be ſteeped in the ſtrongeſt vinegar for a long time together, they will not change colour while the menſtruum remains cold; but if it be heated a little, it is by that means put in motion, and rendered capable of entering the pores, and then the colour is inſtantly changed. It is not obſerved that the ant makes any puncture, and if it does not, it is evident, from the immediate change in the flower, where the ſtrong mineral has no ſuch effect, that the acid in this little animal is of a very peculiar nature.

It has been ſuppoſed by ſome, that the tingling felt in the ſkin, and the bumps raiſed on it by ants, are owing to the falling of this penetrating acid liquor, as the creature moves along. The venomous effect of the ſting of the bee and waſp, is ſaid by authors to be owing to the introducing into the wound a ſharp liquor, lodged by nature in this animal at the root of the ſting. It would deſerve a trial, whether the liquor of theſe creatures be of the ſame penetrating acid nature with that of the ant, which might be eaſily diſcovered, by forcing out the ſting of one of theſe animals by preſſure, and making it enter into the petal of the flower of a violet, bugloſs, *ſuccory*, or any other of the like plants. This liquor of the ants may eaſily be procured in ſome quantity from them. If their neſts be diſturbed with a ſtick, thruſt in among them, they will crawl about the ſtick, and leave a great number of the drops of their acid upon it, and theſe, if immediately ſmelt to, will twinge the noſe like newly diſtilled ſpirit of vitriol. The larger kind of ants, called by the country people *horſe-ants*, afford this liquor ſtronger, and in greater quantity, than the ſmaller, or common ants; and, on trials, it proves nearly allied to the mineral acids in its properties.

The ants, diſtilled either by themſelves, or with water, yield an acid ſpirit like that of vinegar, or of verdigreaſe, which is more pungent and penetrating. Lead put into this ſpirit affords a good ſaccharum ſaturni; and the ſame ſalt is produced from that metal, if only put into fair water with a large parcel of living ants in it, they ſoon parting with enough of their acid to make the water a menſtruum ſharp enough for diſſolving that metal. There is alſo ſomething very ſingular in this acid, which is, that it will preſerve itſelf, and be regained from the metalline admixture in its own nature. The common ſaccharum ſaturni being diſtilled, does not yield back the acid employed in making it, but only an inflammable oil and water; but the ſaccharum ſaturni, made by the animal acid of the ant when diſtilled, returns back that acid in the ſame quantity and ſtrength, and no way altered. The vinegar diſtilled from verdigreaſe, and called *ſpirit of verdigreaſe*, is an acid very like this, but ſtronger, and more penetrating. Phil. Tranſ. Nº 68.

SUCK-*fiſh*, in ichthyology, an Engliſh name for the *remora*, or *echeneis* of Artedi. See REMORA.

SUCKING (*Cycl.*)—Though there are very few inſtances of children which are born with an inability of *ſucking*, yet the writings of phyſicians have recorded ſuch caſes; and one, which happened ſome years ago in France, gave occaſion to the members of the Academy to examine ſtrictly into the cauſe of it. Mr. Maloet, who examined the child, found that it wanted the whole palate of the mouth, and that in looking up to the top of the cavity of the mouth, the inner part of the noſe was ſeen; the child not only wanted the bony parts which form this arch, but alſo the inveſtient membrane they are naturally covered by. Mr. Maloet conceived that he had now found out the reaſon of the child's not having the power to *ſuck*, which he explained in this manner.

In the action of *ſucking*, while the infant has in its mouth the nipple of the nurſe, the air about it is diſperſed, and there is made a little void all about it in the cavity of the mouth. At this time the whole breaſt is preſſed upon as uſual by the external air, though the nipple is not, or at leaſt is much leſs ſo, and hence the mouth performing the office of a pump, the milk contained in the breaſt cannot but diſcharge itſelf by degrees through the apertures in the nipple. In order to this, however, it is evidently neceſſary that the communication between the mouth and the noſe ſhould be ſtopped by the proper organs; ſince, if this were open, the air, which continually paſſes through the noſe in

refpiration, getting into the child's mouth, would equally prefs the nipple with the other parts of the breaft, and confequently the caufe of the iffuing out of the milk would no longer fubfift; the mouth being no longer capable of performing the office of a pump, than while it is empty. Hence, according to Mr. Maloet's account, the child born without a palate could not fuck, becaufe the nofe and mouth had, by the abfence of this organ, a conftant and uninterrupted communication.

This account however did not feem right to Mr. Petit, for thefe reafons: a void in the mouth is not at all effential, or neceffary to *fucking*, as appears every day by women's milking their cows; when, without any fuch void, and by the mere preffure of their hands, they get out the milk. All the mechanifm ufed here, is a continual fucceffion of ftroaking down the teat, one hand fupplying the place of another, and here is milk extracted without either a void, or a pump; and if the action of *fucking* be nicely obferved in an infant, it will be found to amount only to the fame thing. It feizes the nipple, and makes with its lips a fort of flefhy canal, which receives, and continues gently to prefs it. The lips are found by anatomy to be compofed of partly longitudinal, and partly tranfverfe fibres; in the action of feizing the nipple, the firft of thefe are extended as far as they are capable, and afterwards their natural contraction fqueezes the nipple, and does what the hands of the milker do on the cow's teat, preffing out the milk in the very fame manner. The fhape of the nipple being larger at its origin, than at the end, makes it eafily flide out of the child's mouth, and this gives the infant conftant occafion of laying hold of it higher up, and then if it flip a little, that is only a motion which, as the child's lips inclofe it round, will the more facilitate the flowing out of the milk, which is thus forced from above downwards. The lips of the infant, though they are thus affiftant, are not however the only organs employed in *fucking*, the jaws are of great ufe, by their force and power of compreffion, and the tongue is a very ferviceable affiftant.

The tongue in infants is extremely thin, tender, and flexile: this is applied clofely to the under part of the nipple, and when it afterwards is drawn down toward the bottom of the mouth, there is then indeed formed in that place a fort of void, which determines the milk to flow readily in there, efpecially as the tongue itfelf has before given the principle of fuch a motion. Nor is this all the ufe that Mr. Petit allows the tongue in *fucking*; he obferves, that the root of it may be as ferviceable to the child in the fwallowing the milk, as the tip of it was in getting it out of the nipple; for when the milk has been conveyed along it to the lower part of the palate, in the manner of a gutter, the root at that time preffing againft the œfophagus, compels the milk to run down it, and then the tip is again employed to the *fucking* out more milk; and the action of *fucking* is thus alternately relieved by fwallowing, and both greatly affifted by the tongue. It is very poffible, from the different ftructure of the parts, that in the infant firft mentioned, the root of the tongue might be incapable of its office of affifting in fwallowing, while the tip of it readily performed its office of *fucking*; and this Mr. Petit takes to have been the occafion of its death, for the child lived only five hours.

From this theory of *fucking* it is plain, that a child born without a palate may yet be able to *fuck* by means of its tongue. Mem. Acad. Scienc. Par. 1735.

We are told of a man's giving *fuck* to a child, and thereby rearing it; but we do not find any other evidence of the truth of the ftory, than the word of the man, or pretended man, who was a beggar. See Philof. Tranfact. N° 461. p. 813.

In the Philofophical Tranfactions we have an account of a woman, of fixty eight years of age, giving *fuck* to her grandchildren. This woman had not borne a child for twenty years, or upwards. It would feem, as if the *fucking* of the child had brought milk into the breafts. See N° 453. fect. 10.

SUCKING *fifh*, in ichthyology. See the article REMORA.

SUCU, in botany, a fpecies of apple-tree, faid to be frequent in the province of Canton in China. The fruit is dried like figs to be kept all the year, and is brought into Europe. It is fomewhat larger than our apple, almoft round, and of a reddifh colour, or fometimes green. When it is dry, it has a cruft refembling honey or fugar. *Hofm.* Lex. Univ. in voc.

SUDARIUM, in ecclefiaftical writers, the fame with *brandeum*. See the article BRANDEUM.

SUDIS, in zoology, a name ufed by moft authors for the fea pike, a fifh called by others *lucius marinus*, and *fphyræna*. See Tab. of Fifhes, N° 44.

It in fome degree refembles the common river pike, but is thinner in proportion to its length, and in fome degree approaches to the *acus*, or tobacco-pipe-fifh, in that particular. Its fcales are fmall, and its nofe long, and of a conic form, the under jaw running out a good way beyond the upper, and ending in a fharp point. Its mouth is very wide, and yellow within; its tongue large and narrow, and armed all along with fharp and fmall teeth. The jaws are furnifhed each with a fingle row of large and fharp teeth, fet at fome diftance one from another; and in the middle of the lower jaw is one tooth longer than the reft, which has a hollow in the upper jaw made to receive it. It has two fins on the back, which are both, but efpecially the fore one, very prickly; and the tail is very deeply forked. It is caught in the Mediterranean, and ufually fwims in fhoals together. Its ufual length is ten or twelve inches; and it is efteemed a very well tafted fifh. *Ray's* Ichthyogr. p. 273.

SUDORIFIC (*Cycl.*)—A fafe, eafy, and effectual *fudorific* may be prepared in the following manner. Take an ounce of refined camphor, beat it in a marble mortar with two ounces of blanched almonds, till it be reduced to a fmooth and even pafte. This may be formed into pills, or bolufes, and given, according to the ftrength of the patient, and other confiderations, from three grains to forty.

Sudorific, perfpirative, and alexipharmic medicines, make a large part of the common difpenfatories. A few medicines, well chofen, might fupply the place of all thefe; and of thefe one principal one would prove to be camphor, which trial will always fhew to be greatly fuperior to bezoar, Gafcoign's powder, lapis contrayerva, and the like. *Shaw's* Lectures, p. 227.

SVEGLIATO, in the Italian mufic, is ufed for a brifk, lively, gay manner of finging or playing. Thus they fay *maniera fvegliata*.

SUETA, in ichthyology, a name given by Bellonius, and fome other writers, to the *nafus*, a fpecies of cyprinus, according to the Artedian fyftem, and diftinguifhed by that author by the name of the *cyprinus* with the fnout ftanding prominent, in form of a nofe, and with forty rays in the pinna ani. See the articles CYPRINUS and NASUS.

SUFFIBULUM, among the Romans, a name given to the *prætexta* of the pontiffs, and *palla* of the Veftal virgins. *Pitifc.* Lex. Antiq. in voc.

SUFFIMENTA, *fumigations*, in pharmacy. The *fumigations* prefcribed by difpenfatory writers are reduced to two kinds; the one conducive to health, the other only to pleafure; and of each kind fome are of moift, or liquid ingredients, others of dry ones.

The *fumigations* for pleafure are compofed of fragrant and fweet-fcented fubftances, and are ufed in form of powders, troches, or medicated candles. The firft are ufually prepared of ftorax, benjamin, lignum aloes, cinnamon, camphor, mufk, ambergris, and civet, mixed in due quantities, and all reduced together to a powder. The fecond kind, or troches, are compofed of the fame kind of powdered ingredients, and are made into a pafte with a mucilage of gum tragacanth, and then cut into form. And the laft kind, or candle *fumigations*, are prepared of the melted fweet gums, with labdanum, made up into the form of large candles, with as much of the beforementioned fweet ingredients as can be received into the mafs. Thefe, though only meant for luxury and pleafure, yet have medicinal virtues; and as they abound in cordial fubftances, cannot but revive the fpirits, and refift contagion. The moift *fumigations* of this kind confift of the powders before named, blended among a large quantity of rofe and orange-flower water, and of folutions of ftorax, and other of the fweet gums in fpirit of wine.

The *fumigations* ufed to reftore health are of feveral kinds. Some are meant only as corroboratives, and thefe are compofed of much the fame ingredients with thofe ufed for pleafure; others are ufed to dry up abundant humors, to purge the lungs, or to promote the menfes. In all diforders of the uterus, there fhould be added to thefe *fumigations*, galbanum, caftor, and affa fœtida. A common *fumigation* is alfo ufed, by throwing tobacco on coals, and receiving the fmoak through a funnel; and to this are fometimes added colt's foot leaves, with other pectoral herbs, and a little fulphur. Thefe are very ufeful for drying up ulcerations of the lungs, and other diforders of the breaft.

The moift *fumigations*, for the fake of health, confift either of fome fimple liquor, fuch as vinegar, wine, aqua vitæ, or rofe water; and in fome cafes, as for the difcuffing hard tumors, a red-hot brick, or ftone, is thrown into vinegar, and the fteam is received on the part. This is alfo a *fumigation* often ufed in times of peftilential contagion, and that with great fuccefs. Decoctions of uterine herbs are alfo frequently ufed for *fumigations* in feveral diforders of the womb.

Olibanum, amber, ftorax, and balfam of Tolu, make a fine dry *fumigation* for a catarrh: and in hyfteric cafes, great benefit is often found from holding the head, with the mouth open, over a hot folution of an ounce of affa fœtida in a pint of ftrong wine vinegar.

SUFFITION, *fuffitio*, among the Romans, a kind of luftration, practifed by perfons who had attended a funeral; it was performed by walking over fire, and being fprinkled with water. *Pitifc.* in voc.

SUFFOCATIVE *catarrh*, in medicine, the name of a diſeaſe, which conſiſts in a copious eruption of a ſerous and mucous humor into the veſicles of the lungs; which takes its origin from a ſudden congeſtion of humors about the breaſt, and a flaccid and weak ſtate of the breaſt and lungs.

This diſeaſe is not to be confounded with the ſpaſtic aſthma; nor with a moiſt cough, treated injudiciouſly with expectorants and opiates; nor with that ſudden oppreſſion of the breaſt, which is brought on by the ſtriking back of rheumatic humors, or cutaneous exanthemata; or the ſtopping the diſcharges of old ulcers: all theſe, though they have ſomething of the general appearance of the *ſuffocative catarrh*, and are therefore miſtaken for it by the leſs judicious, yet differ greatly and eſſentially from it in ſeveral points; of which hereafter.

Another diſtemper, with which it is alſo confounded, and from which it no leſs differs, is that aſthmatic anxiety which attends young and plethoric perſons, who are unhappily labouring under a latent ſcirrhus, or vomica of the lungs. The *ſuffocative catarrh* differs as widely from this, as from any of the others; but as the cauſe of this is ſeldom gueſſed at firſt, it is liable to miſconſtructions. Others have confounded this diſeaſe with a convulſive aſthma. Theſe diſtempers are in a great meaſure to be diſtinguiſhed by the habit of body of the perſons afflicted with them; plethoric perſons, who abound in rich blood, being very ſeldom ſubject to this diſeaſe, though frequently to the convulſive aſthma. They are alſo diſtinguiſhed from the abundant afflux of matter in the *ſuffocative catarrh*, and by there being none in a convulſive aſthma. In the catarrh of this kind there is a relaxation of the tone of the muſcles of the breaſt; but, on the contrary, in this kind of aſthma they are continually contracted into convulſions; and hence there is, in this caſe, rather an actual preſſure and cohibition of reſpiration, than an impotence of it, which is truly the caſe in a *ſuffocative catarrh*. In this caſe alſo there is a remarkable loſs of the ſtrength, whereas, in the convulſive aſthma, there are violent efforts, and ſtrong palpitations of the heart. Some have alſo buſied themſelves in determining the differences between a ſerous apoplexy, and a *ſuffocative catarrh*; but this is not neceſſary, ſince they very often concur, and make but one diſeaſe: but when the ſerous apoplexy comes alone, it is known by having been preſaged by diſorders of the head, redneſs and lippitude of the eyes, a dull and heavy cephalæa, and a foaming, or voiding of frothy matter by the mouth. *Junker*'s Conſp. Med. p. 507.

Signs of a ſuffocative catarrh. This diſeaſe always ſeizes the patient at once, without any previous notice; his breath becomes extremely difficult, and the fullneſs of the breaſt is eaſily diſtinguiſhed by a ſound of rattling of a frothy matter at the time of drawing in the breath. There is an immediate debility and loſs of ſtrength and ſpirits, as the patient calls it, but there is in reality a ſpaſmodic tenſion; there follows this a reſtleſsneſs, ſo that the patient cannot ſuffer his limbs to lie a minute in the ſame poſture or place; and there is always a deſpondency in the mind, and the patient thinks he is certainly going to die. There is uſually either no cough at all, or, at utmoſt, only a very ſlight and inſufficient one, and the very ſtrength to cough is wanting. The breaſt, and even the ribs, are ſenſibly affected by this diſeaſe, and the eyes always look red and tumid.

Perſons ſubject to it. Scarce any one is ever ſeized with this diſeaſe, except ſuch as are, according to the common acceptation of the word, troubled with habitual catarrhs, or have for many years been ſubject to defluxions from the head upon the fauces and lungs; and the perſons moſt of all ſubject to it, are old men of a phlegmatic and plethoric habit, and are of that kind of temperament which ſubjects people, at other times, to palſies and apoplexies. Lean perſons are ſcarce ever afflicted with this diſorder, unleſs they have long laboured under a violent cough, or have ulcerous diſorders of the lungs. Young people are alſo very little ſubject to this diſeaſe, excepting only ſuch as are very corpulent and phlegmatic, and already habituated to large defluxions of this kind. Infants alſo, which are very fat, and have had a ſudden ſuppreſſion of their natural ſweats, ſometimes fall into this diſeaſe, but with them it is not ſo violent.

Cauſes of it. The occaſional cauſes of this diſeaſe are ſeen in what has been already obſerved, but its true origin is to be ſought for in the head, not in the breaſt or lungs; yet, though it is eaſy to ſee what may occaſion a congeſtion of ſuch ſerous humors in the upper parts, it is difficult to ſay how the lungs become rendered fit to receive it all at once in this dangerous manner. It is accidentally brought on in children, as well by the repulſion of their cutaneous eruptions, as by the ſtopping their ſweats; and in grown people, from the omiſſion of habitual bleedings, from coldneſs and dampneſs in the air, from frequent drunkenneſs, and from an injudicious treatment of cutaneous humors, and particularly from drying up runnings of the eyes. *Junker*'s Conſp. Med. p. 509.

Prognoſtics in it. It is a very terrible diſeaſe, and very ſpeedily proves fatal, for the patient, if not relieved, uſually dies in twenty four hours. Sometimes it degenerates into a fever; and the patient ſeems cured by the change; but the remedy in this caſe proves as bad as the diſeaſe; for the fever proves incurable, and becomes a ſettled hectic, attended with terrible difficulty of breathing, and finally carries off the patient, after making him endure, for ſome time, a life of terrible pain. Sometimes it goes off into an aſthmatic laxity of the breaſt, attended with a cough, and a continual diſcharge of large quantities of mucous matter by ſpitting; and ſometimes into an abſolutely cachectic flaccidity of the body: and in general, if not carefully treated from the beginning, it either entails ſome of theſe diſorders upon the patient, or leaves him ſo poor and weak a conſtitution, that he becomes eaſily liable to all the diſeaſes of this kind from the ſlighteſt occaſions.

Grown perſons are ſooner taken off by this diſeaſe than young children, with whom it ſometimes continues above a week or a fortnight. In old people, the fatal event of the diſeaſe is ſo ſudden, that it is often dubious whether it were this diſorder, or an apoplexy; and in general it ſeems probable, that many of the perſons, ſaid to die of apoplexies, die, in reality, of the violent attacks of this terrible diſeaſe.

Method of cure. In the time of the fit a ſtimulating clyſter muſt be given, made of a decoction of marjoram, and other warm herbs, with colocynth, and a few grains of euphorbium, in order to abate the infarction of the breaſt, and give a new courſe to the matter that might add to it; and when there appears to be a plethora beſides, a vein muſt be immediately opened after the clyſter. After this, if the ſtomach be nauſeating and uneaſy, let a ſcruple of ſalt of vitriol be given as a vomit, with a large quantity of warm water; and if the patient is of a very phlegmatic habit, a few grains of gamboge may be added to this, to carry the humor off downward; or, if the caſe be very preſſing, a draught of a decoction of aſarum, or of tobacco, may be taken, the bad effects of which laſt are taken off by a draught of wine with the ſpices; and all this time there may be frictions and ſinapiſms applied to the lower extremities: and finally, to attenuate and diſcuſs the mucous ſtaſis, gentle alexipharmics and ſudorifics may be given, ſuch as the eſſence of amber, tincture of ſalt of tartar, and tartariſed tincture of antimony; and all nitrous medicines are alſo of the greateſt uſe, as they partly mitigate the cauſes, and partly prepare the humors for evacuation; and after all theſe, the cortex elutheriæ is of great uſe in diſcuſſing and mitigating the pain.

As ſoon as the fit is over, the corroborating medicines are to be given, and all things that can reſtore the parts to their due tone: of this number are the milder chalybeates, and the like; and with theſe analeptics are to be given, to recruit the fleſh and ſtrength, ſuch as emulſions, and a proper diet; and in ſuch as are uſed to wine, the richeſt wines, in moderate quantities, and the higheſt foods, will be of ſervice. If there be perceived a fever after the other ſymptoms are gone off, this muſt be cured by the gentle alexipharmics, and by powders of nitre, and the abſorbents; and if a chronic indiſpoſition ſeems left behind, then the gums, which act as diſcutients, are to be given for ſome time, ſuch as the ammoniacum and ſagapenum, and a warm regimen is to be recommended. And finally, to prevent a return of the diſeaſe, bleeding is very proper in the ſpring and autumn, and purging medicines taken in the intermediate time; the patient muſt alſo avoid all violent paſſions of the mind, and muſt never ſleep in a damp air. We are not to fear bleeding in the time of the fit, becauſe of the patient's complaining of want of ſtrength; for as the danger of *ſuffocation* is ſudden and imminent, it muſt be ſuddenly removed, and when that is done, the patient's ſtrength will return in good time: the ſame is alſo to be alledged in favour of the violent vomits. In people of a very phlegmatic habit, bleeding is not neceſſary nor proper; but in theſe caſes a vomit is ſafe and right, and uſually gives great relief, eſpecially if the patient have eaten heartily ſome little time before. *Junker*'s Conſp. Med. p. 513.

SUFFOLK *powder*, the name of a medicinal powder, good for the bite of a mad dog. It had its name from a Counteſs of *Suffolk*, who uſed to give it with great ſucceſs. It is ſtill kept as a ſecret in ſome private families, but ſeems to be only the ſtar of the earth, or the common buckſhorn plantain dried and powdered, or this powder with ſome very trifling addition. This plant has been famous for its virtues in this caſe a great while among us, and De Grey, in his Complete Farrier, gives the method by which he had cured dogs by it with great ſucceſs. See Phil. Tranſ. N°450. p. 455.

SUGAR (*Cycl.*)—The curious in the whole art of *ſugar*-making, or the reducing vegetable juices to what we call *ſugar*, by expreſſion, decoction, clarification, graining, claying, and cryſtallization, will find farther accounts and directions, in the ſeveral proceſſes of this art, in Piſo's Hiſt. Ind. in Angelus Sala's Saccharologia, in Dr. Slare's Treatiſe on *Sugars*, and in Sir Hans Sloane's Hiſtory of Jamaica. There are alſo ſeveral valuable papers on theſe ſubjects in the Philoſophical Tranſactions.

Sugar has been said to be a specific against the famous Indian poison mentioned by Mr. de la Condamine; but this seems a mistake. See the article POISON.

Coarse *sugar*, in which there is more oil than in refined *sugar*, is recommended as a good medicine in Collyria for discharging ulcers of the cornea, in which astringents are hurtful. *Demour's* Diff. sur les Malad. des yeux.

Labourers in *sugar*-houses are very subject to dysenteries. The *vitrum antimonii ceratum* is an effectual remedy in these cases. See VITRUM *antimonii ceratum*.

Maple SUGAR. See MAPLE.

SUGAR *of milk*. See MILK.

SUGAR *spirit*, a name given by our distillers to a spirit made in England, Holland, and other places, from the washings, scummings, dross, and waste of a *sugar*-baker's refining-house. The manner of preparing it is the same with that used for the malt and melasses spirits. The refuse of the *sugar* is fermented with water in the usual manner, then distilled into what is called *low wines*, and afterwards rectified, without any addition, into proof spirit.

When the operation is well performed, and no foul fœtid, or foreign matter, has got in among the wash, this is a tolerably clean spirit. We usually make it such, but in Holland it is usually made very nauseous and disagreeable; though capable, by an easy rectification familiar with us, though not much known abroad, of being brought to a fine and clean spirit. With us this *sugar* spirit is used to mix with, and adulterate brandy, rum, and arrack, which will receive a large dose of it without its being at all discoverable; but the Dutch, who have it very coarse, can only adulterate rum with it, and even that will bear but a small proportion, without being betrayed by its nauseousness.

This *sugar spirit* reduced to alcohol makes one of the purest spirits we are acquainted with, much superior to that of melasses, and much more to that of malt. *Shaw's* Essay on Distillery.

We have, in the Philosophical Transactions, an account of a volatile and pungent spirit of sugar, which was made from what the *sugar*-bakers call *sugar-water*, which is no other than the water in which the aprons, moulds, and other utensils, employed in the refining of *sugar*, are washed. This was so extremely pungent, that a man could not smell to a large quantity of it without danger of suffocation; and so volatile, that no stopping it up could preserve its spirit for any length of time. Phil. Transf. Nº 130.

SUGGESTUS, among the Romans, a place in the *campus martius* raised higher than the rest, where every magistrate, according to his rank, was allowed to harrangue the people; but private persons could not, unless they first obtained leave from some magistrate to do it. *Pitisc.* in voc.

SUGGRUNDARIUM, among the Romans, a place where infants, not exceeding forty days old, were buried; it being unlawful to burn them. *Pitisc.* in voc. See the articles BURNING and BURIAL.

SUGITIVA, a term used by some authors to express medicines, which suck up and absorb the serosities in dropsical persons.

SUIT (*Cycl.*)—SUIT-*silver*, in our old writers, a small rent, or sum of money, paid in some manors to excuse the appearance of freeholders at the courts of their lords. *Blount*.

SUKOTYRO, in natural history, the Chinese name of a very large and remarkable horned animal, which seems to be the same with the carnivorous bull of Pliny and the antients.

It is of the size of a large ox; its head is shaped like that of a hog; its ears are long and hairy; and its tail is bushy. On each side of the head, near the eyes, there stands a large horn, resembling the ivory tusk of the elephant, but not altogether so thick. Nieuhoff, who gives this account, adds, that it is very rarely caught, and that it feeds on grass; but this last observation may possibly have been spoken of course, without any one's having certainly known it. All that we have ever seen of this animal, is a pair of horns of an enormous size, now in the possession of Sir Hans Sloane, and of which he has given an account to the Academy of Sciences at Paris.

These were found in some part of Wapping, by Mr. Doyly, the inventor of the English stuff of that name, in a cellar he had hired; they were much injured by time, and in many places rotten, and worm eaten. No one could remember any account of the place whence they came, or how they were brought to that place.

They are strait for some distance from the base, but higher up they begin to bend, and go on crooked to a point. They have much more of the external appearance of the horns of the goat, than the ox kind, being not round, but flatted, and variously undulated with high transverse ridges and furrows. They are not both exact in length, but the longest measures six feet, six inches and a half in length. The diameter at the base is seven inches, and the circumference there a foot and a half. The weight of the largest is nearly two and twenty pounds, and it will hold in its cavity a gallon and a pint of water; and would hold much more, were it not for the worm-holes near the base.

The captain of an East-Indian ship, on seeing these horns, assured Sir Hans that they belonged to a large species of bull in the East, which he had seen, and which, by his account, seemed to be the same with the creature before mentioned, as described by the antients; though none of the modern naturalists having seen it, it has been left out of their accounts. Agatharcides, who lived about a hundred and twenty four years before Christ, has well described this animal; and whatever has been occasionally spoken of it by any others, is all transcribed from his writings. The creature seems to be a native only of Ethiopia, some few parts of the East-Indies, and some inland countries in Africa, never visited by our travellers. From all the accounts we have, its size appears to be, at least, twice that of our ordinary oxen, and with horns proportionably large. The pair here mentioned seem not to be the only ones preserved in Europe, for Gesner tells us of one of an enormous size, which is still hung up in the cathedral church of Strasburg. Mem. Acad. Par. 1727.

SULA, in zoology, a name given by Hoier, and some others, to a bird, described as a distinct species of the webfooted water-fowl, but seeming to be no other than the *anser bassanus*, or soland goose. *Ray's* Ornitholog. p. 249.

SULCATED *leaf*, among botanists. See LEAF.

SULMO, in ichthyology, a name given by Bellonius, and some others, to the salmon.

SULPHUR, (*Cycl.*) in natural history. *Sulphurs* are defined to be dry, solid, but friable fossile bodies, melting with a small heat, when fired in the open air, burning almost wholly away with a blue flame and noxious vapour, indued with an electric power, and not dissoluble in acids.

Some have used the word *sulphur* as a name for the whole series of inflammable bodies, but as we have also been used to distinguish those of a particular kind by the same name, it seems much more eligible to restrain that name to those bodies, and to give some other for the more general classes.

The word *sulphur*, in this acceptation, becomes the name of a regular genus of fossils, of which there are four known species. 1. The yellow native *sulphur*, which in its purest state is of a pale straw colour, and as pellucid as the finest amber; but is more frequently found coarser, and more opake. It is found in the gold mines of Peru, in Hungary, and in some other places. 2. The green native *sulphur*. This is harder than the other, and is usually found in small masses composed of several crusts. It is found, so far as is yet known, only about mount Vesuvius. 3. The grey native *sulphur*, which is common in Iceland, and many other places, and is the coarsest and worst of all the kinds. And 4. the most rare and beautiful of all the kinds, the red native *sulphur*. This is of a fine glowing red, like cinnabar, and very bright and transparent, and is found, so far as is yet known, only in the gold mines of Peru. *Hill's* Hist. of Foss. p. 402.

Mr. Homberg having given the original composition of *sulphur*, in his accurate analysis of that mineral, Mr. Geoffroy attempted to bring that analysis to the nicest test, by composing *sulphur* out of such substances as appeared to be its constituent principles.

It appeared from Mr. Homberg's analysis, that what passed in the earth for the production of *sulphur*, was, that the vitriolic acid, and the common mineral bitumen; both which are always found in great abundance in all places where native *sulphur* is produced, being joined by a long digestion under ground, and mixt with some of the native alkalis of the earth, by an intimate union of all three together, formed one mineral *sulphur*. The best way of trying the justness of this hypothesis, was by attempting to make *sulphur* with the same substances by a chemical digestion. With this view Mr. Geoffroy mixed the perfectly deflegmated spirit of *sulphur* with an equal quantity of Mr. Homberg's balsam of *sulphur*, carefully prepared; after digesting these alone for some time, he added some oil of tartar by way of alkali, and then gave the whole a new digestion. After this the whole being distilled by the retort with a brisk fire, there came over into the receiver some phlegm, and a little oil; and when the vessels were cooled, there was found in the retort a saline matter, yellow in some parts, and red in others, and every where smelling very strongly of *sulphur*. He made a lixivium of this substance, filtered the clear liquor, and adding distilled vinegar to it, the liquor became turbid, and smelt strongly of *sulphur*, and, in fine, precipitated a white powder, which was true *sulphur*, and would burn wholly away.

This was the first experiment: the next was to try whether other substances, of the nature of those separated from *sulphur*, would produce a true *sulphur* in the same manner. For this purpose the substances fixed upon were oil of vitriol for the acid, and oil of turpentine for the bitumen; equal quantities of these being mixed together, the whole became very hot, and after standing some time it became red, and had an agreeable smell, like the citron: this however, in longer standing, became stronger, and less agreeable. The mixture having stood till it was considerably thick, there was added to it a quantity of oil of tartar; the whole then fermented together for a long time, but not with any great violence,

violence, after which it became a thick soapy liquor. Part of this was distilled, and yielded by the retort a yellow transparent oil, of a strong smell, and an acrid taste, and a phlegm of a like acrid taste: after these there came over a thick brown oil, sweet to the taste, and smelling like the oil of wax; and after this there followed a substance, wholly resembling the butter of wax. At the bottom of the retort there remained a saline matter of a very strong *sulphureous* smell, resembling also the stink of rotten eggs: this matter being dissolved in water, and distilled vinegar poured on the solution, the whole became turbid, and, in fine, precipitated a grey powder, which proved true sulphur.

Thus was the process of nature fairly imitated, and a mineral substance produced by a mixture of bodies not drawn from that mineral. The author, after this, was desirous to shorten the operation, dried the remainder of the first mixture over an open fire; then putting it into a red-hot crucible it flamed, and emitted a smell wholly resembling that of olibanum when burnt; and after that a very penetrating smell of *sulphur* issued from it. The whole being then taken from the fire, part of it was yellow, and part red, but all had the smell of *sulphur* very strong.

The vitriolic acid is not peculiarly necessary in the making of *sulphur*, for the spirit of alum was found to finish the process in the same manner.

As it appeared, that in the course of this process there had been made a tartarum vitriolatum, by the mixture of the oil of tartar with the acid spirits, Mr. Geoffroy was induced to try whether the common tartar vitriolate would not answer the purpose, and the event proved, that this salt, mixt with any of the inflammable oils, would yield a burning and true *sulphur*; and not only this salt, but many others of a like kind, answered the same purpose. The salt, produced by mixing oil of tartar and spirit of *sulphur*; colcothar, or fixed salt of vitriol; Glauber's salt, which is a composition of the acid of vitriol, fixed by the alkali of sea salt; and burnt alum, which is the vitriolic acid, mixed with a large portion of earth, all made genuine *sulphur*, on being properly mixed with the inflammable oils. Another way of making this mineral is thus.

Mix together one ounce of the salt of colcothar with two drachms of salt of tartar; melt them together over a fierce fire, and as they begin to fuse, throw in, at several times, an ounce of rectified spirit of wine. When the whole ceases to fume, it will yield a very penetrating smell of *sulphur*; take it from the fire, and the flame will appear bluish. When it is cold, the matter will appear yellow in some places, and red in others, as in the former processes, and will smell very strongly of *sulphur*, or of rotten eggs. Make a lixivium of this matter, and pour distilled vinegar into it, and a true inflammable *sulphur* will be produced, in form of a precipitate, at the bottom of the vessel.

The salt of tartar, in this mixture, serves only to assist the fusion of the colcothar, and to render the mixture of the spirit with it more exact; but it appears very wonderful, that so volatile a *sulphur*, as that of spirit of wine, should be able at once to unite and fix itself in mixture with a fixed salt in fusion. Nor is spirit of wine any more essential in this process, than any peculiar acid in the former, since petroleum, oil of amber, oil of turpentine, or any of the fetid oils of animals, in the same manner produce *sulphur* with these salts. Nay, any inflammable matter mixt with these salts, whether charcoal, common pit coal, or whatever else of the same kind, will produce *sulphur* in the same manner, though in different proportions.

Decrepitated sea salt and fixt nitre were tried in the manner of the former salts, but they would not yield any *sulphur* on a like process. These several experiments all join in proving the truth of Mr. Homberg's observation, that *sulphur* is composed in the earth by a mixture of an acid spirit, a bituminous oil, and an alkaline earth; and do great honour to that elaborate analysis by which he discovered it.

Mr. Geoffroy, though he carried the art of making artificial *sulphur* to these great lengths, is not however the first author who attempted it, Mr. Boyle and Glauber both did it before him, but on different plans; Mr. Boyle by a mixture of oil of vitriol and oil of turpentine, and Glauber by a mixture of his own salt and powder of charcoal; but though both succeeded in some degree, neither process could be compared with these, nor the *sulphur* be made near so pure. Mem. Acad. Par. 1704.

Stahl's method of producing *sulphur* is very easy, and is thus performed. Mix with tartar vitriolate, in order to facilitate the melting of that refractory salt, an equal quantity of potash, and add to this an eighth part of soft powdered charcoal; put this mixture, at several times, into a red-hot crucible, and cover it with a tile, lest a great quantity of the phlogiston should be dissipated by the fire; the mixture will soon melt, and there will be produced a true *hepar sulphuris*, or liver of *sulphur*. When this is dissolved in cold water, true *lac sulphuris* may be precipitated from it; and this may be sublimed into true and perfect flower of brimstone. *Cramer's* Art of Assaying, p. 390.

The purest gold, when melted with common *sulphur*, remains perfectly the same as before; it lets the *sulphur* burn freely away, remaining itself entire, and in a mass. Silver, when it begins to grow red-hot in a crucible, melts immediately on adding common *sulphur*; and when poured out, it proves a mass that cuts very easily, is very malleable, and is of the colour and consistence of lead: this mass, however, being a second time exposed to a very strong fire for a considerable time, is freed from its *sulphur*, which becomes dissipated, and the silver germinates into a kind of woolly substance, if the fire be slackened toward the end of the operation.

Tin, granulated and stratified with an equal, or double quantity of *sulphur*, deflagrates in the fire as if nitre had been added, and leaves the fluid, which becomes solid and consistent while it is yet red in the fire; whence it is plain, that the fusion of tin is retarded by *sulphur*. The remaining regulus is very brittle under the hammer, much like a semi-metal, and is of the colour of lead; but the part of the tin, thus turned into scoriæ, looks like ashes and dust upon the surface, but is darker coloured, and cleaner within. The whole quantity of the tin will be converted into these scoriæ, by repeating the burning with fresh quantities of brimstone.

Lead melted with brimstone, after the deflagration, is reduced to a mass which is hardly fusible by a great fire, but forms a friable mass, consisting of very bright and glittering particles.

Copper stratified with *sulphur* melts immediately in the fire, and turns to a black brittle mass. The same thing also happens, if *sulphur* be put upon copper when red-hot. Iron being taken red-hot out of the fire, and rubbed with *sulphur*, melts into a spungy dross; it afterwards quits this *sulphur* with difficulty, but melts very easily with it. There is no metal, or semi-metal, that seems so nearly allied to iron, as *sulphur*, or that melts so easily, and remains so intimately mixed with it. Regulus of antimony being well powdered, and mixed with *sulphur*, and stirred with an iron while in fusion, returns into crude antimony again. The fusion of crude antimony is also greatly promoted and assisted by common *sulphur*; but it does not mix so readily with the *sulphur* as the regulus.

Bismuth melted with common *sulphur* runs into a mass resembling antimony, of a faint grey colour, consisting of minute and very bright needles, each cutting the others across: this mass is extremely brittle.

Zink melted with *sulphur* does not readily mix with it, but if it be kept a long time in a moderate fire, and *sulphur* be many times poured over it, so as to cover the whole surface, and it be continually stirred together, it at last produces a very brittle dark-coloured shining substance.

From these experiments with *sulphur* on the metals it appears, 1. that iron being very greedy of *sulphur*, all the other metals, and semi-metals, may be freed from *sulphur*, by adding iron to them. 2. That a very small quantity of iron, a greater quantity of copper, and a much larger of lead, or tin, are necessary to absorb the same proportion of *sulphur*. *Cramer's* Art of Assaying, p. 43.

Dr. Lister has given it as his opinion, that there is no such thing as pure mineral *sulphur* found native, or in its original state, in the earth. He supposes all the pyrites to contain a vast quantity of *sulphur*, as indeed experience proves; and is of opinion, that as we by art can, by means of fire, melt and separate pure *sulphur* from the pyrites, so nature, acting by subterranean fires, can do, and frequently does the same; and that the *sulphur*, found pure about the burning mountains, and in mines, is all of this kind. He supposes, also, that thunder, lightning, and earthquakes are all owing to this matter; and that it is owing to the exhalations of the pyrites, which are in effect the pyrites itself. Philos. Trans. N° 156.

It is evident, from numerous experiments, that vitriol and *sulphur* are things very nearly allied to one another. The vitriolate salt, in common *sulphur*, differs scarce at all from common vitriol, and the acid liquors obtained from both, under the different names of *spirit of sulphur*, and *oil of vitriol*, are the same, except in degree of strength.

The effects of these two acids in the body, and also on metals, *&c.* are exactly the same. It is observed, that the *sulphur* yields but a very small quantity of this acid, in comparison of the vitriol; but the reason of this is, that in the operation the rapid motion of the flame sublimes the far greater part of the substance, unseparated in the form of flowers.

There are ways however of remedying this, and by some such means it was that the famous Drebbel obtained, at the rate of eight, and sometimes ten ounces of spirit, from a pound of *sulphur*; whereas, in the common process, one ounce is a considerable quantity to obtain. Possibly the grand secret, Mr. Ward possesses at present, of making oil of vitriol, as he calls it, cheaper than others, may depend on this sort of contrivance. The vessels he uses are vast spheres of glass, of three feet in dameter, which must serve as well, at least, if not much better, than bells; and oil of *sulphur*, and oil of vitriol, are so much the same, that there is no deceit in selling the one for the other.

In

In all the operations for the making oil of *ſulphur*, the weather is a material thing to be regarded; for when the operation is performed in moiſt weather, there is always a greater quantity of ſpirit or oil prepared, than when in dry; and Drebbel acknowledged, that he could obtain one fourth more in theſe, than in other ſeaſons. This great chemiſt tells us, that he was convinced the contrivance he uſed was capable of very great improvements, and that he made no doubt of carrying it ſo far, at length, as to obtain an equal weight of acid ſpirit to that of the *ſulphur* uſed in the experiment; the humidity of the air, at leaſt, adding as much as the quantity of the *ſulphur* loſt in the operation. There are ſeveral common menſtrua, by means of which *ſulphur* may be reduced into the form of a highly-rectified acid, and corroſive liquor; and even ſpirit of nitre, or aqua fortis, well rectified, being digeſted upon the flowers of brimſtone, and then diſtilled in aſhes, and the proceſs repeated five or ſix times after the laſt operation, there will remain with the flowers nearly an equal weight of an acid ſpirit, in all things reſembling that made by the bell, the ſpirit of nitre being ſcarce at all changed from what it was before the operation: and it ſeems, from experiment, that if the proceſs were frequently reiterated, and the ſpirit of nitre changed, the whole may be thus tranſmuted into an acid ſpirit, abating only for ſome ſmall proportion of earthy, or metalline particles. Phil. Tranſ. N° 104.

There is a preparation of common *ſulphur*, ſtrongly recommended by Mortimer for preſerving timber from being worm eaten, as it is very ſubject to be when felled before the ſap is wholly at reſt. A quantity of common yellow brimſtone is to be put into a common retort of glaſs, and covered three fingers deep with aqua fortis; this is to be diſtilled off to a dryneſs, and the ſame repeated three times. The *ſulphur* then is to be taken out, and laid on a marble, or put into an open flat glaſs veſſel, where it will ſoon run into an oil by deliquium. This oil is to be rubbed on any curious piece of wood that is in danger of worms: it will deſtroy them if they have begun to breed in it, and wholly prevent them if not yet begun. It alſo gives the wood an agreeable tinge or colour, which no art can ever rob it of afterwards. It is alſo a great preſervative of wood that is to be ſet in the earth, or under water; and may be uſed with ſucceſs to rub over the cables in ſhipping, or any other ropes that are indangered by lying much in the water. *Mortimer*'s Huſbandry, Vol. 2. p. 104.

SULPHUR, in medicine, is given in its crude ſtate with great ſucceſs in diſeaſes of the lungs: it ſtrengthens and cleanſes them, by promoting expectoration. It has always been famous for its virtues in cutaneous diſeaſes, and in hæmorrhoidal complaints. It generally proves a little looſening to the bowels, and increaſes the diſcharges by perſpiration: it even communicates its ſmell to the perſpired matter for a conſiderable time after taking it, and will often blacken gold or ſilver that is worn by people who take any conſiderable quantity of it.

The preparations of *ſulphur* are, 1. *flores ſulphuris*, flowers of *ſulphur*. 2. *Sulphur precipitatum*, commonly called *lac ſulphuris*. 3. *Balſamum ſulphuris*. 4. *Aqua ſulphurata*. 5. *Spiritus ſulphuris*, the oil, or ſpirit of *ſulphur*.

SULPHUR *of antimony*. The method of Angelus Sala for preparing the *ſulphur of antimony* ſeems, according to Dr. Plummer, preferable to the common way. The curious may find the deſcription of Sala's in the Medic. Eſſ. Edinb. Vol. 1. Art. 6. The doctor thinks, that in the common preparation much of the true *ſulphur* is conſumed by the deflagration, and the precipitated powder conſiſts of many of the groſs earthy parts of the ſalts in antimony. However, the *ſulphur of antimony*, uſed by the doctor in the preparation of his *æthiops*, was made in the common way. See PLUMMER's *æthiops*.

SULPHUR *auratum*, a name given by ſome chemiſts to a preparation of *ſulphur* and arſenic, called by others *rubinus arſenicalis*. See RUBINUS.

Balſam of SULPHUR. See BALSAM, *Cycl.*

Embryonatum SULPHUR. See EMBRYONATUM.

Fixed SULPHUR. *Fixed ſulphur* is uſed by the enamellers, and is prepared in the following manner. Boil flower of brimſtone in common oil for an hour; take the matter off the fire, and pour on it a quantity of very ſtrong vinegar, the flower of brimſtone will on this ſink to the bottom; pour off the liquors, and repeat the operation to the third time, and the powder then ſeparated is the *fixed ſulphur*. *Neri*'s Art of Glaſs, p. 188.

Spirit of SULPHUR. The uſual methods of preparing the acid *ſpirit of ſulphur*, or oil of *ſulphur*, by the bell, are ſo tedious and expenſive, that few are at the pains to make it. Both the methods, deſcribed by Mr. Charras in the Pharmacop. Royale, p. 883, are liable to many uncertainties and inconveniencies, as well as that recommended by Mr. Homberg in the Memoirs de l'Acad. des Sciences, anno 1703. In the Medical Eſſays of Edinburgh, Vol. 5. Art 14. we have an eſſay on extracting the acid of *ſulphur* in an eaſy manner, by placing a crucible with about three ounces of flower of *ſulphur* in it under a retort. The *ſulphur* being fired by throwing a lighted coal into it, the crucible is then gradually raiſed till it be juſt received within an orifice cut in the bottom of the bole of the retort, to which a large receiver with a ſpout is adapted. When the *ſulphur* is conſumed, the ſame quantity of new lighted *ſulphur* is to be put into another crucible; and thus the proceſs may be continued, till as much acid is obtained as is required. See the book loc. cit. or the Abridgment, Vol. 1. p. 160, ſeq. for the details of practice.

This method is indeed an improvement on the common one; but there are two other more elegant and eaſy ways of extracting the acid from *ſulphur*. The firſt is by Stahl, who directs woollen cloths to be moiſtened in a ſolution of fixed alkaline ſalt, and then dried. Theſe are to be ſuſpended over the fume of burning *ſulphur*, which will be imbibed and locked up in the ſalt, from whence it may be eaſily ſeparated by the addition of oil of vitriol, and the aſſiſtance of common glaſs diſtilling veſſels.

The ſecond is by Mr. Seehl, who pours oil of vitriol on a *hepar ſulphuris* placed in a glaſs retort, to which he adapts a receiver, and by a ſmall heat draws off the acid liquor. See Improvement on making Volatile *Spirit of Sulphur*, by Ephr. Rinh. Seehl, Lond. 1744. and Medic. Eſſ. Abridg. Vol. 1. p. 164. Not.

A pound of flowers of *ſulphur* may be burnt in about ſeven or eight hours, and will yield about ſeven drachms, or an ounce of pure acid. But it is obſervable, that the quantity of acid liquor varies greatly with the weather, being, as before mentioned, conſiderably more when the air is moiſt, than when it is dry.

It is ſaid that *ſulphur* may be made by contriving a fat, oily, or bituminous ſubſtance, with any mineral acid ſalt; but, in reality, the difficulty of making *ſulphur* with every acid is very great, if not impoſſible. With the vitriolic acid, indeed, the inflammable part of bodies eaſily combines into a true *ſulphur*; but it does not appear that any way has yet been found, by which the marine or nitrous acid may directly be combined into ſuch a ſubſtance. Stahl is expreſsly of this opinion in his Opuſcul. Phyſ. Medic. 4to. See Medic. Eſſ. Abrig. p. 163. Not.

Oil of SULPHUR. Some think there is an eſſential difference between the acid of *ſulphur* and its ſuccedaneum, the oil of vitriol; but a late author aſſerts, notwithſtanding the experiments brought to ſupport this opinion, that if the two acid liquors be reduced to the ſame ſtrength, and perfectly freed from all heterogeneous ſubſtances, they will be perfectly ſimilar, and not to be diſtinguiſhed. See Eſſay for Reforming of the London Pharmacopœia, London, 1744. p. 64.

SULPHUR *præcipitatum*, a name given in the London Pharmacopœia to the medicine called by other authors *lac ſulphuris*, or milk of *ſulphur*. It is by ſome directed to be made with the addition of an alkaline ſalt, but according to the method now in uſe, is thus prepared. Boil flowers of *ſulphur* in water, with three times their weight of quick lime, till they are thoroughly diſſolved; filtre the ſolution through paper, and pour on it weak ſpirit of vitriol, till a precipitation is procured; ſeparate the precipitated matter, by pouring off the water, and waſh it with freſh water, till it is become quite inſipid. *Pemberton*'s Lond. Diſp. p. 210.

Purified SULPHUR, is uſed in the making of gunpowder, and other occaſions. The method of preparing it at the powder-mills is this: they diſſolve the *ſulphur* by a very gentle heat, and then ſkum it, and paſs it through a ſtrainer. If the brimſtone ſhould happen to take fire in the melting, they have an iron cover that fits on cloſe to the melting veſſel, and damps the flame. The brimſtone is judged to be ſufficiently refined, if it will melt without yielding any fetid odour between two hot iron plates, and be changed into a kind of red ſubſtance. *Shaw*'s Lectures, p. 389.

SULPHUR *rapax*, in chemiſtry, a name given to arſenic, from its carrying off a great quantity of many metals in the fire, which it carries up with it, and ſublimes in form of flowers, called by ſome *cadmia fornacum*.

Volatile acid of SULPHUR. The *volatile acid of ſulphur*, according to ſome, contains not only the oil of *ſulphur*, but, at the ſame time, the pure native *gas*, or highly volatile ſpirit of the *ſulphur*. Mr. Seehl has given us an eaſy method of procuring this *volatile acid of ſulphur*, which he thinks of ſuperior virtue, both as a menſtruum and as a medicine, to the oil of *ſulphur* by the bell. For this purpoſe he gives us two proceſſes; one with an alkaline ſalt *per ſe*, mentioned above; and the other, which he prefers, by means of the ſame ſalt, with the addition of quick lime. See Phil. Tranſ. N° 472. The ſpirit, obtained thus by quick lime, is ſtronger, more acid, and more volatile, although ſpecifically heavier than the former.

The caput mortuum, remaining after diſtillation, makes an excellent tartar of vitriol, by ſolution, filtration, and cryſtallization. Ibid.

SULPHUR-*water*. See AQUA *ſulphurata*.

SUMA, a name given by ſome of the chemical writers to tartar.

SUMAGE, SUMAGIUM, or SUMMAGIUM, in our old writers, toll for carriage on horseback. *Pro uno equo portante summagium per dimidium ann. obolum. Chart. de Foreſt.* cap. 14. *Crompt.* Juriſ. 191. Terms of Law. *Blount, Cowel.*

SUMEN, a word uſed by ſome anatomical writers to expreſs the hypogaſtrium.

SUMMER (*Cycl.*)—It is ſaid, that a froſty winter produces a dry *ſummer*; and a mild winter a wet *ſummer*. It often happens ſo, in fact; but why it ſhould be ſo, is perhaps a queſtion difficult to determine. The curious may, on this ſubject, conſult the Philoſophical Tranſactions, N° 458. ſect. 10.

SUMMER *teale*, in zoology, the name of a bird, the ſmalleſt of all the duck kind, called by Geſner the *anas circias*. See the article CIRCIAS.

SUMP, in metallurgy, a round pit of ſtone lined with clay within, for the receiving the metal on its firſt fuſion from the ore. *Ray*'s Words, p. 114.

SUMP, in the Engliſh ſalt works, where ſea water is boiled into ſalt, is uſed as the name of a ſort of pond, which they make at ſome ſmall diſtance from the ſaltern on the ſea ſhore, between full ſea and low water mark. From this pond they lay a pipe, through which, when the ſea is in, the water runs into a well adjoining to the ſaltern; and from this well they pump it into troughs, through which it is carried to their ciſterns, in order to be ready to ſupply the pans. See the article SALT.

SUN (*Cycl.*)—SUN-*fiſh*, *mola*, in ichthyology. See Tab. of Fiſhes, N° 27. and the article MOLA.

One of theſe fiſhes, of five hundred weight, was taken ſome years ago near Plymouth, and on boiling a piece of the fleſh, to try how it would taſte, (as ſome authors have deſcribed it as a fine fiſh for the table) it was found, inſtead of a firm maſs, to be all converted, in a few minutes, into a perfect jelly, ſo that it could not be taken out otherwiſe than with a ſpoon. In colour and conſiſtence this jelly reſembled boiled ſtarch when cold, and had little or nothing of a fiſhy flavour, but a very agreeable taſte; it ſtuck firmly to the lips, however, and to the fingers, appearing very remarkably glutinous: and as the antients had no other glue than one made of fiſh, this jelly was tried, as to its ſticking quality, on leather, and on paper, and was found to anſwer as well as common paſte; but by ſome accident it was not tried upon wood.

It will be extremely worth while, on ſome other opportunity, to try whether a true ichthyocolla may not be prepared, by boiling down this jelly. Philoſ. Tranſ. N° 456. p. 220.

SUN-*flower*, *corona ſolis*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the radiated kind; its diſk is made up of floſcules, and its outer edge of ſemifloſcules; theſe ſtand upon the embryo ſeeds, and are ſeparated from one another by little leaves of an imbricated figure, and contained in a ſcaly huſk, or cup: the embryos finally ripen into ſeeds, furniſhed with two little leaves.

The ſpecies of *ſun-flower*, enumerated by Mr. Tournefort, are theſe. 1. The common great *ſun-flower*. 2. The great branched *ſun-flower*. 3. The great *ſun-flower* with greyiſh white ſtriated ſeeds. 4. The perennial *ſun-flower* with large flowers and large ſeeds. 5. The leſſer, or female *ſun-flower*. 6. The ſmall-flowered *ſun-flower* with tuberous roots. 7. The ſmall-flowered *ſun-flower* with long roots. 8. The talleſt broad-leaved *ſun-flower*. 9. The tall *ſun-flower* with alated ſtalks. 10. The rapunculus-rooted *corona ſolis*. 11. The ſmall-flowered large-leaved *corona ſolis*. 12. The throat-wort-leaved *ſun-flower* with creeping roots. 13. The golden-rod-leaved very tall *ſun-flower*. 14. The creeping narrow-leaved *ſun-flower* with pale yellow flowers. 15. The willow-leaved *ſun-flower* with alated ſtalks. 16. The ſhrubby American *ſun-flower* with lychnis leaves, and yellow flowers. 17. The ſhrubby American *ſun-flower* with ſpurge-laurel leaves, and yellow flowers. 18. The dwarf ſea American *ſun-flower* with fleſhy three-pointed leaves, and yellow flowers. 19. The ſmall *ſun-flower* with deeply jagged leaves. 20. The *ſun-flower* with large jagged leaves. 21. The narrow-leaved *ſun-flower* with jagged leaves. 22. The New England *ſun-flower* with very large trifid leaves. *Tourn.* Inſt. p. 489.

There are ſeveral different ſpecies of this flower, all which are very beautiful in large gardens. They are moſt of them annual plants, and are to be ſown every ſpring in a bed of good light earth. When the ſhoots are about three inches high, they muſt be tranſplanted into nurſery beds, and ſet at eight inches diſtance every way; they ſhould remain here till they are a foot high, and then be carefully taken up with a ball of earth at their roots, and planted in large borders, or intermixed in the boſquets of large growing plants; they muſt be frequently watered till they have taken root, and after that will require no farther care. In July the flowers appear, and ſtand a conſiderable time: the largeſt of theſe ſhould be left to ſtand for ſeed. The birds are very apt to devour this ſeed, but it ſhould be carefully guarded from them, and the head left on the plant till October, at which time it ſhould be cut off, and hung up to dry in an airy place, and in a month more the ſeeds will be perfectly hardened.

Several ſpecies of this plant alſo are perennial, and increaſe greatly by the root. Among theſe the common ſmaller-flowered one is a very valuable plant in gardens, as it requires no culture, will grow in all ſoils and ſituations, and is a very ornamental flower, continuing in bloom from June to October. *Miller*'s Gard. Dict.

Small SUN-*flower*. See HELIANTHEMUM.

SUN-*dew*. See ROS *ſolis*.

SUN-*ſcorched*, a term uſed by our gardeners in ſome parts of England to expreſs a diſtemperature of fruit trees, owing to the *ſun*'s affecting them too forcibly and too ſuddenly; the conſequence of which is the loſs and withering of the fruit. Such trees only are ſubject to this, as are planted in places ſheltered from the ſpring *ſun*, and only open to the ſummer's; and it may be always cured by proper waterings.

Mr. Merret gives us an account of three cherry-trees, of that kind we call *May-dukes*, which he cured in this manner. Theſe trees were planted in a very rich mould, which lay to a ſouth wall, ſhaded four months of the winter from the *ſun* by a high building, ſo that the *ſun* never came upon them till the latter end of March; when being high, and ſhining ſomewhat fiercely upon them, from that time the fruit had been always uſed to wither. In a very hot ſummer, when theſe trees ſeemed going into a worſe way than ordinary, the roots of one of them was bared, and a hole being made about it, a gallon of water was poured into it every morning and evening for about a fortnight before the cherries came to a redneſs.

The effect of this was, that the fruit was full and good, while the two trees that ſtood next it had their fruit withered and ſcorched up. One of theſe was taken into conſideration more late, and being watered from time to time, thoſe fruits which were moſt withered on it fell off, and the reſt grew ripe of themſelves, and proved very good ones. The third tree, which was left to itſelf, produced not one ripe good cherry. Phil. Tranſ. N° 23.

SUNCOPULLY, in natural hiſtory, a name given by the people of the Eaſt-Indies to a kind of ſparry ſubſtance of a whitiſh colour, which they calcine, and afterwards give in agues, and other intermittent caſes.

It is erroneouſly by ſome ſuppoſed to be a ſpecies of arſenic; for it has none of its qualities.

SUONATA, in muſic. See SONATA, *Cycl.*

SUONATINA, or SONATINA, in the Italian muſic, a little, ſhort, eaſy *ſonata*. See SONATA, *Cycl.*

SUPERBUS *muſculus*, a name given by ſome to the elevator oculi, or the muſcle whoſe office is to raiſe and lift up the eye; that motion giving a haughty look.

The *ſuperbus muſculus* is one of the muſcles called by Albinus the *quatuor recti oculi*. See ATOLLENS.

SUPERFICIAL (*Cycl.*)—SUPERFICIAL *fourneau*, in fortification, the ſame with *caiſſon*, which is a wooden cheſt, or box, with three, four, five, or ſix bombs in it. Sometimes it is filled only with powder, and uſed in ſieges, by being buried under ground, with a train to it, to blow up any lodgment that the enemy may make.

SUPERFICIALIS *ſphincter*, in anatomy, a name given by Riolanus, and ſome others, to the muſcle of the anus, called by Winſlow and Albinus *ſphincter internus ani*. This author, and ſome others, call it alſo *ſphincter cutaneus*.

SUPERFICIES (*Cycl.*)—*Internal* SUPERFICIES *of the earth*, a term uſed by Tull, and others, to expreſs that part of the earth which affords the pabulum, or what is called the *paſture of plants*.

Plants themſelves are the paſture of animals; but it is from this *internal ſuperficies of the earth* that vegetables firſt receive the nouriſhment which they afterwards give to animals. This inner *ſuperficies of the earth* is the *ſuperficies* of the pores, cavities, and interſtices of the divided parts of the earth; and theſe are of two kinds, natural and artificial. Tull is the firſt who has uſed this term, and he juſtifies himſelf from the imputation of having uſed an abſurd phraſe, as it might at firſt ſeem, the adjective expreſſing ſomething within, and the ſubſtantive ſomething without, by obſerving, that though the vegetable paſture is within the earth, yet it is alſo on the outſides of the divided parts of the earth.

Of the natural and artificial paſture of plants, or the natural and artificial cavities, pores, and interſtices of the earth, the natural alone will ſuffice to furniſh a country with vegetables for the maintenance of a few inhabitants: but if the artificial, that is, if agriculture, the ſole buſineſs of which is the making this artificial paſture for plants, were aboliſhed out of the world, it is much to be feared, that the people of all populous countries, eſpecially of thoſe toward the borders of the frigid zones, (for there the trees often fail of producing fruit) would be reduced to the utmoſt neceſſities for want of this proper kind of food.

The artificial paſture of plants is that inner *ſuperficies* of the earth, which is made by dividing the ſoil by art. This, on all parts of the globe where it is uſed, maintains many more people

people than the natural one; in the colder countries it maintains ten times as many as the natural one, and when the art of agriculture is more advanced to perfection, it will maintain twice as many as it does at present; and this improvement is eaſy, and to be done by ſimple means.

The natural paſture is not only leſs than the artificial, in an equal quantity of ground; but the little there is of it conſiſting alſo of the *ſuperficies* of pores and cavities not having a free communication with one another, they are leſs pervious to the fine roots of all vegetables, which require a greater force to break through their partitions; and by that means roots, eſpecially of weak plants, are excluded from many of thoſe cavities; ſo that the benefit of a great part of the paſture that really is there, is loſt to the huſbandman.

The artificial paſture, on the other hand, conſiſts in *ſuperficies* of cavities that are pervious to all roots, and give them free paſſage throughout the whole extent of the cultivated place; and conſequently, the fine horizontal roots of plants, which run much farther than is generally ſuppoſed, (thoſe of a turnep, for inſtance, running ſix feet diſtant from the main root every way; ſee ROOT) will find an eaſy paſſage in every part to the utmoſt extent to which nature allows them to run.

The *internal ſuperficies of the earth*, which is the paſture of plants, is not like the external ſurface, which is the paſture of animals, in that it cannot be inlarged without the addition of more ſurface taken from land adjoining to it, by inlarging its bounds or limits: but the *internal ſuperficies*, or artificial paſture of land, may be inlarged without addition, or more land, only by diviſion of the ſame earth: and this artificial paſture may be increaſed in proportion to the diviſion of the parts of the earth, whereof it is the *ſuperficies*.

A cube of earth of one foot has but ſix ſquare feet of *ſuperficies*; but divide this cube into cubical inches, and then its *ſuperficies* will be increaſed twelve times, that is, it will be ſeventy two *ſuperficial* feet. Divide theſe cubes again into ſuch others, as bear the ſame proportion to an inch that an inch does to a foot, and then the ſame quantity of earth, which had at firſt only ſix feet *ſuperficies*, will have a *ſuperficies* of eight hundred and ſixty four feet of natural paſture: and in the ſame manner is the ſoil diviſible, and conſequently this paſture increaſable *ad infinitum*.

Poor land does not afford an *internal ſuperficies* ſo well ſtocked with theſe fruitful particles as rich land does, but this we may compenſate by dividing it more, and then what it wants in quality may be made up in quantity.

The common method of dividing the ſoil is by dung, or by tillage, or by both; and none of the natural paſture is ever loſt, or injured by the uſe of the artificial means, but, on the contrary, it is mended by ſuch means, a free communication being made by them between pore and pore. *Tull's* Horſehoeing Huſbandry, p. 18.

SUPERFLUOUS *interval*, in muſic, is one that exceeds a true diatonic interval by a ſemitone minor. Thus the

SUPERFLUOUS *ſecond*, or *tone*, contains a ſemitone minor more than a tone, or greater ſecond; and will therefore be expreſſed by $\frac{125}{108}$, or by $\frac{75}{64}$. The firſt of theſe expreſſions is a tone minor, and a ſemitone minor; ſince $\frac{10}{9} \times \frac{25}{24} = \frac{125}{108}$: and the other is a tone major, and ſemitone minor; for $\frac{9}{8} \times \frac{25}{24} = \frac{75}{64}$. This laſt occurs in practice, and is one of the intervals of the chromaticum toniæum. See the article CHROMATIC.

In temperate ſcales theſe two *ſuperfluous* tones coincide. Thus from B b to C ſharp, or from F to G ſharp, are *ſuperfluous* tones.

SUPERFLUOUS *third* is greater than the third major by a ſemitone minor, and will therefore be expreſſed by $\frac{125}{96} = \frac{5}{4} \times \frac{25}{24}$. It is not in uſe. It ſeems a fourth on our harpſichords. Thus from B b to D ſharp is, properly ſpeaking, a *ſuperfluous third*; but D ſharp and E b being confounded, it paſſes for a fourth.

SUPERFLUOUS *fourth*. This interval is expreſſed by $\frac{25}{18} = \frac{4}{3} \times \frac{25}{24}$. It is by practitioners, and in temperate ſcales, confounded with the tritonus. See INTERVAL.

SUPERFLUOUS *fifth* is expreſſed by $\frac{25}{16} = \frac{3}{2} \times \frac{25}{24}$. This is equal to two thirds major, for $\frac{5}{4} \times \frac{5}{4} = \frac{25}{16}$. The *ſuperfluous fifth* occurs in practice, as from C to G ſharp.

SUPERFLUOUS *ſixth*. This interval is of two kinds; being the reſpective complements of the two diminiſhed thirds to the octave. One only, ſtrictly ſpeaking, anſwers to the general definition of a *ſuperfluous* interval, which is that interval which exceeds the ſixth major by a ſemitone minor, and is therefore expreſſed by $\frac{125}{72} = \frac{5}{3} \times \frac{25}{24}$. But the other interval, which is a comma more than the former, and is two ſemitones major leſs than the octave, is chiefly uſed in harmony, as between B b and *a* ſharp, where it has a fine effect. It is expreſſed by $\frac{225}{128} = \frac{2}{1} : \frac{16}{15} : \frac{16}{15} = \frac{2}{1} : \frac{256}{225}$. See the articles INTERVAL and DIMINISHED *third*.

SUPERFLUOUS *ſeventh* is expreſſed by $\frac{15}{8} \times \frac{25}{24} = \frac{125}{64}$. This is a dieſis leſs than the octave. See INTERVAL.

SUPERFLUOUS *octave* is a ſemitone minor more than the octave, as from C to *c* ſharp. It ſometimes occurs in the baſſes of inſtrumental pieces.

SUPERGEMINANS, a name given by ſome anatomical writers to the epididymis.

SUPERGENUALIS, a name given by ſome authors to the patella, or knee pan. See PATELLA.

SUPERIOR (*Cycl.*)—SUPERIOR *auriculæ muſculus*, in anatomy, a name given by Santorini, and by Winſlow, to one of the muſcles of the ear, called by Albinus and Cowper the *attollens auriculam*, and by many *auriculæ primus*.

SUPERIOR *courts of record*. See the article COURT.

SUPERNUMERARII, in the later times of the Roman empire, ſoldiers added to the legion after it was completed. They were the ſame with thoſe in former times, called *accenſi*. *Pitiſc.* in voc. See ACCENSI, *Cycl.* and *Suppl.*

SUPERNUMERARY (*Cycl.*)—SUPERNUMERARY *bones of the head*. Anatomiſts diſtinguiſh by this appellation ſeveral bony pieces found in ſome ſkulls, chiefly between the parietal and occipital bones. They form breaks in the lambdoidal ſuture, and are joined by true ſutures to the bones already mentioned.

Their figure, number, and ſize vary extremely; ſometimes they are triangular, or approaching to that form, but oftener they are of no determinate figure: in ſome ſubjects they incroach on the occipital bone, and in others on the parietal bones; and ſometimes they extend themſelves every way. They are commonly indented, and broader on the outſide of the ſkull than on the inſide, in which they have no viſible indentations; and ſometimes, when they are ſmall on the outſide, are hardly at all to be ſeen within. They have by ſome been termed keys, a name uſed by joiners for the pieces which ſerve to ſtrengthen the joints of boards; but this can agree to them only in reſpect to their ſituation, not in reſpect to their uſes with regard to the other bones of the head. Some ſuch bones have alſo been found in the joints, between the bones of the head and face; and between thoſe of the bones of the face with each other. *Winſlow's* Anatomy, p. 53.

SUPERONERATIONE *paſturæ*, a judicial writ, that lies againſt him who is impleaded in the county court for the ſurcharging, or overburthening a common with his cattle, in a caſe where he was formerly impleaded for it in the ſame court, and the cauſe is removed into one of the courts at Weſtminſter. Reg. Judic. *Blount*, *Cowel*.

SUPERPARTICULAR (*Cycl.*)—SUPERPARTICULAR *ratio*. Ptolemy, in his Harmonics, ſeems to lay a great ſtreſs on *ſuperparticular ratios* [c], beyond the ſuperpartient in muſic. He does not call the intervals which may be expreſſed by the former ratios, excepting 2 : 3 and 3 : 4, diſſonants, as the Pythagoreans did, but concinnous, as if they were of a middle nature between conſonant and diſſonant. But all this doctrine of *ſuperparticular ratios* is a precarious hypotheſis. The two thirds, major and minor, expreſſed by 5 : 4 and 6 : 5, are *ſuperparticular*, and concords. Their octaves, 5 : 2 and 12 : 5, are *ſuperparticular*, and concords alſo. Ptolemy himſelf refutes the Pythagoreans for excluding the diapaſon diateſſaron, expreſſed by 8 : 3, from the number of concords, becauſe its proportions were ſuperpartient; yet his own doctrine is equally precarious [d].—[[c] See RATIO, *Cycl.* [d] Vid. *Euler*, Tentam. Nov. Theor. Muſic. p. 63, 64.]

SUPER-PRÆROGATIVA *regis*, a writ which formerly lay againſt the king's widow for marrying without the ſucceſſor's licence. F. N. B. 173. *Blount*, *Cowel*.

SUPER-STATUTO *de articulis cleri cap.* 6. a writ lying againſt the ſheriff, or other officer, that diſtrains in the king's highway, or in the lands antiently belonging to the church. F. N. B. 173. *Blount*, *Cowel*.

SUPER-STATUTO *facto pour ſeneſchal & marſhal de roy, &c.* a writ that lies againſt the ſteward or marſhal for holding plea in his court, or for treſpaſs or contracts not made, and ariſing within the king's houſhold. F. N. B. 141. *Blount*, *Cowel*.

SUPER-STATUTO *verſus ſervantes & laboratores*, a writ which lies againſt him who keeps any ſervants departed out of the ſervice of another contrary to law. F. N. B. 167. *Blount*, *Cowel*.

SUPINATOR (*Cycl.*)—SUPINATOR *brevis*, in anatomy. This is a ſmall thin fleſhy muſcle, ſurrounding a great portion of the upper part of the radius.

It is fixed by one end to the lower part of the external condyle of the os humeri, to the external lateral ligament of the joint, to the annular ligament of the radius, and to part of the lateral eminence in the head of the ulna; from thence it paſſes obliquely over the head of the radius, covering ſome part of it, and running down upon, and in ſome meaſure ſurrounding the neck, it turns in under the occipital tuberoſity, and is inſerted by the ſide of the interoſſeous ligament, in the inſide of the ſuperior quarter of the bone, and even a little lower. In ſome ſubjects we may obſerve the marks of the paſſage of this muſcle over the outſide of the bone. It makes an angle with the pronator teres, reſembling the Roman V. *Winſlow's* Anatomy, p. 190.

SUPINATOR

SUPINATOR *longus*, a long flat muscle, lying on the external condyle of the os humeri, and on the convex side of the radius, from one end to the other.

It is fixed by fleshy fibres to the external intermuscular ligament, and to the crista of the external condyle of the os humeri, for five or six fingers breadth above the condyle, between the brachiæus, and anconæus externus; from thence it runs along the whole convex side of the radius, and is inserted by a flat narrow tendon, a little above the styloide apophysis, in the angle between the concave and flat sides of the extremity of this bone. *Winslow*'s Anatomy, p. 189.

SUPPLE. To *supple* a horse, in the manege, is to make him bend his neck, shoulders, and sides, and to render all the parts of his body more pliable.

SUPPOPLITÆUS, in anatomy, a name given by Spigelius, and some others, to the muscle more generally known by the name of the *poplitæus*. See POPLITÆUS.

SUPPRESSION (*Cycl.*)—SUPPRESSION *of urine*. There are commemorated, in the Philosophical Transactions, three cases of an actual and total *suppression of urine*, supposed to proceed from a stone lodged in the neck of the bladder; but in all which, on introducing the catheter, it was found that there was no stone there, nor any urine in the bladder. In all these cases the same remedy was used; that is, a great quantity of acids diluted largely with water, and in consequence of this the urinary secretion was immediately restored, and the patient soon voided it in a proper manner, and was restored to health without any further use of medicines. Philos. Trans. N° 253.

A *suppression of urine* sometimes happens to women with child, by the womb falling down, and pressing on the urethra. See Act. Acad. Nat. Curios. Not. 4. Obs. 113.

SUPPRESSIONIS *ignis*, a *fire of suppression*, a term used in chemistry to express such an application of fire to any subject, that it shall at once act upon it above and below in the same manner. The usual way of giving this heat, is by covering the vessel, in which the ingredients are put, with sand, and then laying hot coals upon that, so that they may heat through the sand downwards.

SUPPURATION (*Cycl.*)—When in tumors and phlegmons nature shews a tendency to *suppuration*, or ripening, all the resolving, or dispersing medicines must be laid aside, and great care must be taken to forward the maturity of the inflammation, that is, to convert the stagnating blood into laudable matter; then to give a discharge, or vent, to this *suppurated* matter, afterwards to cleanse the part, and finally to incarn, and heal it.

The first of these intentions, the ripening the swelling, is to be promoted by such of the emollient medicines as obstruct the pores of the skin, as fats, oils, and glutinous medicines; as also the sharp, pungent, and, in some degree, caustic medicines, which may be used in form of cataplasms, or plasters. Of the first kind are mallows, marshmallows, figs, linseed, honey, crumb of bread, the various animal fats, and the oils of lillies, chamæmile, &c. and of the latter, or the sharp and pungent ripeners, are garlic, onions, saffron, turpentine, and many of the gums, as galbanum and ammoniacum; and lastly, sour leven of bread.

Medicines compounded of these are to be applied hot to the part, and the application frequently repeated, till the matter within is found to be sufficiently ripened, by the softness and whiteness of the tumor. But when the abscess is small, it is more convenient, and sufficient, to apply some of the ripening plasters, as diachylon, with the gums, or the like, till the *suppuration* is perfected.

Nor are internal remedies wholly to be neglected in cases of this kind, especially where the tumors are large, or of consequence. In these cases, when the blood moves too slowly, which may be known by the pulse, the patient must be allowed to eat meat, and must take such medicines as are warm and stimulating; by means of which, and by the increased motion of the blood, the inspissated particles contained in the smaller vessels will be the more easily converted into matter.

Strong broths are very proper for this purpose, as also the use of wine, or ale, in moderation; and Venice treacle, diascordium, and the confection of alkermes, are to be the medicines taken three or four times a day, and medicated teas, made of sanders-wood, sassafras, or cinnamon. But, on the contrary, when the motion of the blood is too violent, and the heat too great, cooling medicines are to be given, such as the thin and watery drinks, the subacid medicines, and nitre: bleeding, in a small quantity, is also often necessary in this case. But when the constitution is sound, and the blood's motion regular, the use of internal medicines, to promote *suppuration*, is trifling, and may be altogether rejected. When by these means the matter is perfectly formed, the abscess is to be carefully opened by the surgeon, and the matter discharged, after which the wound is to be cleansed and healed in the common way. *Heister*'s Surgery, p. 183.

SUPRACOSTALES, muscles irregularly triangular, and situated on the back part of the ribs, near the vertebræ, commonly called *levatores costarum*.

Each of these is fixed by one tendinous extremity in the transverse apophysis, which lies above the articulation of each rib, and to the neighbouring ligament; the first being inserted in the transverse apophysis of the last vertebra of the neck, and the last in that of the eleventh vertebra of the back. From thence the fleshy fibres run down obliquely, increasing in breadth as they descend, and are inserted in the back part of the outside of the following rib; some of the fibres often pass beyond that rib, and are fixed in one or more of the ribs below it by several digitations, which lie at a greater distance from the vertebræ, in proportion as they run lower. In the inferior ribs these digitations are more considerable than in the superior. *Winslow*'s Anatomy, p. 232.

SUPRACOSTALES *longi*, in anatomy, a name given by Verheyen to those muscles of the loins, which Albinus has described under the names of the *levatores longi costarum*. See the article LEVATORES.

SUPRASPINATUS, in anatomy, is a thick narrow muscle, in some measure penniform, filling all the *supra-spinal* cavity of the scapula.

It is fixed to all the posterior half of the *supra-spinal* fossa, and sometimes its insertion reaches near the neck of the bone. Then the fibres leave the surface of the bone, and being, as it were, supported by the fat, or cellulous substance, pass between the acromium, and neck of the scapula, under the arch formed by the acromium and extremity of the clavicle, and under the ligament between the acromium and apophysis coracoides; being afterwards inserted in the superior surface of the great tuberosity of the head of the os humeri, very near the bony channel. This muscle is covered by the trapezius. *Winslow*'s Anatomy, p. 184.

SUPREME *pear*, a name given by the gardners to a small pear, called also by some the *little musk pear*. It is of a roundish shape, and is usually produced in clusters. The stalk is short, and when it is ripe, the skin is yellow. The juice is somewhat musky. If it be not suffered to hang till too ripe, it is an excellent pear. It ripens in the beginning of July, and continues good but a few days. The French call it *le petit muscat*. *Miller*'s Gard. Dict.

SURA, (*Cycl.*) the name of a drink used in the East-Indies, and made of the juice that flows from the cocoa-tree. *Boyle*'s Works Abr. p. 51.

This juice being evaporated, and exposed to the sun, forms a sugar, but it is little esteemed. *Boyle*, ibid. p. 53.

SUR CUI *in vita*, in law, a writ that lies for the heir of a woman, whose husband aliened her land in fee, and she neglected to bring the writ *cui in vita* for recovery thereof, her heir may bring this writ against the tenant after her decease. F. N. B. 193. Terms of Law. *Blount*, *Cowel*.

SURCULUS, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf which is of a middle kind, between the great middle rib and the smallest reticular ramifications. The middle rib is, by the writers on these subjects, called *petiolum*.

The first divisions, that go off laterally from these, are called *rami*, or branches; the next division of these, into more minute ones, are called *surculi*; and the final divarications of these into the reticular work, that spreads itself over the whole leaf, are called *capillamenta*.

Many, however, confound these two last divisions, and call all beyond the second division, or lateral branches of the middle rib, by this name of *surculi*. Act. Erudit. 1722. See PETIOLUM and RAMUS.

SURD (*Cycl.*)—Simple *surds* are commensurable in power, and by being multiplied into themselves give, at length, rational quantities. But compound *surds*, multiplied into themselves, commonly give irrational products. Yet in this case, when any compound *surd* is proposed, there is another compound *surd*, which multiplied into it, gives a rational product. Thus if $\sqrt[3]{a}-\sqrt[3]{b}$ were proposed, multiplying it by $\sqrt[3]{a^2}+\sqrt[3]{ab}+\sqrt[3]{b^2}$, the product will be $a-b$.

The investigation of that *surd*, which multiplied into the proposed *surd*, gives a rational product, is made easy by three theorems, delivered by Mr. Maclaurin, in his Algebra, p. 109, seq. to which we refer the curious.

This operation is of use in reducing *surd* expressions to more simple forms. Thus suppose a binomial *surd* divided by another, as $\sqrt{20}+\sqrt{12}$ by $\sqrt{5}-\sqrt{3}$, the quotient might be expressed by $\frac{\sqrt{20}+\sqrt{12}}{\sqrt{5}-\sqrt{3}}$. But this might be expressed in a more simple form, by multiplying both numerator and denominator by that *surd*, which multiplied into the denominator, gives a rational product: thus,

$$\frac{\sqrt{20}+\sqrt{12}}{\sqrt{5}-\sqrt{3}}=\frac{\sqrt{20}+\sqrt{12}}{\sqrt{5}-\sqrt{3}}\times\frac{\sqrt{5}+\sqrt{3}}{\sqrt{5}+\sqrt{3}}=\frac{\sqrt{100}+2\sqrt{60}+6}{5-3}=\frac{16+2\sqrt{60}}{2}=8+2\sqrt{15}.$$

To do this generally, see Mac Laurin, lib. cit. p. 113.

When the ſquare root of a *ſurd* is required, it may be found, nearly, by extracting the root of a rational quantity that approximates to its value. Thus, to find the ſquare root of $\surd\overline{3+2\surd 2}$, firſt calculate $\surd 2 = 1,41421$. Hence, $3+2\surd 2 = 5,82842$, the root of which is found to be nearly 2,41421.

In like manner we may proceed with any other propoſed root. And if the index of the root, propoſed to be extracted, be great, a table of logarithms may be uſed.

Thus $\sqrt[7]{5+\sqrt[13]{17}}$ may be moſt conveniently found by logarithms.

Take the logarithm of 17, divide it by 13; find the number correſponding to the quotient; add this number to 5; find the logarithm of the ſum, and divide it by 7, and the number correſponding to this quotient will be nearly equal to $\sqrt[7]{5+\sqrt[13]{17}}$.

But it is ſometimes requiſite to expreſs the roots of *ſurds* exactly by other *ſurds*. Thus, in the firſt example, the ſquare root of $3+2\surd 2$ is $1+\surd 2$: for $\overline{1+\surd 2} \times \overline{1+\surd 2} = 1+2\surd 2+2 = 3+2\surd 2$.

For the method of performing this, the curious may conſult Mr. Mac Laurin's Algebra, p. 115, ſeq. where alſo rules for trinomials, &c. may be found.

For extracting the higher roots of a binomial, whoſe two members being ſquared are commenſurable numbers, we have a rule in Sir Iſaac Newton's *Arithmetica Univerſalis*, p. 59, but without demonſtration. This is ſupplied by Mr. Mac Laurin, in his Algebra, p. 120, ſeq. as alſo by 'sGraveſande, in his *Matheſeos Univerſalis Element.* p. 211, ſeq.

It ſometimes happens, in the reſolution of cubic equations, that binomials of this form $a \pm b\surd -9$ occur, the cube roots of which muſt be found. To theſe Sir Iſaac's rule cannot always be applied, becauſe of the imaginary, or impoſſible factor $\surd -9$; yet, if the root be expreſſible in rational numbers, the rule will often lead to it in a ſhort way, not merely tentative, the trials being confined to known limits. See *Mac Laur.* loc. cit. p. 127, ſeq.

It may be farther obſerved, that ſuch roots, whether expreſſible in rational numbers, or not, may be found by evolving the binomial $a+b\surd -9$ by the Newtonian theorem, and ſumming up the alternate terms. *Mac Laur.* loc. cit. p. 130.

Thoſe who are deſirous of a general and elegant ſolution of the problem, *to extract any root of an impoſſible binomial* $a+\surd -b$, *or of a poſſible binomial* $a+\surd b$, may have recourſe to Mr. De Moivre's Letter to Dr. Saunderſon, inſerted by way of Appendix to his Algebra, p. 744, ſeq. and to the Philoſophical Tranſactions, N° 451. or to Dr. Martyn's Abridgment, Vol. 8. p. 1, ſeq.

SURFACE (*Cycl.*)—A *ſurface* is not a body of the leaſt ſenſible magnitude, as ſome have imagined, but it is the termination, or boundary of a body; neither is a line to be conſidered as a *ſurface* of the leaſt ſenſible breadth, but as a termination, or limit of a *ſurface*: nor is a point to be conſidered as the leaſt ſenſible line, but as the termination of a line; and in this ſenſe it is plain that a point cannot be conceived to have parts, or magnitude. See MAGNITUDE. See alſo *Mac Laurin*'s Fluxions, Vol. 1. p. 245. and Mr. *John Bernoulli*'s Letter to Monſieur Crouzas, concerning his Comment on the Analyſe des Infiniment petits. *Jo. Bernoul.* Oper. Vol. 4. p. 160, ſeq.

SURF *of the ſea*, the great breakings, or rolling of the ſea againſt ſome ſhores; making it dangerous to land in ſuch places.

SURMULLET, in zoology, a name uſed, both by the French and Engliſh, for the *mullus major*, a fiſh of the cuculus kind, in many things reſembling the mullus barbatus, but differing from it in that it is twice as big, being often caught of twelve or fourteen inches in length. Its fins alſo are yellowiſh, and have a ſlight bluſh of red mixed with that colour. Its ſcales are large and broad, and thick, and are more firmly joined to the fleſh. It has alſo three or four ſtrait yellow lines, running parallel with one another down its ſides. It is caught in the Mediterranean, and in the Britiſh ſeas, eſpecially on the coaſt of Cornwall, and is every where eſteemed a very delicate fiſh. *Ray*'s Ichthyography, p. 285.

SURO, in zoology, a name given by ſome to a fiſh of the cuculus kind, much reſembling the mackrel in taſte and in ſhape, and more uſually known by the name of the *trachurus*. *Willughby*'s Hiſt. Piſc. p. 290. See TRACHURUS.

SURRECTORIUM, the name of a chirurgical inſtrument, mentioned by Ambroſe Parè, and intended to keep the arm in an erect ſituation when required.

SURVEYING (*Cycl.*)—A *ſurveyor* ought to be provided with an off-ſet ſtaff, equal in length to ten links of the chain [b], and divided into ten equal parts. He ought likewiſe to have ten arrows, or ſmall ſtrait ſticks, near two feet long, ſhod with iron ferrils. When the chain is firſt opened, it ought to be examined by the off-ſet ſtaff. In meaſuring any line, the leader of the chain is to have ten arrows at firſt ſetting out. When the chain is ſtretched in the line, and the near end touches the place from which you meaſure, the leader ſticks one of the ten arrows in the ground at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being ſtretched in the line, ſo that the near end touches the firſt arrow, the leader ſticks down another arrow at his end of the chain. The line is preſerved ſtrait, if the arrows be always ſet ſo, as to be in a right line with the place you meaſure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain the arrows are to be carried to him again, and he is to ſtick one of them in the ground, at the end of the chain: and the ſame is to be done at the 21, 31, 41, &c. chains, if there are ſo many in the right line to be meaſured. In this manner an error can hardly be committed in numbring the chains, unleſs of ten chains at once [c].—[[b] See CHAIN. [c] Treat. Pract. Geom. p. 72, 73.]—See farther under FIELD-*book*, OFF-SETT, STAFF, and THEODOLITE.

If the lands to be plotted are hilly, and not in any one plane, the lines meaſured cannot be truly laid down on paper, without being reduced to one plane, which muſt be the horizontal, becauſe angles are taken in that plane.

In viewing objects, if they have much altitude or depreſſion, either write down the degree and decimal, ſhewn on the double ſextant, or the links ſhewn on the back ſide, which laſt ſubtracted from every chain in the ſtation line, leaves the length in the horizontal plane; but if the degree is taken, the following table will ſhew the quantity.

A TABLE *of the links to be ſubtracted out of every chain in hypothenuſal lines of ſeveral degrees altitude, or depreſſion, for reducing them to horizontal.*

degrees.	links.	degrees.	links.	degrees.	links.
4.05	$\frac{1}{4}$	14.07	3	23.074	8
5.73	$\frac{1}{2}$	16.26	4	24.495	9
7.02	$\frac{3}{4}$	18.195	5	25.84	10
8.11	1	19.95	6	27.13	11
11.48	2	21.565	7	28.36	12

Let the firſt ſtation line really meaſure 1107 links, and the angle of altitude, or depreſſion, be 19° 93′; looking in the table, I find 19° 95′ is 6 links; now 6 times 11 is 66, which ſubtracted from 1107 leaves 1041, the true length to be laid down.

It is uſeful in *ſurveying* to take the angles which the bounding lines form with the magnetic needle, in order to check the angles of the figure, and to plot them conveniently afterwards.

Large maps, repreſenting conſiderable extents of ground, are ſubject to a good many inconveniencies, eſpecially if carried into the fields, to be compared with them; ſuch maps become very troubleſome in the wind, and it is difficult to find out the part you want. To remedy this, a general and ſmall map of the manor, or county, &c. ſhould be firſt made on one ſheet of paper, the ſeveral parts may be ſet off on other ſeparate ſheets, and the general map being divided into as many ſquares as there are of theſe particular ſheets, the relation of the whole to the ſeveral parts is eaſily ſeen; and all theſe maps may then be bound up in a book. See Mr. *Baighton*'s Deſcription and Uſe of his New Plotting Table, in Phil. Tranſ. N° 461. ſect. 1.

SURVEYING-*ſcale*, the ſame with *reducing-ſcale*.

SURVEYOR (*Cycl.*)—*Surveyor* of the king's Exchange, an antient officer, mentioned in the Statute 9 Hen. V. Stat. 2. cap. 4. But what his office was is uncertain. *Cowel.*

SUS, the *hog*, in the Linnæan ſyſtem of zoology, a diſtinct genus of animals, the characters of which are; that they have uſually ten paps, ſituated along their belly; their dentes inciſores are four each way; and in the males, the canine, or dog-teeth, are extremely long. Of this genus are the *hog* kind, the Mexican muſk-boar, and the babyrouſſa. *Linnæi* Syſtem. Nat. p. 41.

SUS *piſcis*, in ichthyology, a name given by Ovid, and ſome other of the antient writers, to the fiſh called alſo *us* and *mus*, and by the later writers *capriſcus*. See the article CAPRISCUS.

SUS *agreſtis*, the *wild boar*. This creature differs from the common domeſtic *hog*, in that the grown animal is not different in colour in the different individuals of the ſame ſpecies, but is always of a ruſty iron grey. His ſnout is much longer alſo than that of the other; his ears ſhorter and rounder; and both theſe, and his tail and feet, are always black. It differs alſo, in that it is covered with two ſorts of hairs, the one kind long, the other ſhort: theſe laſt ſerve the creature to the ſame purpoſes, as the downy fur which the bever and otter have under their long hair. It is very common wild in Italy, and its fleſh frequently brought to market. *Ray*'s Syn. Quad. p. 96.

SUSCEPTOR, among the Romans, a citizen choſen by the decuriones to collect the debts belonging to the public. *Pitiſc.* in voc.

SUSCEPTOR is alſo a term uſed by eccleſiaſtical writers for *ſponſor*. See SPONSOR, *Cycl.*

SUSCEPTOR *aurarius*, in middle age writers. See the article AURARIA.

SUSPENSORIUS, in anatomy, a muſcle of the eye. It is ſo called, from its uſe in ſuch animals as go much with their head hanging down. Veſalius has deſcribed it as belonging to man, in whom it is never found. Fiſhes and fowls are commonly without it, as well as man; but oxen, and, ſo far as has been obſerved, all quadrupeds, are provided therewith; though it is not of the ſame ſtructure in all. Dr. *Porterfield*, in Med. Eſſ. Edinb. Vol. 3. Art. 12.

The doctor thinks, that the uſe of this muſcle is not only to ſuſpend the eye, and preſerve the optic nerve from being too much ſtretched, but principally to aſſiſt the ſtreight muſcles in moving the eye, according as its different fibres act.

SUSSEX *marble*, a name given by many to a peculiar ſpecies of marble found in the county, the name of which it bears, and formerly much uſed in the pillars of churches, and other buildings, but now leſs regarded. The ground of this *marble* is grey, with a faint caſt of green, and it is very thick ſet in all parts with ſhells; theſe are chiefly of the turbinated kind, and they are generally filled with a white ſpar, which adds very greatly to the beauty of the ſtone.

It is plain, from conſidering the whole maſs of this *marble*, that this ſpar was received into the ſhells before they were depoſited in the *marble*. This is about the hardneſs of the common white Genoeſe marble, if any thing, ſomewhat more hard. The ſlender round ſcapi of the pillars in Weſtminſter-Abbey, and in many other of our old Gothic buildings, are made of this kind of *marble*. Some people have thought that the ſcapi of pillars of this kind, which occur in moſt of our Gothic buildings, are artificial, and that they are a kind of fuſile marble caſt in cylindric moulds. But any one who will compare the marble, of which thoſe pillars are made, with its ſhells, and the ſpar they are filled with, with the marble of the *Suſſex* quarries, will find both to be the ſame in every particular. *Woodward*'s Cat. of Foſſ. p. 20.

SUTORIUS, in anatomy, a name given by Riolanus to a muſcle of the leg, called by Cowper, Albinus, and others, the *ſartorius*. The French authors call it the *couturier*; Veſalius, and others of the more early anatomical writers, have called it the *primus tibiam moventium*.

SUTURE (*Cycl.*)—All wounds are not to be united by the needle, but thoſe only that are oblique, tranſverſe, or angular, and at the ſame time very large and deep; or in caſes where a part is very nearly cut off; or if a wound is ſo circumſtanced, that it cannot be kept in a proper ſituation by plaſters and bandages. Wounds that are to be ſtitched, ſhould be in their recent ſtate, and muſt be firſt well cleanſed from extravaſated blood, and all extraneous bodies; there ſhould alſo be no loſs of ſubſtance, except in thoſe fleſhy parts that are eaſily elongated; and no contuſion, nor any ſign of inflammation.

Dry SUTURE. This is to be uſed in ſlight wounds, and eſpecially when they happen in the face; and indeed, wherever it may appear of force enough to keep the lips of the wound together; and as it gives no freſh pain, and occaſions no ſcar, it is much fitter for wounds of the face than the needle. The plaſters, which are to form the *dry ſuture*, ſhould be of a ſufficient length, and ſhaped like the part to which they are to be applied, ſo as to ſurround the greateſt part of it, but not the whole, leſt they ſhould retard the circulation of the blood, and bring on tumors, and miſchiefs of that kind: they muſt alſo be ſuch as will ſtick very faſt, the diachylon, if good, or the common ſticking plaſter, are fitteſt for this purpoſe. The hæmorrhage being well ſtopt, and the wound well cleanſed, ſome vulnerary balſam of the gummy kind, as the balſam of Peru, or the like, is to be applied; and over all a ſticking plaſter is to be laid, adapted to the ſize of the part. Two or more of theſe may be applied, as occaſion ſhall require, leaving a ſpace between, and they are to be ſecured in their place by the application of proper bolſters and bandages.

Petit's method of making the *ſuture* of this kind, is by letting the plaſters have one, two, or more openings in the middle, through which the ſurgeon may diſcover, as by the ſpaces left between in the former method, whether the lips of the wound are properly united or not; and may alſo be able to apply proper remedies to the part, without removing the plaſters. Theſe plaſters are applied in the ſame manner as the former, and left on till the work is compleated.

But there is alſo yet another manner of performing the *dry ſuture*, to wit; ſpread two plaſters upon ſtrong cloth, anſwering in ſize to the wound; to the ſides or margins of theſe faſten three or four tape ſtrings, according to the length of the wound, and then, after warming the plaſters, apply them on each ſide of the wound, at about a finger's breadth from it; after this bring the lips of the wound together, dreſs it as in the former method, and while an aſſiſtant keeps the lips of the wound together in a proper ſituation, tie the ends of the tapes, firſt in a ſingle, and afterwards in a ſlip knot, to keep the part in contact; over each of theſe ſhould be laid an oblong compreſs, and over all a large ſquare one, and the whole kept on by a proper bandage. The day following the wound is to be again examined, and if the tapes are looſened, they muſt be drawn tighter again; but if they are not looſened, let them remain untouched, and only moiſten the parts with a few drops of balſam, and cover them up again with the compreſſes and bandages, as before. Some, inſtead of the tape, uſe claſps of braſs, or ſteel; but this method is much leſs convenient than the former, and therefore is little uſed. *Heiſter*'s Surgery, p. 37.

Bloody SUTURE. In large wounds, eſpecially tranſverſe ones, as their lips cannot be kept in their ſituation by means of the dry *ſuture*, which is frequently the caſe in wounds of the thigh, or in the abdomen, nates, or arms; or when pieces hang from the wounded part, as often happens in wounds of the forehead, cheeks, noſe, or ears; or when wounds are large, and made in an angular, or cruciform manner, the needle muſt be uſed to bring their lips together; and this is called the *bloody*, or the *true ſuture*. This operation is alſo diſtinguiſhed into two kinds, the ſimple, and compound.

The ſimple *ſuture* is that which is performed only by the aſſiſtance of the needle and thread: to this claſs belong the interrupted *ſuture*, the glover's *ſuture*, and the twiſted *ſuture*; the laſt of theſe is ſeldom uſed but in caſes of the hare-lip, and the ſecond only in wounds of the inteſtines; but the firſt is in common uſe for all wounds which require the true, or *bloody ſuture*.

The beſt method of making the common, or interrupted *ſuture*, is this. Take a double thread, well waxed, paſs it through a ſtrong crooked needle; when the lips of the wound are brought together, and held firmly in their proper ſituation by an aſſiſtant, with one ſtroke pierce through them both, paſſing the needle through the lower lip from without inwards almoſt to the bottom, and ſo on from within outwards, obſerving to make the punctures at a finger's breadth diſtance from the wound, which in this caſe we will ſuppoſe to be in length two fingers, varying this diſtance according to the ſize of the wound. After taking off the needle, tie the ends of the thread firſt in a ſingle knot, and then in a ſlip knot, covering all with the ſame dreſſings, as are uſed in the dry *ſuture*. But if the wound be ſo large, that one ſtitch will not be ſufficient, then two or more are to be made, according to the length of it, at about a finger's breadth diſtance one from the other. To prevent the knots from bringing on any miſchief, lay a ſmall linnen compreſs over the ſingle knot, and make the ſlip knot over that; which, if any pain or inflammation ſhould ſucceed, may be afterwards eaſily looſened at pleaſure.

This is the method to be obſerved in ſtrait, oblique, or tranſverſe wounds; but where there are angles, as in a triangular wound, you are to proceed in the ſame manner, but obſerve to let the *ſuture* begin at the angle, and the other ſtitches be taken about the middle, both ways; but if the wound be quadrangular, or have two angles, like the Greek letter Π, which ſometimes happens in the face, then the *ſutures* muſt be made in both the angles; and when the wound is ſo large, that theſe are not ſufficient, then as many more, as are neceſſary, muſt be made in the midway between them. When you meet with a cruciform wound, and the lips of it cannot be kept together by the uſe of plaſters, the *bloody ſuture* muſt be made, by paſſing the needle through the lips, near the end of each extremity of the wound; and when the ſtitches are all thus made, the threads muſt be tied as in the other caſes. *Heiſter*'s Surgery, p. 38.

Compound SUTURE. Some of the ſurgeons among the antients uſed a *compound ſuture* for large wounds, inſtead of the interrupted *ſuture*, now generally practiſed: they preferred this method, becauſe it prevented the lips of the wound from being lacerated, which ſometimes happened when the other method was uſed, and not only prevented the wound from uniting, but frequently brought on other grievous diſorders; and though this method has of late years been rejected, and particularly by Dionis, in his Surgery, yet many ſtill prefer it, in ſeveral caſes, to the common interrupted *ſuture*: but inſtead of the pieces of wood uſed by the antients, thoſe, who now practiſe it, uſe pieces of plaſter rolled up in a cylindrical form, of the length of the wound, and of about the ſize of a gooſe-quill, from whence it is called by ſome the *quilled ſuture*. This method prevents tumors, pain, and inflammations, which might be brought on by the hardneſs and preſſure of wood.

Palfynus performs this operation, in deep wounds of the muſcular parts, with a large and ſtrong crooked needle, furniſhed with a double thread well waxed, which has alſo a bow at one end. The needle thus fitted being paſſed thro' both lips of the wound, in the ſame manner as in the other operations of the true *ſuture*, and afterwards a ſecond, and a third, paſſed in the ſame manner, a roll of plaſter is to be introduced into the bow ends of the thread, which are left hanging out; then when the needle is taken out at the other ſide, another roll of plaſter is to be placed between the ends of the thread; and the lips of the wound being brough

brought together, these ends are to be gently tied over the roll, first in a single, and then in a slip knot. If there are three of these threads, you are to tie the middle one first, and afterwards the rest in the same manner. On the first days after the operation of the *suture* is performed, in whatever method that be done, the bandage and compress are to be gently removed, and the state of the wound examined: if every thing now looks well, and there is little or no pain, or inflammation, the *sutures* are to be left alone for six or seven days, or longer, and the wound dressed till there appears a strict union in the lips. If, in any of these examinations, the stitches of the *suture* are seen to be too loose, they must be tightened, if too tight, loosened. When the lips of the wound appear to be inlarged, or bruised, they must be dressed with a digestive ointment, the continuance of which usually soon takes off those symptoms; but if the wound be attended with great inflammation and a fever, the stitches must be loosened, and the patient blooded, and kept on a thin diet: if this method remove the symptoms, the stitches must be tighted again, and the wound dressed and managed as before; but if this method proves fruitless, and the symptoms continue and increase, the stitches must then be cut, and the wound treated as if there were a loss of substance.

If the wound heals by the assistance of the *suture*, the threads of it are to be cut with scissors, near the knots, and the lower lip of the wound to be suspended with one hand, while the threads are gently drawn out with the other. The punctures that are left from them will easily heal, by injecting the arquebusade water, or spirit of wine, or lime-water, and laying on compresses dipt in the same liquors. *Heister*'s Surgery, p. 39.

SUVERNA *guirecom*, in natural history, a name given by the people of the East-Indies to a kind of fossile, which they esteem greatly for certain imaginary virtues. It is a kind of fine and glossy foliaceous talc. Their manner of preparing it is this: they beat it to pieces in a mortar, and then boil, or rather fry it a long time in butter, and afterwards straining off the butter, they eat it to make them fat.

SWALLOW, in ornithology. See HIRUNDO.

SWALLOW-*fish*. See HIRUNDO *piscis*.

SWALLOW-*fly*, in natural history, the name of the chelidonius, a fly very remarkable for its swift and long flight. See CHELIDONIUS and the next article.

SWALLOW-*stone*, *chelidonius lapis*, in natural history, the name of a stone which Pliny, and many other authors affirm to be found in the stomachs of young *swallows*. It is always described to be small, roundish, convex on the outside, and concave on the other, and of a brownish, yellowish, or blackish colour: this, and the figures given of it, plainly shew that it is either a small species of the lycodontes, or bufonitæ, or else a detached piece of one of the compound ichthyperia, or, as they are vulgarly called, *siliquastra*. These are the bony palates of certain species of fish, and are composed of several parts, the middle ones longish, and resembling the pods of a lupine, and those toward the edges roundish and small, convex on the outside, and concave within, but more hollowed, and consequently thinner than the lycodontes, to which otherwise they are very like in shape. The whole palates, or the long parts, when loose, are called *siliquastra* by authors; but the round pieces have been usually confounded with the bufonitæ, and mistaken for them, whenever they have been found loose. These, as they are thinner and hollower than the lycodontes, agree better than any species of those bodies with the figures and descriptions of the *chelidonii* in the more accurate writers, who make them small, thin, and tender; but the generality confound these fragments of palates, as well under the name of *chelidonii*, as of the bufonitæ, never guessing at their true origin. They are rarely larger than the eighth of an inch in diameter. The common report is, that when two of these *stones* are found in the stomach of one *swallow*, the one is more yellow, the other more red; but that when there is only one, it possesses the virtues of both. De Boot tells us, that he cut up several young *swallows*, but never found any such stones in them; and indeed it is no wonder, since they are not to be looked for there, but in the jaws of the wolf-fish, or in the palates of some of the less known kinds.

SWALLOW-*wort*. See the articles ASCLEPIUS and VINCETOXICUM.

Difficulty of SWALLOWING, in infants. See the article INFANT.

SWAN, *cygnus*, in zoology. See the article CYGNUS.

By the law of England, to take *swans* eggs is penal, in the same manner as taking hawk's eggs, that is, by fine and imprisonment. See HAWK.

SWAN-*shell*. See the article CIGNE.

SWARDY, in agriculture, a term used by the farmers for a soil well covered with grass. *Plot*'s Oxfordsh. p. 247.

SWARM. The signal of the going out of a *swarm* from a hive is sometimes only a humming noise made by one single bee, but that a very particularly acute, and clear sound: this seems to be the voice of the new queen, or female bee, calling together the *swarm* that is to follow her out, and animating them with a sort of martial music for the great adventure they are going to engage in.

Some who have pretended to be extremely well versed in the language of bees, as Butler, and others, say, that this is a voice of intreaty, by which the young queen begs permission of the old queen, or parent of the hive, to take out a *swarm* with her to some other place: they say this noise of intreaty usually lasts about two days, and that at the end of that time, if the parent grants the request, she is heard to answer with a louder and clearer voice of the same kind. These noises are not to be heard, unless the ear be applied close to the place; and they say, that when this last found is made, the new *swarm* may be expected certainly to go out the next day, if the weather be proper.

But he seems to have taken great pains to distinguish these sounds; he gives all the modulations of the voice of the young female, and every note that she runs into; and observes, that all these are notes of supplication, and that the sounds issued by the parent, or reigning queen of the hive, have an air of majesty, and are greatly different; and adds, that if the young female attempts to make the sounds of the reigning bee, it is looked upon as a rebellion in the hive: and he pretends to be acquainted with the proceedings against her in these cases; he says she loses her head, and that several of the bees that followed her are treated in the same manner for having been seduced to a rebellion. *Reaumur*'s Hist. Insect. Vol. 10. p. 290.

All these different modulations of sounds, made by the bees, are the effect of the different vibrations of their wings in the air. It has been supposed by Swammerdam, that the air issuing from the stigmata of the body was very instrumental to the making of this sound; but this is proved to be an erroneous conjecture, by the easy experiment of cutting off a bee's wings, which always renders the creature perfectly mute; though this could not be the case, if the voice proceeded from other parts. It is evident, therefore, that all the sounds of the bee are made by the striking of its wings against the air; and it seems very easy to imagine, that when the motion of the wings can make a sound, the more quick or slow motion of them can modulate it in a different manner, and the moving them in several different directions, may also add greatly to the variety.

The hours of going out of *swarms* are always between eleven in the morning, and three in the afternoon: the air is at this time very hot, and the sun often shines brightly on the surface of the hive; the effect of this, in causing them to go out, is easily conceived. The few who are nearest the mouth of the hive, and are ready to follow their queen, soon find that this is a pleasant season for their expedition, and the numbers of others, which remained irresolute in the inner parts of the hive, now find the natural heat of the place increased to so great a degree by the action of the external warmth, that it is very natural for them to resolve at once to depart with those which are going off, in order to find a place where they may be more at ease, or less crowded and heated in their habitation. People, who have the care of bees, should attend to their *swarming*, or going out on these occasions; and if they are not at leisure to watch them in the hours before mentioned, should defend the hives, during that part of the day, from the heat of the sun, that they may not go off and be lost.

Immediately before the going out of a *swarm* there is heard a prodigious humming in the hive, much greater than what is heard at any other hive, and immediately after this, the openings of the hive are crowded with bees, in a violent hurry to get out; those which first come out immediately take flight, and if the female, or queen, be among these, vast numbers immediately follow, and the air is seen as full of them, as it is of flakes of snow in a winter storm; and, in fine, it is not a minute before all the bees, that are to make the new *swarm*, are out of the hive: when the body is thus joined, they rise and fall in the air, and seem very curious in choosing a place where to fix themselves. It does not appear that the female bee chooses the place for them, but they all seem to be assistant in it; and as soon as they have fixed upon a proper branch of a tree, or the like, they all fly towards it, and begin to form a cluster in one part of it. The female does not place herself at the head of this cluster, but sits on the branch near it, to see how she approves the management; as soon as the cluster is of a proper size, she adds herself to it, and from that instant it thickens in a surprising manner, all trying first to fix themselves to the rest, so that in a quarter of an hour they are all collected together into a vast mass, hanging to one another by the legs. In this condition they remain absolutely quiet, though exposed to the open air, and there are no more of them seen flying loose about, than there are about the hives in a summer's day. *Reaumur*'s Hist. Inf. Vol. 10. p. 293.

The hives of bees are commonly placed in gardens, that the bees may have some flowers at least in their own neighbourhood, and not be compelled to go far in search of food; and the *swarms* from these hives always succeed best, when there

there are fome bufhes, as of filberts, barberries, or the like, in the garden, as well as high trees; for when the bees take a high flight, they often take a very long one before they fettle, and fometimes go fo far, that the eye cannot trace them to the place of their fettling; in which cafe, all attempts to fearch for them are ufually vain, and they are loft entirely. The low bufhes in view ufually determine them to low flights, and if they are feen to be afcending too high, the cuftom is to throw handfuls of duft and fand upon them; this ufually brings them down, as they probably miftake the particles for drops of rain.

Another very antient cuftom, and which is continued to this day, is the beating on inftruments of brafs, and the like, to make a great noife, while they are gathered in the air: it is pretended, that this difpofes them to fix themfelves the fooner. The origin of this cuftom has been an obfervation, that thunder always fends thofe bees, which are abroad, from the flowers back to the hive, and it is fuppofed that this artificial noife may have the fame effect; but in all probability, the bees are better acquainted with thunder than to be thus deceived: there is indeed much more probability of their miftaking the particles of duft, falling upon their backs, for drops of rain, than taking fo unlike a found for thunder; for it is found by experience, that the making all the noife that can be conceived, this way, never was able to drive one bee from a flower where it was bufy, or to fend one ftraggler home.

When the time of a *fwarm*'s going out of the hive is expected, the people, who have the care of them, fhould always be prepared with a hive to receive them; and when the *fwarm* fettles upon fome branch of a bufh, or low tree, the hiving of them is an eafier matter than could be imagined. See Hiving.

The nature of the annual new *fwarms* of bees, which we fee depart from old hives, are not to be truly underftood, otherwife than by knowing the hiftory of the propagation of the fpecies among thefe animals, for which fee the articles Bee, and Queen *bee*.

The queen, or mother bee, which is the general parent of the hive of bees, continues laying eggs, in greater or leffer number, during the whole fummer months, but in the winter months fhe defifts; and many bees perifh in the end of the autumn, and during the courfe of the winter, without the hive's having any fupply from the female: by this means there are but a fmall number of bees left, when there is but a fmall provifion in ftore for them, as they are to live on their labours of the former fummer. As foon as the fpring comes on, and there appear flowers, out of which honey may be obtained, the parent bee begins to lay again; and by the vaft number of eggs fhe lays every day, foon provides a fupply to repair the lofs. All thefe eggs are hatched, in two or three days after they are laid, into worms; and, in fine, they appear under the form of bees, and are fit for working, in about three weeks time.

All the eggs that the female lays, during the firft week or two, are for the production of the common, or working bees, as they are the more neceffary at that time: after this fhe begins to lay eggs which are to produce drones, whofe whole period of life is to be only of a few months, and who are never to work, but to feed on the labour of the others; they being the males of the hive, and all their bufinefs being to impregnate the eggs of the females for future fupplies of young; and this office they are to perform, as well to this their parent, as to their fifter female, that is to be hatched from an egg laid afterwards in a peculiar cell. According to this rule we fee, about the month of May, a great number of drones in a hive, where, before that time, there was not one, and foon after the appearance of thefe we find a new female, hatched out of an egg laid on purpofe at a proper time; and fometimes the fame hive affords two or three of thefe females. *Reaumur*, Hift. Infect. Vol. 10. p. 285.

All the time that this female, and thefe males, or drones, are hatching, the number of common, or working bees, is alfo increafing very faft, by a numerous progeny hatching every day from the eggs of the parent; and the confequence of this is, that the number becomes too great to be contained in the hive. It is neceffary then, that a certain number fhould go off in form of a colony, and fettle themfelves in fome other place; this is foon refolved, and the number thus detached from the reft is what we call a *fwarm*. This however they would never do, had they not a chief to lead them, and promife a future progeny for the object of their cares and labours; but as with them, when they become numerous, there is always hatched at leaft one female, fhe places herfelf at their head, and leads them out to feek a new abode. If by any accident fhe is killed, they will never enter a hive at all, but fly feparated during the whole fummer, and take no care but of the feeding themfelves. This alfo is carried fo far among them, that if the hive be never fo full, and there be no young female among them, none of the bees will ftir, but they will hang in clufters out at the mouth of the hive; and, on the contrary, if a hive be but half peopled at the time that a young female is produced, as foon as fhe is able to go away, and to lay her eggs, the half, or at leaft fome confiderable part of thefe few bees, will leave the hive, though they have plentiful room in it, and form a new *fwarm*: fo that though the overfulnefs of the hives be, in general cafes, one great reafon of the departing of a colony, in form of a *fwarm*, yet it is not the only reafon.

The departure of the *fwarm* ufually happens almoft immediately upon the birth of the young female, or queen. This creature feems to be fœcundated, and ready to lay her eggs almoft as foon as fhe is out of the nymph ftate, and very often actually places herfelf at the head of a company, and goes off within four or five days of her birth in the winged ftate. It may happen, however, that the time of the departure of the *fwarm* may be retarded by accidents, fuch as very rainy, or ftormy weather; for as fuch a feafon would render the *fwarming* abroad very uncomfortable, they ufually ftay in the hive till fuch weather is over, though perfectly ready to go. It is very certain, that though the female is ready to go, fo foon after her birth, to form a new *fwarm*, that her eggs are at that time fœcundated, and ready to produce the young ones; for there often go no drones, or male bees, with the new *fwarm*, and it feems accident, rather than the intent of nature, if any go out with them, as the female is plainly already impregnated, and needs no new impregnation, till fome of her own offspring are able to ferve her. The time of the going out of the *fwarm* is different in different countries, and even in the fame country varies very much, on occafion of the feafon of the year, and the ftate of the hive. *Reaumur*'s Hift. Infect. Vol. 10. p. 288.

If a hive has been very well peopled during the winter, the young progeny go out early in the fpring; and if it have been very thinly peopled, it is fometimes as late as the middle of June before they go out, even without any accidental delay from the want of a queen.

The people who manage bees, are informed of the time when they are going to fend out new *fwarms* by feveral figns. One is, when the hive is fo peopled, that many of the bees cannot find room within, but ftand in clufters on the outfide of the hive; another, is the appearance of a large number of drones, or male bees: thefe, however, are not certain figns, nor do they point out the very day of the *fwarming*; but there is one which declares it very punctually, which is the obferving, that though the hive be very full, and the day very fine, yet very few bees go out in fearch of honey; in this cafe it is a certainty that they are affembling themfelves in the hive, and preparing to be gone in a very little time. If a perfon go near the hives, that are ready to fend out *fwarms*, in the evening, or even in the night, he will hear a fort of humming noife in them, which is not to be heard at fuch times on any other occafion: in fhort, the whole is in agitation on the occafion, and the tumult never ceafes till the new colony goes out.

Swarms *of infects*. We have an account [1] of an extraordinary *fwarm of infects* in New-England, that deftroyed all the trees in the country for the fpace of two hundred miles. It is faid there were found a great number of holes in the ground, out of which thefe creatures broke forth in the form of maggots, which became flies with a kind of tail or fting, which they ftuck into the tree, and thereby envenomed and killed it.—[[1] Philof. Tranf. N° 8. p. 137.]

SWEAT (*Cycl.*)—Many diftemperatures of the body have their rife, as well as their cure, by means of the differences of this evacuation.

The faults of our *fweats*, in regard to the general health of the body, are reducible principally to three kinds. 1. They are too exceffive: thefe ufually happen early in the morning, as foon after three o'clock, and are in fome degree periodical; but in others they are rather continual, or have very few intermiffions. 2. The ufual and habitual fecretions by *fweat* are fubject to be impeded, or retarded, and hence many diftempers take their rife. And 3. there is in fome particular people a remarkable difficulty of being brought to *fweat* at all.

The perfons principally fubject to too profufe *fweats*, are men of a plethoric and fanguineo-phlegmatic temperament; thefe, on the flighteft motion of the body, are ufually thrown into profufe *fweats*; and the fame perfons are ufually fubject to violent nocturnal *fweats* in the fpring and autumn feafons. Perfons in hectics alfo, when near the time of their death, ufually fall into profufe nocturnal *fweats*, which are always a fatal prognoftic.

The perfons principally fubject to a natural difficulty of *fweating*, are thofe who have a mucous and thick dyfcrafy of the humors; and fometimes perfons of very tender and delicate conftitutions, who are fubject to emotions of the blood, and are continually thin in flefh.

Prognoftics in fweats. A profufe *fweat*, though it confiderably waftes the flefh and ftrength, yet is lefs dangerous when left to itfelf, than when rafhly fuppreffed. The confequences of habitual *fweats* being fuppreffed, are ufually according to the habit and difpofition of the patient, either cutaneous eruptions, as the itch, and the like; or catarrhs, coryzas, and

and gravedos; and fometimes they bring on congeftions, inflammations, and convulfions.

Method of treatment. So long as *fweats* bring on no bad fymptoms in illneffes, they are to be rather promoted than checked, even though they may feem profufe in quantity; and in this cafe, the proper regimen is a moderate warmth, a quiet ftate of the body, and frequent draughts of warm liquors; but when the ftrength is found to be too much exhaufted by thefe *fweats*, fmall dofes of nitre are found of great fervice.

When different diforders arife from the fuppreffion of *fweats*, nothing is of greater fervice than the compound powder of antimonium diaphoreticum, crabs eyes, and nitre, given in fmall dofes every three hours; and a quiet pofture of the body is to be ordered, which greatly tends to promote *fweating*; and frequent draughts of warm and weak liquors are to be taken, and the bowels are to be relaxed with a clyfter, or a gentle purge, if there be no fymptom neceffarily forbidding it. In regard to thofe perfons, who are naturally very difficult to be *fweated*, a draught made of frefh arum-root and wine, or vinegar, ufually brings on profufe *fweating*, if they are put to bed, and warm liquors drank afterwards. It is a very good general caution, that profufe *fweats*, if they have continued ever fo many months, are never to be repreffed by aftringents; for in that cafe they are ufually attended with fymptoms much worfe than the original complaint. The common method of forcing out fuppreffed *fweats* by the hot alexipharmics, and volatile falts, is by no means advifeable in any cafe. Bleeding, judicioufly timed, is often of very great fervice in promoting *fweats*. When the natural *fweats* of children are repelled, they become fuddenly feverifh and ill, and nothing relieves them till the *fweats* are recalled. This may be done fimply, by keeping them warmer than before, in moft cafes; but when that fails, the gentle abforbents are to be prefcribed, and if they fuck, the nurfe may take the common alexipharmic medicines: crabs eyes are as proper as any thing for the child in this cafe, and for the nurfe the lapis contrayerva. The convulfions of children very often arife from the fuppreffion of their *fweats*, and are always then taken off by making them *fweat* again. *Junker's* Confp. Med. p. 530.

SWEATING-*houfe*. The natives of North-America, when we firft fettled among them, had a great many houfes to *fweat* in, it being their general remedy for difeafes of whatever kind; but at prefent they are lefs ufed among them.

The cave, or *fweating-houfe*, was ufually eight feet in diameter, and four feet high, the roof being fupported by fticks, or boards. They ufually dug thefe caves in the fide of a hill, and as near as could be to fome river, or pond. The entrance into the cave was fmall, and when any perfon was *fweating* in it, the door was covered with a blanket, or fkin. Near the cave they ufed to make a large fire, and heat in this a quantity of ftones, perhaps five hundred weight; thefe they rolled into the cave, and piled up in a heap in the middle. When this is done the Indians go in naked, as many as pleafe, and fit around the heap of ftones; and as foon as they begin to grow faint, which is ufually in a quarter of an hour, they come out, and plunge themfelves all over in the water, remaining in it a minute or two; and repeating this a fecond time, they drefs themfelves, and go about their bufinefs.

This has been for many ages ufed among them with fuccefs, in cafes of colds, furfeits, fciaticas, and pains fixed in their limbs, and the Englifh have often ufed the fame means, and found relief by it. It is practifed equally at all times of the year, and the Indians do it not only in fickneffes, but by way of refrefhment after long journies, and other fatigues, and to ftrengthen themfelves for any expeditions. Philof. Tranf. N° 384. p. 131.

Turf SWEATING. See TURF-*fweating*.

SWEATING-*iron*, in the manege, is a piece of a fcythe about a foot long, and of the breadth of about three or four fingers, very thin, and fuch as cuts only with one fide. When a horfe is very hot, and the grooms have a mind to leffen the *fweat*, or make it glide off, they take this knife or iron in their two hands, and gently run the cutting edge along the horfe's fkin, commonly with the grain, or as the hair lies, and but feldom againft it; with intent to fcrape off the *fweat*, and dry the horfe.

SWEATING-*room*. See an account of the remains of a Roman *fweating-room* in the Philofophical Tranfactions, N° 461. fect. 29.

SWEATING-*ficknefs*. See SUDOR *Anglicanus*, *Cycl.* and *Suppl.*

SWEET (*Cycl.*)—By a *fweet* is underftood any vegetable juice, whether obtained by means of fugar, raifins, or other foreign or domeftic fruit, which is added to wines, with a defign to improve them. It is plain, from the making of artificial muft, or ftum, by means of fine fugar, with a fmall addition of tartar, that the art of *fweet*-making might receive a high degree of improvement, by the ufing pure fugar, as one general wholefome *fweet*, inftead of thofe infinite mixtures of honey, raifins, fyrups, treacle, ftum, cyder, &c. wherewith the *fweet*-makers fupply the wine-coopers to lengthen out, or amend their wines: for pure fugar being added to any poor wine, will ferment therewith, and improve it, and bring it to a proper degree of ftrength and vinofity. If the wine that is to be amended is tart of itfelf, no tartar fhould be added to the fugar, but if it be too *fweet* or lufcious, then the addition of tartar is neceffary. *Shaw's* Lectures, p. 203. See the article *Artificial* STUM.

SWEET *fublimate of mercury*. See MERCURIUS *dulcis*.

SWEET *corn*, a term ufed by the Indians to exprefs a fort of corn they are very fond of, and generally keep in their houfes.

While the ear of the maiz, or Indian corn, is yet green, but full, they gather it, and firft boil, and afterwards dry it, and lay it up for ufe in bags, or bafkets. When they eat it, they boil it again, either whole, or grofsly beaten in a mortar; they then mix it with fifh, or with venifon, or beaver flefh, and account it a very fine difh. The green ears, or frefh *fweet corn*, they alfo fometimes eat, as foon as it is gathered, roafting it before the fire, and then picking out the grains. This is a new fupply of food for them many times, when their winter, or laft harveft-ftore is exhaufted. Their foldiers alfo commonly go out to war againft their enemies about this time of the year, and find this fupply in their enemies fields. See GUINEA *corn*.

SWEET-*Williams*, the Englifh name of feveral fpecies of *cariophyllus*, or pink. See the article PINK.

There is a great variety of fpecies, and very elegant diverfities of colouring in thefe flowers; the principal difference, however, is between the fingle and double kinds.

The fingle kinds are to be propagated by fowing their feeds in March on a bed of light earth; in May they will be ready to plant out, and muft then be fet at fix inches diftance in beds of the fame kind of earth. In thefe beds they fhould remain till Michaelmas, and then be tranfplanted to the places where they are to remain. They will flower the next year in May, and ripen their feeds in Auguft, when that of the beft flowers fhould be faved.

The double kinds are propagated by layers in the fame manner with the carnations, they love a middling foil, neither too light, nor too ftiff; they continue flowering a long time, and are very beautiful, efpecially the mule-kind, which produces yearly two full blooms of flowers, the one in May, the other in July. *Miller's* Gardner's Dictionary.

SWELLING (*Cycl.*)—*Swellings* in the face and falivary glands, without any fever, or rednefs of the fkin, fometimes happen in fummer months, and often give way to a gentle purge or two. See Medic. Eff. Edinb. Abridg. Vol. 1. p. 65.

Thefe *fwellings* are fometimes erifipelatous, and fall chiefly on the forehead and eyelids, and yield to purges and blifters. Ibid.

SWIFT, in zoology, a name given by many to the common newt, or eft. See the article EFT.

SWIFTERS, in a fhip, ropes belonging to the main-mafts and fore-mafts, which help to fuccour or ftrengthen the fhrowds, and to keep the mafts ftiff: they have pendants faftened under the fhrowds, at the head of the mafts, with a double block, through which the *fwifter* is reeved; which at the ftanding part has a fingle block with a hook, hitched into a ring at the chain-wale, and fo the fall being haled up, helps to ftrengthen the maft; yet it is belayed about the timber heads of the lower rails aloft.

SWIFTING *of a boat*, is compaffing her gun-wale round with a good rope, to ftrengthen her in ftrefs of weather, that fhe be not fhattered by the violence of the fea.

SWIFTING *the capftan-bars*, aboard a fhip, is ftraining a rope all round the outer ends of the capftan-bars, in order to ftrengthen them, and make them bear all alike, and together, when the men heave or work there.

SWIFTING *of a fhip*, is either bringing her aground, or upon a careen; for then they ufe to *fwift* the mafts, to eafe and ftrengthen them, that all the weight may not hang by the head; which is done by laying faft all the pendants of the *fwifters* and tackles with a rope clofe to the maft, and as near to the blocks as can be; and then to carry forward the tackles, and there to bowfe, or hale them down as hard and taught as poffible. The word of command here, is, *Ho! bowfe men!* All this is done alfo to keep the maft from rifing out of the ftep.

SWIGGING, a particular way of caftrating rams.

The operation is performed by throwing the creature on his back, in which pofture he is held; then a ftring is drawn about his tefticles as tight as poffible, and fixing it there, the part is anointed with frefh butter. The beaft is then left to feed, and in two or three days the tefticles grow fo rotten, as to fall off with the ftring, or may be plucked away with a fmall force. *Boyle's* Works Abr. Vol. 1. p. 87.

SWIMMING *of fifhes*. See NATATIO, and AIR-*bladder*.

SWINE, *fus*. See the article SUS.

Swine are very profitable creatures to the owner, being kept at fmall expence, feeding on things that would be otherwife thrown away, and producing a very large increafe. They are apt to dig up the ground, and to break fences; but this may be prevented, by putting rings in their nofes, and yoaks about their necks. Leicefterfhire, Northamptonfhire,

ſhire, and Hampſhire, are famous for theſe animals, which ſeems owing to their being clayey countries, and that more beans and peaſe are ſown there, than in other places. The wild kind never grow ſo large as the tame, but they are much better taſted. The keepers of hogs ſhould always chooſe ſuch boars to breed out of as are long bodied, and have deep bellies and ſides, ſhort noſes, thick thighs, ſhort legs, high claws, a thick neck, and a thick chine, well ſet with large briſtles.

It is not proper to keep too many breeding *ſows*; for they will produce ſo many young at a time, and this three times a year, that they will not find food enough. They uſually bring thirteen or fourteen young ones in a litter, ſometimes more, but they can bring up no more than they have teats to ſuckle; and they bring forth three times in a year. Young ſhoots, as they are called, that is, *ſwine* of three quarters of a year old, are beſt for pork, and thoſe of a year and half, for bacon. Moiſt and ſedgy grounds are good for *ſwine*, for they eat the roots of many of the plants that grow there; and the fruit of the beech, cheſnut, and hedge buſhes, fatten them well, and make their fleſh much better taſted, than when bred intirely in the ſtye. *Mortimer's* Huſbandry, p. 253.

SWINE-*pipe*, in ornithology, a name uſed in many parts of England for the red-wing.

SWING-*wheel*, in a royal pendulum, that wheel which drives the pendulum. In a watch, or balance clock, it is called the *crown-wheel*.

SWINGING was preſcribed by antient phyſicians, as a good exerciſe in ſome caſes. See AGITATION.

SWINGLE, in the wire works in England, the wooden ſpoke which is fixed to the barrel that draws the wire, and which, by its being forced back by the cogs of the wheel, is the occaſion of the force with which the barrel is pulled. *Ray's* Engliſh Words, p. 133.

SWINGLING. See the article BRAKE.

SWIT, in natural hiſtory, a name given by the people of the Philippine iſlands to a very ſmall bird of the humming bird kind, frequent in that part of the world. It is beautifully coloured, and lives on the honey of flowers.

SWORD (*Cycl.*)—SWORD-*hand*, in the manege, is the horſeman's right hand, as *bridle-hand* is uſed to denote his left hand.

Pleas of the SWORD. See PLEA, *Cycl.* and JUS *gladii*, *Suppl.*

SYCABIS, in zoology, a name by which ſome authors have called the *atricapilla*, or black-cap, a ſmall bird well known in England. See ATRICAPILLA.

SYCAMINOS, a word uſed by ſome for the mulberry fruit, and by ſome for the tree.

SYCAMORE-*tree*, a name improperly given by us to the *acer majus*. See the article MAPLE.

SYCAMORE-*moth*, in natural hiſtory, the name of a peculiarly large and beautiful moth, or night butterfly, ſo called, from its caterpillar feeding on the leaves of the *ſycamore*.

This caterpillar is remarkably large, very often growing to three inches and an half long, and three quarters of an inch in diameter. The head is ſmall, and the body conſiſts of twelve rings, each of which has five or ſix large and ſtiff hairs on it, each having at its extremity a ſmall, but hard globule of a blue colour, from which there often ariſe alſo ſeveral other hairs, ſmaller and ſhorter than the others, and having one in the middle a little longer than the reſt; on nine of the rings alſo there is above each foot a white oval mark, ſurrounded by a black line; theſe Malpighi diſcovered in the ſilkworm to be the organs of reſpiration.

This caterpillar has ſixteen feet, diſpoſed in three ſeries, or ranges; ſix are placed near the head, theſe ſtanding very cloſe together, eight more ſtand in the middle of the body, and the other two near the tail: the ſix that are placed near the head, are the only true feet, for the reſt ſerve as well to fix the creatures to any particular place, as to aſſiſt them in their motions. The ſkin is yellow and ſmooth, without a ſingle hair, except thoſe particularly before mentioned. Theſe caterpillars being put into a box, each ſpun itſelf a ſtrong and firm caſe, which it faſtened to the ſide of the box, and in it waited the time of its laſt transformation: in each of theſe ſhells there was left a ſmall aperture, by means of which the creature was to get out when in its butterfly ſtate, and the head of this animal was placed exactly againſt this aperture. In this ſtate they lie all the autumn, winter, and ſpring, and in the beginning of ſummer come out in the ſhape of a very elegant moth. The wings, when expanded, meaſure more than five inches, and each has an eye, like that on the peacock's tail, near the extremity. The horns are of the feathered kind, and are very large and elegant; and the body and origins of the wings are covered with very long hairs. Mem. Acad. Par. 1692.

SYCION, a word uſed by ſome authors to expreſs a decoction of dried figs.

SYCITES, the *fig-ſtone*, an idle name given by ſome authors to ſuch natural nodules of flint or pebbles, as happen to approach to a fig in ſhape.

SYCITES *vinum*, a term uſed by the antients to expreſs a wine impregnated with figs.

SYCOMANTIA, Συκομαντεια, in antiquity, a ſpecies of divination performed with fig-leaves; for which ſee *Potter*, Archæol. Græc. lib. 2. cap. 18. Tom. I. p. 353.

SYCOSIS, a term uſed by ſome authors to expreſs a tumor of the anus, differing only in bigneſs from the thymus. It had this name from the reſemblance of the fleſh about its edges to a ripe fig. The antients underſtood two ſorts of ulcerated tumors by this name, tho' both attending the ſame part; the one was hard and round, the other ſofter, and of an irregular figure: from the firſt there was diſcharged only a ſmall quantity of matter, from the latter a very large quantity, and that of a very ill ſmell. Some other of the antient phyſicians make the ſame word alſo expreſs two ſorts of ulcerated tumors of the head, or beard, which they diſtinguiſh by the ſame characters into a hard and a ſoft one.

SYCOTA, a word uſed by ſome of the antients to expreſs a ſort of food prepared of figs.

SYCOTON, a name given by the antients to the liver of a pig fed with figs. This was eſteemed a very elegant diſh among the old Greeks.

SYDEROPŒCILUS, in natural hiſtory, the name of a ſtone mentioned by the antients. It was found in Arabia, and ſeems to have obtained this name from its being ſpotted with a ferrugineous colour. The deſcriptions of the antients are, however, in this, as in many other inſtances, too ſhort to ſuffer us to gueſs what ſtone they meant. This might poſſibly be a granite with ſpots of this peculiar colour.

SYENITES, in the natural hiſtory of the antients, a name given by many to the granite, the ſame with the oriental granite of the moderns. It had this name from its country; but our artificers have of late learned to call a very different ſubſtance by a name that ſounds very like this, the beautiful purple and yellow marble, ſo frequent with us now in tables, *&c.* being called among them *Sienna marble*. *Hill's* Hiſt. of Foſſ. p. 500.

SYLVA (*Cycl.*)—SYLVA, among the Romans, a ludicrous kind of hunting exhibited in the circus; ſo called, becauſe the circus was really planted with trees, which had been dug up with the roots by the ſoldiers and brought thither, and fixed to large beams, after which earth being thrown upon their roots, the circus actually reſembled a wood; then being filled with all ſorts of herbivorous animals, the people were let looſe upon them, and carried all clear off. *Pitiſc.* Lex. Ant. in voc.

SYLURUS, in ichthyology, a name given by Geſner to the *ſilurus* of Willughby, and others, which we call in Engliſh the *ſheat-fiſh*.

The names of fiſh are in general ſo arbitrary, that it is not eaſy to determine what is meant by them in the different authors who uſe them: but Artedi has very well diſtinguiſhed this by the name of the *ſilurus* with four cirri, or beards, at the mouth; by which it evidently is diſtinguiſhed from the fiſh called the *lake*, which, though a true *ſilurus*, has only one beard.

SYMBACCHI, Συμβακχοι, in antiquity, a deſignation given to the two men, who purified the city of Athens at the feſtival *Thargelia*. See THARGELIA.

SYMBOLISM, a word uſed by ſome of the chemical writers to expreſs a conſent of parts.

SYMBOLOGICE is uſed by ſome for that part of the ſcience of medicine, which treats of the ſymptoms of diſeaſes.

SYMPARATAXIS, a word uſed by Hippocrates to expreſs the conflict between nature and a diſeaſe, and the aliments or medicines given in it.

SYMPASMA, a word uſed by many authors to ſignify a cataplaſm.

SYMPATHETIC *inks*. See *Sympathetic* INKS.

SYMPATHETIC *powder*. The compoſition of the *famous ſympathetic powder*, uſed at Goſſelaer by the miners in all their wounds, is this. Take of green vitriol eight ounces, of gum tragacanth, reduced to an impalpable powder, one ounce; mix theſe together, and let a ſmall quantity of the powder be ſprinkled on the wound, and it immediately ſtops the bleeding. The vitriol is to be calcined to whiteneſs in the ſun, before it is mixed with the gum.

SYMPATHY, (*Cycl.*) in medicine. A part is ſaid to ſuffer by *ſympathy*, or conſent, when it is yet whole and ſound, and is only affected by the fault of ſome other part. Medic. Eſſ. Edinb. Abridg. Vol. 1. p. 449.

We have ſome practical remarks on the *ſympathy* of the parts of the body, in the Medical Eſſays of Edinburgh, Vol. 5. Art. 45.

SYMPESIS, a word uſed by the old Greek writers to ſignify concoction, or digeſtion.

SYMPHONIACA, in botany, a name given by ſome authors to the common *hyoſciamus*, or henbane. *Ger.* Emac. Ind. 2.

SYMPHONIALE, in the Italian muſic, is ſometimes prefixed to a canon, or fugue, to ſhew that it is at uniſon, *i. e.* that the ſecond part is to follow, or imitate the firſt in the ſame intervals, ſounds, notes, *&c.* the third to obſerve the ſame with regard to the ſecond, and ſo on.

SYMPHYTUM, *comfrey*, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe. The cup is an erect, acute, pentagonal perianthium, divided

divided into five segments at the rim, and remaining when the flower is fallen. The flower consists of one petal, formed into a very short tube, with a bellied tubular end, somewhat thicker than the tube, the extremity of which is divided into five segments. The opening of the flower has five tapering rays, shorter than the rim of the flower, and converging, so as to form a sort of cone. The stamina are five tapering filaments, placed alternately with the rays of the mouth of the flower; the antheræ are acute, upright, and covered. The pistillum has four germina. The style is slender, and of the same length with the flower. The stigma is simple. The cup becomes inlarged, and supplies the place of a fruit, containing four pointed gibbous seeds, with their tops converging one towards another. *Linnæi* Gen. Plant. p. 38.

The characters of *symphytum*, according to Tournefort, are these. The flower consists of one leaf, and is funnel-fashioned, but somewhat resembling the bell-shaped ones. The cup is divided into segments, even to the base, and from this there arises a pistil, which is fixed in the manner of a nail to the hinder part of the flower, and is surrounded with four embryos, which afterwards ripen into so many seeds: these are of the shape of a viper's head, and are contained in the cup, which becomes inlarged for their reception.

The species of *comfrey*, enumerated by Mr. Tournefort, are these. 1. The great purple-flowered *comfrey*. 2. The great bluish purple-flowered *comfrey*. 3. The white or yellowish-flowered great *comfrey*. 4. The deep yellow-flowered great *comfrey*. 5. The great *comfrey*, with variegated flowers. 6. The tuberose-rooted larger *comfrey*. 7. The smaller tuberose-rooted *comfrey*. 8. The large echium-leaved *comfrey*, with red roots, and yellow flowers. 9. The large echium-leaved *comfrey*, with red roots, and white flowers. 10. The narrow-leaved *comfrey*, with red roots, and yellow flowers.

Authors have been used to reckon another species of this plant, the little borage-like *comfrey*; but this is properly a species of omphaloides. *Tourn.* Inst. p. 138.

The roots of the common *comfrey* are very powerful agglutinants. The common people use them with success in fresh wounds, and a conserve of them is found of excellent use in hæmorrhages of all kinds. They have been also recommended in the gout and sciatica, as of great virtues in mitigating the pain, and shortening the paroxysms.

Symphytum was a name given among the antients to several different plants, which had the common virtues of agglutinators. We have appropriated the word to *comfrey*; but Dioscorides plainly uses it sometimes as the name of elecampane, and sometimes as that of the common horse-tail. He even seems to have led himself into an error in the use of these synonyms, in this very article, having prescribed the horse-tail, under the name of *symphytum*, for a shortness of breath. It is very evident, from the tenor of his other works, that he meant to prescribe the helenium, or elecampane, that having the qualities necessary in such a case; and neither this author, nor any other, ever having recommended the horse-tail on any occasion of this kind. Pliny has collected the virtues and characters of the *symphytum* from all the authors he had, in whom the word occurred, and therefore he has given a list of virtues that belong to no one plant.

SYMPLEXIUM, in natural history, the name of a genus of fossils, of the class of the selenitæ, but not of the determinate and regular figure of most of the genera of those bodies, but composed of various irregular connections of differently shaped, and usually imperfect bodies.

The word is derived from the Greek, συμπλεκω, to connect, or compound a mixt mass of different things.

The bodies of this genus are of an irregular figure, and are variously notched, divided, and indented at their edges: they are composed of a number of other imperfect selenitæ, principally of the rhomboidal kind, though not unfrequently with the columnar, and usually with parts of tabular masses among them. The different bodies that form this kind are seldom quite perfect, having usually fallen together before they were wholly hardened; but generally, whether they form a larger or a smaller mass, they together affect the external figure of a flat hexaedral column, though variously notched at the sides, and truncated at the ends. *Hill's* Hist. of Foss. p. 124.

SYMPLOCE, Συμπλοκη, in rhetoric, a figure, where the same word is repeated several times in the beginning or end of a sentence: thus, *Quis legem tulit? Rullus. Quis majorem populi partem suffragiis privavit? Rullus. Quis comitiis præfuit? Idem Rullus. Voss.* Rhet. lib. 5. p. 289.

SYMPOSIARCH, Συμποσιαρχος, in antiquity, the director, or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided; sometimes by another named by him; and at other times, especially in entertainments provided at the common expence, he was elected by lot, or by the suffrages of the guests. He was otherwise called *basileus*, *rex*, and *modimperator*, &c. and determined the laws of good fellowship, observed whether every man drank his proportion, whence he was called *ophthalmus*, *oculus*, the *eye*. The guests were in all things obliged to obey his commands; on which account Cicero upbraids a certain person, that *qui nunquam populi Romani legibus paruisset, iis legibus, quæ in poculis ponebantur, obtemperabat*: he, who had never submitted to the laws of the Roman people, yielded obedience to those of drinking.

Arian reports, that the king being elected by lots commanded in this manner, *do you drink*, *do you fill the glass*, *do you go*, *do you come*, &c. The chief magistrates were not exempted from yielding obedience, if the lots gave another the preeminence. Plutarch relates, that Agesilaus, king of Lacedæmon, being chosen *symposiarch*, gave the following command to the cup-bearer, who asked him how much wine every guest should drink, *viz. If there is plenty of wine, let every man have what he calls for*; *if not, let every man have an equal share.*

SYMPTOSIS, a word used by the antients to express a contraction, or subsidence of the vessels, such as happens under evacuations. It also is sometimes used to express a remission in a disease, and the falling away in flesh of people in sickness.

SYNAGELASTIC, an epithet used to express the fishes of the gregarious kind, or which swim together in large shoals, in opposition to the solitary kinds.

SYNAGRIS, in zoology, a fish caught in the Archipelago, and some other seas, and much resembling the *dentex*. Some have used it as a synonym for that fish, and others accounted it only a name applied to the *dentex* while young, but it is properly a distinct species. It is considerably shorter and thicker than the *dentex*, and much resembles the carp in figure. Its head is yellow, and its sides are variegated with bluish, and other coloured lines, laid in an oblique direction; but the longitudinal side lines are black. Its scales are remarkably round in figure, and its tail very forked. *Bellonius* de Pisc.

Aristotle, Athenæus, and others, apply the name *synagris* to the fish generally called the *dentex*, or *synodon*, the *dentale* of the Italians.

According to Artedi, it is a species of the sparus, and is distinguished by him by the name of the variegated *sparus* with a sharp back, and with four large teeth.

SYNARTHROSIS (*Cycl.*)—The articulation of bones, so joined together as to remain fixed in their situation, is of two kinds; one is made by ingrailing, and the other in the same manner, in which a nail, or pin, is fixed in wood. The first of these may be again subdivided into the deeper, and the more superficial kind.

The deep kind is observable in the articulation of the broad bones; the antients term this a suture, from the resemblance it bears to a coarse seam, as is seen in the upper bones of the skull. It is made by jags, notches, and holes, in each of the articulated bones, by which they are mutually indented, much after the same manner as what is called *dove-tailing* among the joiners. By the antients this was called also *unguis*, probably because the indented pieces are rounded like nails. Sutures have been divided also into the true and the false. See SKULL.

The other kind is that which is observed in bones joined together by more extended surfaces, in which no indentation appears outwardly. This kind of articulation the antients termed *harmony*; and the articulation of some of the bones of the upper jaw were given as examples of it. But though they describe this as running in a single line, they did not mean this in a strict sense, but only that the joint was like that of two rough boards without grooves; for they have expresly told us, that some small inequalities might be observed in these joints, and some of them have used the terms *suture* and *harmony* indifferently. The other kind of *synarthrosis*, an example of which we have in the teeth, is called *gomphosis*, a Greek term, still retained. *Winslow's* Anatomy, p. 15.

SYNATHROISMUS, Συναθροισμος, in rhetoric, a figure which, in order to magnify a thing, whether good or bad, enumerates a great many different persons, actions, *&c.* to which it relates: thus Cicero, *qui mihi fratrem optatissimum, me fratri amantissimo, liberis nostris parentes, nobis liberos; qui dignitatem, qui ordinem, qui fortunas, qui amplissimam rempublicam, qui patriam, quâ nihil potest esse jucundius; qui denique nosmet ipsos nobis reddidistis.* See *Voss.* Rhet. lib. 5. p. 372.

SYNCAMPE, a word used by the old writers to express the joint, or flexure, where the upper part of the arm is joined to the lower.

SYNCAUSIS, a word used by some medical writers to express the drying, and, as it were, burning up of the excrements within the body, by a febrile heat.

SYNCHISIS, a word used by the old medical writers to express a confusion and perturbation of all the humors in concoction, from the imbecillity of the stomach. It is also used to express a disease of the eye, which consists in a confusion of the humors: this generally proceeds from a violent blow; sometimes from an inflammation of the uvea, occasioning a rupture of the vessels, and an effusion of the humors.

SYNCHORESIS, Συγχωρησις, in rhethoric, the same with *permission*. See PERMISSION.

SYNCHYSIS, Συγχυσις, in rhetoric, a confused manner of expression, where the natural order of the words is perverted. Horace affects it much: thus lib. 1. sat. 5.

Pæne macros arsit dum turdos versat in igne.

SYNCOMISTERIA, Συγκομιστηρια, in antiquity, the same with *thalysia*. See THALYSIA.

SYNCOMISTON, a name given by Athenæus, and some other authors, to the coarser sort of bread eaten by the poor in many countries, and made of unsifted meal, the bran being mixed up among the rest. This is a very nourishing food, and for laborious people, or those who use much exercise, is highly preferable to all other sorts of bread.

SYNCRISIS, a word used by the chemical writers to express a concretion, or coagulation of any thing, effected by a spontaneous, or violent reduction of a liquid substance to a solid one, by a privation of the humid.

SYNCRISMATA, a sort of ointment, of the nature of the acopa, in use among the antients.

SYNCRITICA, a name given by some writers to such medicines as are of a coercive and astringent quality, whether used externally, or given internally.

SYNDESIS, a word used by the antient physicians to express a binding, or straitening.

SYNDESMOSIS, in anatomy, a connection of the bones, called also *synneurosis*.

SYNDESMUS, in anatomy, a word used by some for a ligament. See LIGAMENT.

SYNECHES, in medicine, is the name of a fever of the next degree to the intermittent: it also seems to be something of kin to those, and is called the *continent*, or *remitting fever*. It is a continual fever in regard to duration, though not in degree, continuing many days together without intermission: but then it has its diminutions and augmentations; sometimes regular, sometimes irregular, though no true intermissions. *Allen's* Synopsis, p. 3.

SYNECTICON, a word used by the old writers to express the proximate cause of a disease; called also the *causa continens*, and always remaining closely united with the disease.

SYNERGASMA, a word used by Libavius, and some other authors, to express any operation in chemistry. The operations are by this author divided into two classes, the energetic, and preparatory: the first producing such bodies as are of power to act on others as menstruums, to cure diseases, and the like; and the others producing no such things, but being necessary preparatives to them.

SYNESTIC is sometimes applied by physicians to express the stools when firm, and of a consistence; such as to make them remain in their shape, in opposition to liquid ones.

SYNGENESIA, in botany, a class of plants with hermaphrodite flowers, whose stamina are naturally formed into a single regular congeries.

The word is formed of the Greek συν, together, and γένεσις, formation. The plants comprehended under it are those whose stamina, by the junction of their apices, are formed into a single regular cylindric body; and among these are the lettuce, succory, hawkweed, &c.

The *syngenesia* expresses the same class of plants with the compound flowered plants of Ray, and others. The general characters of the class are these.

The cup is the crown of the seed, and stands on the summit of the germen. The flower consists of one petal, and has a very narrow and long tube placed upon the germen: this is either tubular, ligulated, or naked.

The tubular flower of the *syngenesia* has, at the summit of the tube, a wide campanulated mouth, divided into five segments, which are expanded, and somewhat bent backward. The ligulated flower is that which has a plain and strait edge turning outwards, with a truncated apex undivided, but furnished with three or four teeth. The naked flowers are those which have no mouth at all; and often in these, even the tube is also wanting. The stamina are five very short and slender filaments, inserted into the tube of the flower. The antheræ are of the same number with the stamina: they are slender, erect, and grow together at their sides, so as to form a tubular cylindric body of the length of the mouth of the flower, and divided into five segments at the edge. The germen of the pistil is oblong, and placed under the receptacle of the flower. The style is capillary, erect, and of the length of the stamina, and goes through the cylinder formed by the antheræ. The stigma is divided into two parts, which stand open, and bend backwards. These plants have properly no pericarpium, though in some few species there is a coriaceous crust placed about the seed. The seed is single and oblong, often of a quadrangular figure, and sometimes narrower at the base than in any other part. *Linnæi* Gen. Plant. p. 370.

The seeds are, in the different genera of this class, of a very different appearance at the ends. Some are crowned with a downy matter, composed of a great number of single short filaments, placed circularly, or otherwise, on the head of the seed. In some the downy matter is radiated; in others it is ramose, or branched; and in some it is supported on a pedicle, while in others it stands immediately on the seed. In some genera the seeds have no down at all, but have a small corona, formed of what was originally the cup of the flower: this is permanent, and divided usually into five segments. In some genera the seed is wholly naked, having neither any down, nor this crown of a cup.

The sexes of the plants of this class are very variously disposed, and it is owing to this that there are among them several different kinds of flowers. The tubulated flower is called an hermaphrodite flower, when it contains both the stamina and pistil. It is called a male flower, when it contains only stamina without any stigmata. It is called a female flower, when it contains a stigma and no stamina. And there is still another sort of flower, called neutral, among this class of plants; these have neither stamina, pistil, nor stigma, nor indeed any other part of fructification. These several kinds of flowers are, in the descriptions of the genera, called ligulated, campanulated, &c. from their shape.

A flower composed of a great number of these small flowers is called floscular, or flosculose flower; each of these, from their being small, and only making up a part of a general flower, being called a floscule. The common receptacle of the fructification in the flosculous flowers contains always several floscules; and in the various genera the disk, on which these are received, is either concave, convex, plain, globose, or, finally, pyramidal. This receptacle is called by some *thalamus*.

The superficies of this receptacle is called by authors, in some genera, naked, in others paleaceous. In the naked kinds, it is either absolutely bare, or else covered with a number of small tubercles, or with short and erect hairs. The paleaceous receptacles are covered on the surface with narrow, subulated, and painted paleæ, or chaffy substances. These stand erect, and are placed between the floscules.

The common cup, or perianthium, in these plants, contains, or incloses both this receptacle, and all the floscules: this is contracted together at the top when the plant is in flower, but it expands itself when the floscules are fallen, and the seeds are to ripen. This general cup is, in its different appearances in the several genera, distinguished by authors by the epithet *simplex*, *imbricatus*, and *auctus*. The perianthium simplex, or simple cup, is that which consists of only one simple series of leaves, which surround the flower. The imbricated cup is that which is composed of a vast number of short squammæ, or scales, the exterior ones being gradually shorter than the inner ones, which they lie upon. The calyx auctus is that, in which while one series of long and equal segments surrounds the floscules, another small series surrounds only the base of the inner, simple, and larger cup. The compound flowers are very variously composed, in regard to the nature of the floscules. *Linnæi* Gen. Plant. p. 371.

1. Some are composed of tubulose hermaphrodite flowers in the disk, and of the same sort of tubulous hermaphrodite flowers in the radius. 2. Others are composed of tubulose hermaphrodite flowers in the disk, and of tubulous female flowers in the radius. 3. Some are composed of tubulous hermaphrodite flowers in the disk, and of tubulose neutral flowers in the radius. 4. Some have tubulose hermaphrodite flowers in the disk, and ligulated hermaphrodite flowers in the radius. 5. Some are composed of tubulous hermaphrodite flowers in the disk, and of ligulated female flowers in the radius. 6. Some are composed of tubulous hermaphrodite flowers in the disk, and ligulated neutral flowers in the radius. 7. Some are composed of tubulous hermaphrodite flowers in the disk, and of naked and neutral flowers in the radius. 8. Some are composed of tubulose male flowers in the disk, and of naked female flowers in the radius. And 9. some are composed of ligulated female flowers in the disk, and ligulated hermaphrodite flowers in the radius.

The essential character of a flosculous flower consists in its antheræ growing together into a cylindric body, and producing a single seed, which stands under the receptacle of the separate floscule. Id. p. 372.

The common cup is usual in most genera of this plant, but it is no universal character, for it is wanting in the echinopus. Nor is this the only variation they are subject to, for the common receptacle, which might seem a very essential part of the plant, is wanting in the milleria. It is evident from this, how very uncertain characters the common cup, and common receptacle of the seeds, are in this class of plants; for though they have been judged essential, and unerring marks, yet we find the two plants above named want them severally; and we also find that some plants are possessed of them, which have not the other characters of the class. Thus scabious has a common cup, and dipsacus a common receptacle, yet neither scabious, nor dipsacus, are flosculous, or, as they may much more properly be called, *syngenesious* plants.

It is very remarkable that Plumier has no genus of compound flowers. Tournefort, though he had not the assistances of the later observations on the stamina and antheræ to guide him, yet has fixed very natural genera in the class of the *syngenesious*, or compound flowered plants.

Vaillant made more observations on the nature of the flowers of these plants, than any one who went before him, and the only

only error he run into, was the making too many genera. Pontedera has rendered the method of this clafs very eafy and clear, though he found it very confufed. *Linnæi* Gen. Plant. p. 373.

SYNGNATHUS, in ichthyology, the name of a genus of fifhes, the characters of which are thefe. The coverings of the gills are on each fide compofed of a thin and fingle bony lamella; the head is oblong and compreffed; the jaws are clofed up at the fides; and the mouth is only capable of opening at the extremity of the fnout. The body is long and very flender; the fhape is fometimes roundifh, but more ufually angular. The fins are in moft fpecies four in number, but in fome only one.

The fpecies of this genus, enumerated by Artedi, are four. 1. The fquare-bodied *fyngnathus*, having no fin at the tail. This is the creature called the *hippocampus* by authors. 2. The cylindric *fyngnathus* without any breaft, or tail fins. This is the *acus lumbriciformis* of Mr. Ray. 3. The *fyngnathus* with the middle of the body heptagonal, and with a pinnated tail. This is the *acus Ariftotelis fpecies altera major* of Willughby. 4. The *fyngnathus* with the middle of the body hexangular, and a pinnated tail. This is the common *acus Ariftotelis*. In the diftinguifhing this genus, the number of the incifures, in the body of the feveral fpecies, is to be carefully attended to. *Artedi*, Gen. Pifc.

The name *fyngnathus* is of Grecian origin, and is formed of the word *συν*, which in compofition fignifies the fame as the Latin *con*, together, and *γναθος*, a jaw. It is given to this fifh from that remarkable ftructure of its mouth, by which the jaws are made to grow together, and the very end of the mouth only opens.

SYNGNOME, Συγνωμη, in rhetoric, the fame with *conceffion*. See CONCESSION, *Cycl.*

SYNNAS, or SYNNADIUM *marmor*, in the writings of the antients, the name of a fpecies of marble ufed in the larger buildings of the Romans. It is by fome confounded with the docimenum marmor, with which the temple of Jupiter, erected by Adrian, was built; but this is erroneous, fince that elegant marble was always characterized as perfectly white, without blemifh; and this was always fpotted, and clouded with black, infomuch that fome writers have called it by an epithet, expreffing thofe variegations, *maculofa fynnas*.

SYNNEUROSIS, in anatomy, a kind of articulation of the bones, performed by the intervention of ligaments.

SYNOCHA, (*Cycl.*) in medicine, the name of a fpecies of fever, of which authors diftinguifh two kinds, the fimple, and the compound. The fimple *fynocha* is very rare in our parts of the world. The compound one is a mixed difeafe of the *fynochal* and ordinary continued fever, and has been called by fome the *putrid fever*, and *fynocha putrida* by the antient medical writers.

Signs of it. The *fynocha* always feizes people at once with a violent heat, without thofe fhiverings which frequently attend the firft attacks of other fevers. It is attended with a violent thirft, an univerfal languor, and laffitude of the limbs; and often with anxieties, fighings, and fuffocative difficulties of breathing. Acute and violent pains are felt in the head, with a tumid rednefs of the face and eyes, noifes in the ears, vertigos, and eternal reftlefsnefs and toffing about in the bed, with wildneffes in the thoughts. The urine from the firft is red and pellucid; it rarely admits of any breaking, or depofits any fediment before the fourth day, then it frequently precipitates a reddifh matter. There is generally an obftinate coftivenefs, and fpafmodic tenfions of the back and limbs are ufually very painfully felt during the whole time of the difeafe. The feventh day generally brings on a crifis in this difeafe, which in young people is ufually by an hæmorrhage of the nofe, in older by profufe fweats. The perfons moft fubject to this difeafe are thofe of a plethoric habit, who eat high-feafoned foods, and ufe little exercife; and efpecially fuch as have had any habitual evacuation of blood ftopt upon them. It is more frequent in the fpring and autumn, than at other feafons. *Junker's* Confp. Med. p. 267.

Caufes of it. Thefe are principally violent and unaccuftomed exercife, drinking large quantities of fpirituous liquors, long watchings, immoderate paffions, violent fweatings from hot medicines, and fudden cooling the body when very hot, by drinking large draughts of cold water, or other weak liquors. All thefe occafion the fever, by affecting the plethoric habit of the perfon; but this, which is the general and original bafis of the diftemper, is ufually brought on by omiffion of ufual bleedings at fpring and autumn, and other feafons, by fuppreffions of accuftomed hæmorrhages by the nofe, and by ftoppages of the menftrual, or hæmorrhoidal evacuations.

Prognoftics in it. The *fynochal* fever, in itfelf, is feldom attended with any great danger; and when the crifis happens by profufe fweats, or by an hæmorrhage, on the feventh day, there is no fear of any ill accidents: but if this time pafs without a crifis, and the congeftions remain, young perfons are ufually thrown into a violent phrenitis, and older ones into foporous affections; and even in fome cafes, where the crifis comes regularly on by hæmorrhages, there is danger from its being too great in quantity, and too much impairing the ftrength of the patient. There muft be great caution, however, ufed in affwaging this hæmorrhage, if that be found neceffary, fince, when it is imprudently done, it often brings on terrible obftructions in the vifcera, and hectics, dropfies, and cachectic complaints, that are very difficult to get rid of. The critical hæmorrhage is known to be coming on by a ftricture and itching of the nofe, an intenfe pain in the head, a rednefs of the eyes and face, and a ringing in the ears. Very frequently, alfo, the crifis is predicted by a remarkable perturbation of mind, but this is not the peculiar fymptom of the hæmorrhage, but happens as often, when it is by fweat. Often there is a dripping of blood from the nofe on the fourth day; and in this cafe, if nature be not difturbed, there will certainly be a farther bleeding on the feventh day. Complaints of an anxiety and uneafinefs about the breaft prefage an unhappy event. Other very bad fymptoms, alfo, are involuntary tears, great reftlefsnefs, no relief from fleep, and the appearance of livid, or brown fpots. The thick ftate of the blood, in this fever, makes it very eafily pafs into flow continued fevers and hectics; and fometimes, when the crifis does not come on at the feventh day, and there appear clouds in the urine, it appears afterwards on the fourteenth day.

Method of cure. Bleeding is always neceffary in the firft ftages of this fever, before the figns of coction appear in the urine; after this the violent emotions of the blood are to be quelled by nitrous and acid medicines, as the juice of lemons: to thefe muft be added reft, and a frequent drinking of warm and weak liquors. The bowels, if much bound, muft be gently loofened by an emollient clyfter; and after the crifis, fome gentle purgatives muft be given to clear the primæ viæ. Bleeding is not to be ordered after the figns of coction appear in the urine, for it often prevents the critical hæmorrhage, and renders the patient foporous, or delirious; and in the compound, or putrid *fynochal* fever, the patient is not to be blooded at all. Volatile falts are given by fome in this cafe, but very improperly, for they always are attended with mifchief, and often occafion cachectic tumors. Symptomatic quinfeys often attend this difeafe, and are to be relieved by gargarifms, rendered aftringent by an admixture of terra Japonica, or the like medicines; and in this particular cafe, wine is to be more cautioufly forbid than at other times. *Junker's* Confp. Med. p. 266.

SYNODON, in zoology, a name given by feveral authors to a fifh caught in the Mediterranean, and more commonly known by the name of *dentex*. *Aldrovand.* de Pifc. lib. 1. cap. 12. See DENTEX.

SYNODONTIDES, in natural hiftory, the name of a ftone defcribed by the antients, and faid to be taken out of the head of the fifh, called by them *fynodontes*, the *dentex* of the moderns. See DENTEX.

SYNONYMA. The perplexity in the writings of the antients, arifing from the ufe of *fynonymous*, as well as homonymous terms, is very great, when they ufe the fame word as the name of two different things. The whole value of the accounts they have left us is loft, by our not being able to diftinguifh which of the two they mean.

The great fource of this confufion has been in the love of fecrets in medicine, which prevailed as ftrongly among the antients, as it does among the moderns. In order to conceal the remedies they ufed, they often gave them new names, and often (which was worfe) ufed for them the names of other things.

Thus they called the pine-tree *itea*, the univerfally received name of the willow, and fo in many other inftances; from which we have, at this time, the fame word in ufe in different authors, as the name of different things.

Galen gives a prefcription for baldnefs, in which almoft all the ingredients are called by names wholly different from thofe that the reft of the world knew them by at that time, and by that means paffed upon the vulgar for new-difcovered medicines. The bay-tree is there called *ladonis*. The bear *amorphon brephos*, from the ftory of its young cubs being fhapelefs till licked into form by the mother bear. The ladanum, or labdanum, is called *apotragopogon*, becaufe of its being gathered from the beards of goats. And the adarce is called *pericalamitis*, from its being found concreted about a reed.

The compofition of Philo, called *cholice*, given in the fame author, is thus given in the ænigmatical manner by the fame means. The more learned and ingenuous people of thefe ages detefted this idle practice, and gave all things their common names; but as the abfurdities of one man will generally find followers in others of the fame ftamp, though the phyficians difcarded the practice, the fucceeding race of chemifts, famous for their love of fecrets, continued and improved it to fo great a degree, that were there writings of any value, it would be wholly impoffible, in many of them, ever to arrive at the author's meaning. See SYNONYMOUS, *Cycl.*

The Arabian writers have fallen more into the ufe of *fynonyms*, and that in a more erroneous manner than any other authors. If two things have happened to be called by the fame

fame name, be they ever fo different, they always defcribe them together, and attribute their virtues to one, as well as to the other; nay, they too often tranfcribe from other authors the virtues belonging to the one, and adding them to the account of the other, leave no room to trace out the truth, but by referring to the originals if they are in being. Thus thefe authors found the word *zarnich*, ufed by fome as the name of orpiment, and by others as the name of the lapis armenus, a blue colour, ufed in painting. Aëtius, and fome other authors, tell us, that the Syrians always ufed the word in this latter fenfe, though all other people ufed it in the former. Avifenna on this makes thefe two different fubftances, orpiment, and armenian zarnich, the fame; and having feen no lapis armenus, but what was of a greenifh blue, (as much of it was) he gives a chapter on zarnich, in which he tells us that it was of three kinds, yellow, red, and green: thus confounding the true fpecies of orpiment, the red and yellow, with a blue green colour, wholly different from them in its nature and qualities. In the fame manner the various fubjects of the vegetable world, that happen to have been at fome time called by the fame name by others, are always confounded by thefe writers. The chamælea, and chamæleon, two very different plants, both in figure and qualities, and which are not indeed wholly *fynonymous*, yet are confounded together, both by Serapio and Avifenna; and the nature and qualities of both defcribed fo conjunctly in one chapter, that they muft pafs for the fame plant with all, but thofe who have before made themfelves mafters of the hiftory of the materia medica of the earlier times, and are able to diftinguifh which of the characters and virtues belong to the one, and which to the other. The two ephemerons are in the fame manner confounded together by Avifenna, and blended in one chapter: and what is ftill more foreign than all thefe, the Ægyptian *lotus*, becaufe it happens to be called by the fame name with the *lotus* of the Greeks, which is a trifoliate plant, is defcribed together with it in the fame chapter, though nature can fcarce afford two plants more various, either in form, or qualities. And thus in numerous other inftances.

SYNONYMISTS, among the botanical writers, fuch as have employed their care in the collecting the different names, or *fynonyma*, ufed by different authors, and reducing them to one another.

SYNTENOSIS, a word ufed by anatomifts to exprefs an articulation of the bones when they are connected, as the offa fefamoidea of the toes, only by a tendon.

SYNTHENA, a term ufed by Paracelfus to exprefs an apoplectic, or epileptic diforder, attended with violent griping pains in the bowels. This is generally mortal.

SYNTHETIC, or SYNTHETICAL, (*Cycl.*) a term given to that part of chemiftry, which, after the analytical chemiftry has taken bodies to pieces, or reduced them to their principles, can, from thefe feparated principles, either recompound the fame body again, or, from the mixtures of the principles of one or more bodies in various manners, form a large fet of new productions, which would have been unknown to the world but for this art: fuch productions are brandy, foap, glafs, and the like.

Synthetical chemiftry, taken in the ftrict fenfe for the recompofition of bodies from their own principles, is rather of philofophical, than of ordinary ufe. This however is not eafy, except in a few cafes, nor are we to imagine, becaufe it may be done in fome, that nature has taken this way to compofe them; her method of compofition of bodies are a new fubject, and worthy a diligent inquiry. *Shaw's* Lectures, p. 169.

SYNTHETISMUS, a word ufed in chirurgical writings to exprefs the four operations neceffary to the reftitution of fractures, which are extenfion, coaptation, repofition, and deligation, or the bufinefs of bandage.

SYNTONUM *diatonum*, in mufic. See GENUS.

SYNTROPHIC, an epithet ufed to certain difeafes, which grow up with the patient. Of this kind is the epilepfy, which often firft feizes the perfon in infancy, and continues growing up with him, and increafing in ftrength as he does.

SYNULOTIC, a word ufed by fome writers in the fame fenfe as epulotic.

SYNYMENSIS, a word ufed by fome chirurgical writers to exprefs a conjunction of two bones by means of a membrane, as the bones of the finciput are connected to thofe of the forehead in young children.

SYPHAR, a word ufed by fome naturalifts in the fame fenfe as exuviæ, to exprefs the fkins which many reptiles caft off at certain times. Thus the fnake, the water newt, and all the caterpillar tribe, part with their fkins during the time they remain in that ftate.

SYRIACUS *lapis*, in natural hiftory, a name given by Aëtius, and many other authors, to the petrified fpines of the *echini ovarii*, called by us the *Jew ftones*, and *petrified olives*, from their likenefs to an olive in fhape, and called by the antients *tecolithus*.

It has been a common opinion, that this *ftone* was good againft the gravel and ftone; but Aëtius limits its efficacy to a particular cafe, which is that where the ftony matter is lodged in the kidneys and ureters; but he frankly confeffes, it is of no power to diffolve or break the ftone in the bladder.

This is contrary to the doctrine of Diofcorides, and the other old Greeks; but more confonant to reafon and experience. Some have carried its virtue fo far, as to pretend, that when rubbed to powder, and mixed in water, and that mixture rubbed on the groin and perinæum, it will break the ftones concreted within, and bring them away in pieces by urine. This, though too grofs for belief, is yet given us by Pliny. In moft of the common editions the words ftand thus, *lingentium frangit calculos*; but all the beft copies have it *ungentium*; and the word *lingentium* is only made by dividing the two perpendicular lines in the letter U.

SYRICON, a word ufed by fome authors in the fame fenfe as fandyx. Pliny makes it a compofition of equal parts of finopis and fandyx; and Aëtius gives it as the name of a collyrium, ufed in many diforders of the eyes.

SYRINGA, the *pipe-tree*, in botany, the name of a genus of trees, the characters of which are thefe. The flower is of the rofaceous kind, being compofed of feveral petals arranged in a circular form. The piftil arifes from the cup, and finally becomes a fruit adhering to the cup, of a turbinated form, and divided into four cells, which contain fmall feeds.

There is no other known fpecies of the *fyringa* befide the common one, and its variety, with double flowers. *Tourn.* Inft. Bot. p. 617.

Many fpecies of this flowering fhrub, common in gardens, are called *lilacs*. See LILAC.

In the Linnæan fyftem of botany, *fyringa* is the name of a feparate genus of plants, the characters of which are, that the flower cup is a perianthium formed of only one leaf, which is fmall, tubulated, and erect, and has four notches at its extremity. The flower is a fingle petal, formed into a very long and flender tube, divided at the extremity into four fegments, which are fpread open and bent; the feveral jags, or fegments, being ftrait, hollowed, and obtufe. The ftamina are two very fhort filaments, terminated by fmall antheræ, hid within the tube of the flower. The piftillum is compofed of an oblong germen, a thready ftylus of the length of the ftamina, and a thick and bifid ftigma. The fruit is an oblong, compreffed, and pointed capfule, containing two cells, and made up of two halves, containing each a fingle, oblong, and compreffed feed; pointed at each end, and furrounded with a membranaceous rim. *Linnæi* Gen. Plant. p. 3.

The feveral fpecies of this beautiful and fweet flowering fhrub are eafily propagated, by taking off their fuckers in autumn, of which they always produce great plenty. Thefe fhould be tranfplanted intu the nurfery, where, after they have remained two years, they will be fit to be removed to the places where they are to remain. They are very hardy, and may be planted in almoft any foil or fituation; and require no farther culture, but to take away the fuckers, and cut out the dead wood every year, and now and then to dig up the earth about their roots. They flower in May and June. *Miller's* Gardner's Dictionary.

SYRINGITES, a ftone mentioned by Pliny, and defcribed as being always full of cavities. Some have fuppofed this author meant the ofteocolla by this name; but it is more probable, that he meant the ftone we now call *fyringoides*, or the pipe-ftone.

SYRINGOIDES *lapis*, the *pipe-ftone*, in natural hiftory, the name of a very beautiful foffile fubftance, of which there are feveral different kinds. The *tubuli marini*, or cafes of fea worms, lodged in any folid fubftance of the foffile kind, conftitute what is called the *lapis fyringoides*.

The moft frequent kind is made of the common matter of the ludus helmontii, or feptaria, with tubuli of different kinds and dimenfions in it; but the moft beautiful fort is that made of the bottoms of fhips, old boards, or piles of wood; which having been long in the fea, have been pierced by the fea worms, which have made their feveral burrows, and left their fhells behind in them: the whole of thefe fubftances becoming afterwards petrified, is found in form of wood, with all the knots, veins, and other characters, but wholly of the hardnefs of ftone. This is ufually of a blackifh colour, and the pipes being of a pale yellow, the whole makes a very elegant appearance.

Our clay-pits about London afford alfo a *fyringoides* of this kind, but the earth there abounding with the matter of the common vitriolic pyrites, that fubftance by degrees gets into the pores of the wood, and the whole feems a mafs of pyrites with thefe pipes lodged in it in different directions. This has been called by authors *pyrites fyringoides*. *Hill's* Hift. of Foff. p. 64.

SYRINGOTON, in furgery, an inftrument to lay open fiftulæ. We have a propofal of a *fyringoton*, of a new form, for laying open fiftulæ in ano, by Mr. Freke. See Appendix to *Barroughby's* Tranflation of *Aftruc* on the Fiftula in ano.

SYRINGOTOMY, in surgery, a term used for the cutting for a fistula.

SYRITES, in natural history, a name used by some for the sapphire, but by Pliny for a stone, which he says was generated in the bladder of a wolf.

SYRIUS, a word used by some authors for a very strong purge, a preparation of scammony, being no other than a resin, or magistery of that drug.

SYRMA, among the Romans, a long garment, common to both sexes, that reached to the ground. It was used in tragedies, that the persons of the heroes and heroines might appear the taller. *Pitisc.* in voc.

SYRMÆA, a name given by the antients in general to a certain root, said to be of the radish kind, and to be frequently used to provoke vomiting.

Some have made it also the name of a sort of viand, prepared of honey, the fine fat of animals, and other ingredients, which was the prize bestowed at one of the Spartan games: others have used it to express a purging potion made only of salt and water, or plain brine. The Ægyptians frequently purged themselves with this radish juice and salt, which operated gently both upwards and downwards, and these potions were called by the same name *syrmæa*.

SYRMÆA, Συρμαια, in antiquity, was used as a designation of the games at Sparta, the prize in which was συρμαια, or a mixture of fat and honey. *Potter*, Archæol. Græc. Tom. I. p. 431.

SYRMÆSMUS, a word used by the antient medical writers to express a gentle purging of the stomach or bowels, either by stool or vomit. It had its name from *syrmæa*, a word expressing a medicine that acted in this gentle manner.

SYRTITES, in natural history, is used by some authors as the name of a gem of a very beautiful appearance, in the substance of which are interspersed faint stars of a saffron colour. *Hofm.* Lex. Univ. in voc.

SYRUPS (*Cycl.*)—There seems to be no part of pharmacy, in which the writers of dispensatories have more erred, than in their directions about the making of *syrups*; which seems the more strange, because this part is particularly easy. The misfortune is, that great men cannot stoop to consider common and ordinary things; whence, however, the credit of a physician may sink in the esteem of those, who by their employments are led to a knowledge of these ordinary things.

The whole of the business of *syrup*-making may be, however, reduced to a few short and easy rules. As first, it is matter of experience that aqueous infusions, decoctions, or other aqueous liquors, require twice their own weight of dry sugar-candy to make them into a *syrup* of a just consistence, for keeping without candying or fermenting.

This rule, by directing the use of sugar-candy, fixes the consistence of *syrups* in an exacter manner than any way else, because all salts require a determinate proportion of water in crystallizing; so that sugar, in the form of candy, contains always one certain proportion of water, while different kinds of sugar may hold more or less aqueous matter, according to their different manner of refining, the accidents of the weather, &c. Hence, therefore, all such infusions for *syrups* as are of a delicate, or destructible colour, which is impaired by boiling, such as violets, clove July flowers, &c. and all such infusions as contain any volatile parts, which would evaporate by a boiling heat, as those of cinnamon, orange peel, &c. should have twice their own weight of sugar added to them, and be kept close covered in the gentle heat of a balneum mariæ, till the sugar is dissolved; which, to hasten the solution, should be reduced to powder.

Secondly, the decoctions of all such vegetable substances, as lose no valuable parts by boiling, may be boiled down to the proper consistence with their own weight of sugar, the two being first clarified together with the whites of eggs in the usual way: but if the ingredients here contain any unctuous, or balsamic parts, whereon their medicinal virtues depend, let the sugar be added from the very first, and boiled along with the ingredients; afterwards straining and clarifying it, before it be of near the consistence of a *syrup*. This rule is founded on the property in sugar of dissolving resins and oils, so as to make them intimately mix with water.

Thirdly, all vegetable juices are to be thoroughly purified, before they are boiled into *syrups*. Thus the juices of lemons, oranges, &c. are first to be filtered, and then made into *syrups* without boiling, according to the first rule: but the juices of mulberries, and the like, will not clarify without a beginning fermentation; wherefore they must first stand a day or two, and then they will pass through a flannel; after which these are to be made into *syrup* with an eighth part less than twice the quantity of sugar; that is, with one pound twelve ounces of sugar to a pint of the juice, on account of their being somewhat saccharine themselves. And wines, and vinegars, must be made into *syrups* with the same quantity. *Shaw's* Lectures, p. 205.

Pectoral SYRUPS, *syrupus pectoralis*, a new form of medicine prescribed in the late London Pharmacopœia, and intended to stand in the place of the *syrup* of maiden-hair, and some others of that kind. It is to be made thus: take leaves of English maiden-hair dried five ounces, liquorice four ounces, boiling water five pints; steep the ingredients for some hours, and afterwards strain off the liquor; and when it is made clear by settling, add to it the necessary quantity of sugar to make it a *syrup* in the common way. *Pemberton's* Lond. Disp. p. 299.

SYRUP *of saffron.* See SAFFRON.

SYRUS *lapis*, a name given by the writers of the middle ages to a fossil, seeming to be the same with the *thyrreus* of Pliny; of which name this indeed seems only a corruption, according to the barbarous manners of those times. There are many remarkable qualities recorded of this, one of which is, that it would swim on water. Hence it seems to have been a species of bitumen; but we want a fuller description.

SYSSARCOSIS (*Cycl.*)—Besides the use of this word to signify a kind of articulation of the bones, by means of flesh, when the muscles are extended from one bone to another; it is also used by some chirurgical writers to express a method of curing wounds of the head when the cranium is laid bare, and the interstice between the lips of the wound too wide for a contraction, by means of promoting the granulation, as it is called, or growth of new flesh. Paulus Ægineta uses it also to express a preternatural generation of flesh about the vessels and coats of the testes, which is sometimes the case in a sarcocele.

SYSTASIS properly only denotes the consistence of any thing, as of a syrup or ointment, but authors have used it also in a different sense. Hippocrates understands by it a collection of humors about the palate; and sometimes expresses by it a contraction of any part of the body from an uneasiness, or sensation of pain.

SYSTEMATICAL *qualities*, a term used by Mr. Boyle to express such qualities as are also called *cosmical*, and do not depend on the nature and constitution of the body itself, but on its being a member of this general system of the universe, in which capacity it is acted upon by agents unperceived by us, which occasions great changes in it.

SYSTEMATISTS, in botany, those authors, whose works in this science are principally employed about the arranging plants into certain orders, classes, or genera. *Linnæi* Fund. Bot. p. 2.

SYSIMBRIUM, *water-mint*, in botany, a name given by some to a species of mint. See MENTHA.

SYSTREMMA, a word used by Hippocrates to express a collection of humors forming a hard tumor, or tubercle, in any part of the body; called also sometimes *systrophe*.

SYSTYLE, in architecture, that manner of placing columns where the space between the two fusts consists of two diameters, or four modules.

T.

T, in the Italian muſic, ſtands for *Tutti*, all or altogether. See the article TUTTI.

It is alſo uſed to mark the tenor, and has the words *primo*, *ſecundo*, or the figures 1°. 2°. added, to ſignify the firſt or ſecond tenor.

The letters T, *t*, or *tr*, are often uſed likewiſe to ſignify a ſhake or trillo, to be made on any ſound, and are placed over the note on which the ſhake is to be made; thus  or  being an abbreviation of the word *Trillo*. See the article TRILLO.

TABACUM, in botany, a name by which John Bauhine, and ſome others have called the tobacco-plant, more uſually known among authors by the name *nicotiana*. See the article NICOTIANA.

TABARZET, a word uſed by ſome writers to expreſs highly refined ſugar.

TABAXIR, and *Arundo* TABAXIFERA, names by which ſome authors call the Bamboo cane. *C. Bauhin.* Pin. p. 18.

TABERNA *Meritoria*, among the Romans, Mars's hoſpital, or a place where diſabled ſoldiers were maintained at the charge of the government. *Danet.* in voc.

TABES *Dorſalis* (*Cycl.*)—This diſtemper, according to a late author, is a particular ſpecies of conſumption, the proximate cauſe of which is a general debility of the nerves.

Of the ſeveral kinds of conſumptions incident to human bodies the *Tabes dorſalis* is the ſloweſt in its progreſs, but the moſt melancholy in its circumſtances; and, unleſs timely obviated, for the moſt part fatal.

This diſeaſe is incident only to young men of ſalacious diſpoſitions; and proceeds from too early venery, an immoderate uſe of it, or pollutions.

It ſeems therefore to derive its origin from too frequent venereal ſpaſms. And the immoderate loſs of the ſeminal fluid, has alſo a conſiderable ſhare in producing the effect.

The ſymptoms of the *Tabes dorſalis* are involuntary, nocturnal ſeminal emiſſions, a pain in the back, and often in the head; formication in the ſpine, an aching pain, rolling, and hanging down of the teſticles, a weakneſs of memory and ſight, and a mucous diſcharge from the urethra, eſpecially after ſtraining at the diſcharge of the excrements. The mucous diſcharge here mentioned, is called by Hippocrates *liquidum ſemen*; but it is no more than the mucus of the proſtate gland. This diſeaſe is farther attended with great melancholy and dejection of mind; and a gutta ſerena often follows. The eyes grow hollow, the viſage meagre and thin; the body emaciated and weak, a palpitation of the heart, and ſhortneſs of breath ſucceed; with a concourſe of hectical complaints, ending in death.

For the cure of this diſtemper, a regularity of the non-naturals is of the utmoſt importance. Good air, rather cool than hot, is of great uſe. As to diet, high-ſeaſon'd meats, ſpirituous and fermented liquors, ſhould be avoided. No food is ſo beneficial as milk: Chocolate alſo is eſteemed, in ſuch quantities as to ſit eaſy on the ſtomach. Animal food of eaſy digeſtion at dinner, does no harm. Suppers ſhould be avoided, at leaſt milk only ſhould be then taken, about two hours before going to bed. Sleep muſt be little, and in due ſeaſon; that is, the patient ſhould go to bed and riſe early. Indulgence in bed in a morning is hurtful. The general rule ſhould be, to riſe immediately upon waking; which, though irkſome at firſt, will by cuſtom be made familiar and agreeable. Moderate exerciſe, or ſo much as the patient's ſtrength will admit of without wearineſs, ought to be uſed. Some recommend riding, eſpecially a long journey, by ſuch daily portions as to avoid extraordinary fatigue. The ſecretions of the body, if out of order, ſhould be regulated: And the patient ſhould be entertained with chearful company. As to medicines, the claſſes of balſamics and aſtringents are chiefly uſeful. Among the latter, the Peruvian bark, either in ſubſtance, extract, or tincture, the acid elixir of vitriol, and the *tinctura ſaturnina* or *antiphthyſica*, are the moſt efficacious. Strengthening plaſters may alſo be laid on the loins; and, chief of all, the cold bath ſhould be uſed. See Pract. Eſſay on the *Tabes dorſalis*, Lond. 1748.

TABON, in natural hiſtory, a name given by the people of the Philippine iſlands to a bird called in other places *daie*, and remarkable for the largeneſs of its eggs; though ſome accounts of theſe are certainly fabulous. See the article DAIE.

TABULARIUM, among the Romans, the name of that part of the treaſury where the Elephantine books were kept. See the article ELEPHANTINE, *Cycl.*

TABUM, a word uſed by medical writers, to expreſs a thin ſanious and putrid humour, flowing from old ulcers, or from mortified parts, in caſes where the vital powers are not ſufficient for the generation of a perfect or concocted matter.

TACET, in the Italian muſic, is often uſed to denote a long reſt, or pauſe. It uſually ſignifies that a whole part is to lie ſtill: thus, *Chriſte Tacet*, *depoſuit Tacet*, intimates that while one or more parts are performing the *Chriſte*, or the verſe *depoſuit*, &c. the part marked *Tacet* ſhould be ſilent. *Broſſ.*

TAC-*Free*, in old charters, an exemption from payments. *Blount.* Law Dict. in voc.

TACHAS, in ichthyology, a name given by ſome authors to the manati, or ſea-cow. See the article MANATI.

TACIT *Decree*, in Roman antiquity, ſecret deliberations, to which none but old ſenators were ſummoned.

J. Capitolinus mentions a decree of this ſecret kind, which he calls *S. C. tacitum*, and ſays, that the uſe of them among the antients was derived from the neceſſities of the public, when upon ſome imminent danger from enemies, the ſenate was either driven to ſome low and mean expedients, or to ſuch meaſures, as were proper to be executed before they were publiſhed, or ſuch as they had a mind to keep ſecret even from friends; on which occaſions they commonly recurred to a *Tacit decree*, from which they excluded their clerks and ſervants, performing that part themſelves, leſt any thing ſhould get abroad. *Capitol.* de Gordian. c. 12.

In the early times of the republic there are ſeveral inſtances mentioned by hiſtorians, of ſuch private meetings of the ſenate, ſummoned by the conſuls to their own houſes; to which none but the old or proper ſenators were admitted, and of which the tribunes uſually complained. Vid. *Dion. Halic.* L. x. 40. L. xi. 55, 57. *Middlet.* of Rom. Sen. p. 90.

TACK, in a ſhip, a great rope having a wale-knot at one end, which is ſeized or faſtened into the clew of the ſail; ſo is reefed firſt through the cheſſe-trees, and then is brought through a hole in the ſhip's ſide. Its uſe is to carry forward the clew of the ſail, and to make it ſtand cloſe by a wind: And whenever the ſails are thus trimmed, the main-*Tack*, the fore-*Tack*, and miſen-*Tack*, are brought cloſe by the board, and haled as much forward on as they can be.

The bowlings alſo, are ſo on the weather-ſide; the lee-ſheets are haled cloſe aft, and the lee-braces of all the ſails are likewiſe braced aft. Hence they ſay, a ſhip ſails or ſtands cloſe upon a *Tack*, i. e. cloſe by the wind. The words of command are, *Hale aboard the Tacks*, i. e. bring the *Tack* down cloſe to the cheſs-trees. *Eaſe the Tack*, i. e. ſlacken it, or let it go, or run out. *Let riſe the Tack.* i. e. let all go out.

The *Tacks* of a ſhip are uſually belayed to the bitts, or elſe there is a chevil on purpoſe to faſten them.

TACKLE (*Cycl.*)—*Burton*-TACKLE, in a ſhip. See the article BURTON.

Gunners-TACKLE, in a ſhip, that which ſerves to hale the ordnance in or out.

Winding-TACKLE, in a ſhip, a *Tackle* that ſerves as a pennant, with a great double block and three ſhivers in each, ſeized faſt to the end of a ſmall cable about the head of the maſt; it has a guy brought to it from the fore-maſt. Into this block is reeved a hawſer, which is alſo reeved through another double block, having a ſtrap at its end; which being put through the eye of the ſlings, is locked into it with a fidd, in order to hoiſt in goods.

The fall of this *Tackle* is reeved into a ſnatch-block, and ſo is brought to the capſtan, whereby the goods are heaved.

TACOMAR-*Tree*, a name by which ſome authors call the fugar-cane. *Marggrave*, p. 829.

TADPOLE. The animal called by this name is no other than the frog in its firſt ſtate from the ſpawn; and this creature furniſhes the curious in microſcopic obſervations with a beautiful view of the circulation of the blood, eſpecially when young. See Tab. of Microſcopical Objects, Claſs 1.

The method of procuring them for this purpoſe in the greateſt perfection, is this: Let a ſmall quantity of frog's ſpawn be kept for ſome days in water, and from this will be produced a vaſt number of young *Tadpoles*; theſe, while very young, are perfectly tranſparent, and when placed before the double microſcope, the heart may be eaſily ſeen, and its pulſation regularly obſerved; and the blood protruded thence may be beautifully ſeen circulating through the whole body; but particularly in the tail, where tho' ſo very minute, more than fifty veſſels may be ſeen at one view. The young brood grow more and more opake every hour, and in a day or two the circulation of the blood can only be ſeen in their tail, or in the fins near the head. *Baker*'s Microſcope, p. 126.

TADOMA, in zoology, a name given by many authors to a ſpecies of duck, called by others *vulpanſer*, and in Engliſh the *ſhell-drake*, or *burrow-duck*; and by ſome the *bergander*.

It is of a middle size between the duck and goose; its beak is broad, short, and red; and at the origin of the upper chap there is a large red tubercle of flesh. The head and upper part of the neck are of a mixed blackish and greenish colour, very glossy and shining; the rest of the neck is white; the breast and shoulders are of an orange-colour, which makes a sort of ring surrounding the whole anterior part of the body. The lower part of the breast and belly have a black broad line reaching to the anus; the rest of the breast and belly are white; as are also the under sides of the wings, but just below the tail there is a faint cast of the orange colour. The middle of its back is white. The shoulder-feathers falling on each sides of the back are black, and the wings are almost wholly white, only some of the longer feathers are black. The tips of most of the tail-feathers are also black. Its legs and feet are of a pale red, and their investient skin so thin, that the veins may be seen under it. They are common on the coasts of Lancashire, and build in deserted rabbit-holes; but their flesh is not well tasted. *Ray*'s Ornithol. p. 279.

TÆDA, in pharmacy, a term used by some authors to express certain compositions made up in form of troches. These are sometimes meant as pessaries to be introduced into the vagina, and therefore made into this form; sometimes they are compositions of fragrant or other ingredients for fumigations.

TÆDA, in botany, a name given by some authors to the pinaster or common wild pine or mountain pine. *J. Bauhin*, Vol. I. p. 253.

TAEL, an East-Indian weight, being the sixteenth part of a *cati*, See the article BAHAR.

TÆNARIA, Ταιναρια, in antiquity, a festival in honour of Neptune, surnamed *Tænarius*, from *Tænarus* a promontory in Laconia, where he had a temple. *Potter*, Archæol. Græc. T. I. p. 432.

TÆNARIUM *Marmor*, the name of a marble used by the antient architects and statuaries. There were two kinds of it, very different in colour, but perfectly agreeing in hardness, and in the high polish they were capable of. The first or most frequent kind was black, and was dug from the promontory called *Tænarus*, in the Lacedæmonian state; the other, which was more scarce, and much more beautiful, was of a green colour with a cast of yellow; this was dug in the Tagetan quarries, and was called by some *marmor herbosum*, and *xanthon*. *Strabo*.

TÆNIA, (*Cycl.*) in ichthyography, the name of a fish of the anguilliform, or eel-shaped kind, common in the Mediterranean sea, and brought to market in Italy, and elsewhere.

It is a very remarkable little fish, being of a pale flesh colour with a slight admixture of blue, and is free from scales; and its flesh so transparent, that the vertebræ of the back may be easily counted through it. Its body terminates in a long and very slender tail. The mouth is small, and has one row of sharp teeth in each jaw, and is very singular in that the belly-fin is twice as wide as the back one; and runs so far up to the head, that the anus which is situated at its termination, is very near the angle of the under jaw. The intestines are all covered with a silvery peritonæum, which is seen also plainly through the flesh. It is commonly of a foot long, and not more than a finger's breadth. *Willughby*'s Hist. Pisc. p. 116.

There are two other species of this fish. See the articles FALX, and CAVIRAGO.

TÆNIA *Cornuta*, the *horned Tænia*, in ichthyology, a name given by many authors, to the species of cobitis, named by Artedi, the cobitis with a forked prickle placed under each eye. This fish is properly a species of the cobitis. *Schonfeldt* Hist. Pisc. See the article COBITIS.

TAGETES, *African Marygold*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the radiated kind: Its disk is composed of floscules divided into several segments, and its outer edge of semifloscules; all standing on embryo seeds, and contained in a one-leaved cup of a tabulated form. The embryos finally become seeds of an angular form, furnished with a foliaceous head, and affixed to the thalamus of the flower. There are also some species in which the flower is wholly composed of semi-floscules.

The species of *Tagetes*, enumerated by Mr. Tournefort, are these: 1. The great upright *Tagetes*, with single pale yellow flowers. 2. The great upright *Tagetes*, with very large double flowers. 3. The smaller Indian *Tagetes*, with a single flower, commonly called the single African, or French marygold. 4. The smaller Indian *Tagetes*, with double flowers. 5. The small Indian *Tagetes*, with a double reddish yellow flower. 6. The middle-sized Indian *Tagetes*, with a double yellow flower. 7. The Indian *Tagetes*, with a single fistulous flower. 8. The Indian *Tagetes*, with a double fistulous flower. 9. The least Indian *Tagetes*, with a velvety flower. 10. The *Tagetes*, with extremely finely divided leaves. *Tourn.* Inst. p. 488.

We have a great many species of this plant annually raised in our gardens, for the beauty of their flowers. They are propagated by sowing the seeds in spring, on a moderately hot bed; when the young plants come up, they must have air allowed them; and when three inches high, they should be removed to another hot bed, which should be arched over with hoops that it may be sheltered with mats. They are to be planted here at about eight inches distance, and when they are grown stronger, as about the beginning of May, they are to be taken up with a ball of earth about their roots, and placed where they are to remain; or else at eighteen inches distance in a nursery, where when they flower the finest sorts may be marked and removed, with a large ball of earth to their roots, either into pots, or into the borders of the flower-garden. They are very beautiful; but their smell is very offensive. *Miller*'s Gardener's Dict.

TAGLIATO, in the Italian music, is used for a measure called by the French *Barré*; that is, when the character of common time is thus marked  with a perpendicular line drawn down through its middle. It signifies a pretty quick motion, and contains a breve, or its quantity in smaller notes, in each bar. Hence it is called *Alla breve*.

TAJACU, in zoology, the name of an animal common in some parts of America, and called by many authors *aper moschiferus*, or the musk-boar.

It is of the shape of our hog, but much smaller, and has no tail, and its head is broader, and the snout much less pointed than in our hog; the neck is short and thick, and the whole body of a grisly colour or mixture of black and grey. Its body is covered with hairs, much thicker and stronger than our hogs bristles, something like the bristles of the hedgehog, and like them also variegated with circles of black and white; these are four or five fingers breadth long on the back, and gradually diminish to the sides; on the middle of its head between the ears it has a sort of crest, made up of black bristles; its ears are small and erect. and its eyes small; its snout, feet and hoofs, are just like those of the European hog; but the two posterior or exterior hoofs are longer than in any other of the cloven-footed beasts.

What is most singular however, in this creature, is a certain gland which he has upon the back, and which has given occasion to some to say its navel was placed there. This gland is situated on the very ridge of the back near the rump, and is so closely covered with long bristles, that till they are removed by blowing, and keeping them back with the hand, the gland is not to be seen; when these are removed there is seen a spot almost naked, in the middle of which the top of the gland is seen; the lips of this gland usually stand a little way above the flesh, and its aperture easily admits a large stylus; and this gland, when lightly pressed, spews out a liquid substance of a brownish yellow colour, and very sweet scent, something like that of musk or civet. The gland itself is placed between the skin and flesh, and is not wholly covered by its constringing muscle, but only surrounded by it at its bottom. *Ray*'s Syn. Quad. p. 120.

TAIIBI, in zoology, the name of an American animal, described by Marggrave and other authors, and supposed by some to be only the male of the Opossum. The Portuguese in America call it the *Cachorro de mato*, and by the Dutch it is called *Boschratte*.

Its body is long, its head shaped like that of a fox, its nose sharp, and it has whiskers like those of a cat; its eyes are black and prominent, and its ears roundish, soft, tender, and white. The tail near its insertion has white hairs, and toward the extremity black ones, and near the end is naked of hair, having a skin like that of a snake over it. *Ray*'s Syn. Quad. p. 183.

TAIL (*Cycl.*)—TAILS *of Fishes*. This part in the fish kind is the subject of very great distinctions, among the characters of the several genera. It differs in the several kinds of fish in a very obvious manner, in number, situation, and figure.

In regard to the first difference, the *acus lumbriciformis*, and one of the kinds of the *serpens marinus*, have no *Tail* at all; in all other fishes there is a *Tail*, and it is never more than one on each fish.

In regard to situation, there is this great difference, that in some it is placed perpendicularly, in others horizontally. In almost all the known fishes it is placed perpendicularly, except in the dolphin, the phocæna, the orca, the manati, and all the whale kinds; for in all these it is placed horizontally, when the body is laid in its natural posture.

In figure it has many very remarkable differences, which are of great use in ichthyological distinctions. 1. In some fish it is rounded at the end; as in the cottus, and some others. 2. In some it is cut off even as it were at the end, so that the whole *Tail* is a sort of parallelogram; as in the tench, and some of the salmons. 3. In some fishes it is cuspidated at the end, as is the case in the conger, the eel, and the petromyzon. 4. In others it has as it were a small segment of a circle cut out at the end, and so is slightly hollowed out; this is the case in the carassius, and some of the salmons. 5. In many fish it is forked or opened into two points, making an acute angle; this is the figure of the *Tail* in the pearches, the cyprini of many kinds, &c. 6. Finally, the *Tail* is falcated in many fish, that is, it is of the shape of a crescent; as in the sword-fish, the tunny, mackrell, and the like. *Artedi*, Ichthyolog.

TAIL, in the manege. Many affirm that the dock of a horse's *Tail* serves to point out his sixth or seventh year; saying, that about the time that the black speck, or eye of the bean begins to disappear, and the cavity to be filled, the dock of the tail becomes longer, by reason that the vigour of the young years begins to abate; and nature has not strength enough to nourish and keep up the joints or knots that form the dock; so that when the horse is six years old, one of these joints slackens, and begins to fall down; and a year after, another descends in like manner. But this relaxation or down-falling happens sooner in some than in others, according as they have been well or ill kept, with reference to feeding, housing, and working. Accordingly we find the marks of a horse's age, taken from his *Tail*, are so erroneous, that we see a great many jockies maintain, that the first joint descends when he is nine, and the second when he is ten years old.

TAILS *of Comets*. We have an enquiry into the cause of the *Tails* of comets by Mr. Euler in the Mem. de l'Acad de Berlin, Tom. 2. p. 117. seq. He thinks there is a great Affinity between these *Tails*, the zodiacal light, and the aurora borealis; and that the common cause of them all is the action of the sun's light, on the atmospheres of the comets, of the sun, and of the earth. He supposes that the impulse of the rays of light on the atmosphere of comets, may drive some of the finer particles of that atmosphere far beyond its limits; and that this force of impulse combined with that of gravity towards the comet, would produce a *Tail*, which would always be in opposition to the sun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, must vary the position and figure of the *Tail*, giving it a curvature, and deviation from a line drawn from the center of the sun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and that the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be so great, that the force of the sun's rays may produce a new *Tail*, before the old one can follow; in which case the comet might have two or more *Tails*. The possibility of this is confirmed by the comet of 1744, which was observed to have several *Tails* while it was in its perihelion. See the article ZODIACAL *Light*, and AURORA *Borealis*.

TAIPARA, in zoology, the name of a Brasilian species of perroquette. It is of the size of a lark, and of a pale green colour over its whole body; its tail is short, not reaching beyond the tips of the wings when closed. Its beak is red, and its legs are grey. Near the origin of the beak it has a semilunar red spot on the head, and a yellow spot in the middle of each wing. It builds in the deserted abodes of ants on trees. *Marggrave's* Hist. Bras.

TAINHA, in zoology, a name given by some to a species of mullet caught in the American seas, and more usually called the *curema*. *Willughby*, Hist. Pisc. p. 277. See the article CUREMA.

TAL, a name used by some writers on the materia medica to express the dung of peacocks; and by some of the chemical writers, for any alkali salt.

TALA, in botany, a name by which some authors call the plant whose seed is the sesamum or oily purging grain of the shops. *Herm.* Mus. Zeyl. p. 58.

TALABONG, in natural history, a name given by the inhabitants of the Philippine Islands to a species of heron, common among them; which is much smaller than our heron, and perfectly white all over.

TALÆDITES, Ταλαιδιτης, in antiquity, gymnical exercises in honour of Jupiter ταλαιος. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 432.

TALARIUS *Ludus*, among the Romans, a game somewhat resembling our dice-playing, and performed with a kind of gold or ivory dice, which they shook as we do in a box, before they threw them. There was this difference, however, between their game and ours, that our dice have six sides, because they are cubical; but theirs had but four, and were conically shaped. They made use of them for divination, as well as playing; and they concluded upon a good or evil augury, according to what came up. As they usually threw four of them at a time, the best chance was when four different sides came up. The sides were called by the name of some animal, as the dog, vulture, basilisk, *&c.* Or of some deity, as Venus, Hercules, *&c.* Some authors have been of opinion, that they were marked with the forms of animals, or images of Gods, and not with numbers or dots, as our dice are. *Danet*. in voc.

TALASSIO, among the Romans, an acclamation used at marriages; for the origin of which see *Pitisc.* and *Danet* in voc. and *Livy* 1. 9.

TALC, (*Cycl.*) in natural history, the name of a large class of fossile bodies. See Tab. of Fossils, Class. 1.

The *Talcs* in general are defined to be fossils, composed of broad, flat, and smooth laminæ or plates, laid evenly and regularly on one another; easily fissile, according to the site of these plates, but not all so in any other direction; flexile and elastic; bright, shining, and transparent; not giving fire with steel, nor fermenting with acid menstrua, and sustaining the force of a violent fire without calcining.

By these characters, the *Talcs* may be distinguished from all other bodies which resemble them; and, according to their several natural and essential differences among one another, they are themselves divided into two separate orders, and under those into four genera.

The *Talcs* of the first order are those composed of plates of great extent, each making singly the whole horizontal surface of the mass.

Those of the second order are those composed of small plates, in form of spangles, irregularly disposed, and usually many of them concurring in different directions, to the formation of one of the surfaces of the mass. *Hill's* Hist. of Foss. p. 71.

The genera of the first order are two: The first is of those composed of visibly separate plates of extreme thinness, and each fissile again into a number of others yet finer. The *Talcs* of this genus are called *speculares*.

The second genus is of those which are composed of separate plates of considerable thickness, and those not fissile into any thinner. The *Talcs* of this genus are called *hyalinæ*.

The genera of the second order are also two. The first is of those composed of small plates, in form of spangles, each fissile into many yet finer and thinner ones. The *Talcs* of this genus are called *bractearia*.

The second genus is of those composed of small plates in form of spangles, which are moderately thick, and are either not fissile at all, or are only so to a certain degree, or into a small number of others yet thick ones, and those no farther fissile. The *Talcs* of this last genus are called *elasmides*.

Authors have hitherto been used to call also another set of bodies by the name of *Talcs*, with the addition of the adjective *fibrose*; but as these are found not at all of the nature of the true *Talcs*, they are now distinguished by the name *fibrariæ*. See the article FIBRARIÆ.

Authors are divided as to the origin of the word *Talc*. Lemery derives it from the High-Dutch *Talch*, tallow, because it feels greasy. But this is improbable; since Avisenna, who had no commerce with the Germans, uses the word, and tell us, that the aster of Lemnos is *Tallz*, which cannot be calcined but with the most intense fire, and which is dangerous when taken inwardly. Its origin therefore, according to Mr. Pott, seems rather *Arabic*. Cæsalpinus tells us, that *Talc*, among the Moors, signifies *star*, and that they understand thereby the *stella famia*. Johnson also says the word is Arabic, signifying small shining stars. This term does not occur among the antients, as Theophrastus, Dioscorides, or Pliny; tho' some critics pretend that Dioscorides designed it by *stella terræ*. Cæsalpinus and Salmasius endeavour to prove that *Talc* is the *aphroselene* or *selenites* of Dioscorides. Those authors also pretend that Pliny meant the same thing by *schistus*. Cæsalpinus refers *Talc* to the *galeucos argyrodamanti similis*; and Bœtius to the *argyrodamas* itself. Some think that a passage in Pliny, Lib. xxxvi. c. 22. may be understood of *Talc*. Avisenna call it *lapis lunæ*; and Albertus Magnus, *aphroselene*. The most common species in Germany is called *katzen-silver*, or *katzen-glimmer*. It is also named from a particular place where it is found, *Kiphauser-glantz*. When it is of a yellow colour, they call it *katzen-gold*, and in Latin, *mica*, and *chærile nitidum*. In some places it is also called *sper-glass*. *Pott*. in Mem. de l'Acad. de Berlin.

Talc is often confounded with similar concretions, as with the *schistus* or *lapis fossilis*, with the *spathum* or *spatum*, and *gypsum*, Muscovy-glass, or *glacies-Mariæ*, and the *lapis specularis*. Boyle takes it for an alkaline spathum, and others for other substances, from which nevertheless it differs. See *Pott*. in Mem. de l'Acad. de Berlin, 1746.

The repeated experiments of the chemists, who expect great things from an oil of *Talc*, have abundantly proved that this substance is indissoluble both in acids and alkalies in a liquid, form; and the most violent corrosive mineral acids, such as spirit of nitre and aqua-fortis, and the like, make no change in it. Mr. Du Hammel, in his *topiarium hermeticum*, indeed speaks very largely of a solution of *Talc* made by means of a long trituration in water alone: This, he says, in six hours will reduce *Talc* into an unctuous or oily fluid. And in the Commercium Literarium for the year 1732, there is a paper in which it is affirmed, that *Talc* may be in part dissolved by the mineral acids, particularly by spirit of salt; and that the dissolved *Talc* may be afterwards precipitated from the menstruum; but, in reality, neither the fuming spirit of salt, nor the purer acid of salt, dried by a repeated solution and sublimation, with sublimate Mercury, exerts the least effect upon this refractory substance. It has been also said, in the Memoirs of the Paris Academy, that *Talc* and oil of vitriol produce alum; but neither is this found true on experiment; much less is any solution of *Talc* to be expected from the volatile spirit of vitriol, the spirit of naphtha, or oil of wine, so much recommended by some of the chemists for this purpose. The greater part of these pretences are absolute frauds, intended only to impose on credulous persons, who expect great matters from an oil of *Talc*; the others are probably owing to the error of taking other foliated bodies for *Talc*, such as the plated spars, which easily split into flakes like *Talc*, and are soluble in any acid.

The burning *Talc* and sulphur together does not advance any thing

thing farther toward a folution of the *Talc*: Even after repeated trials of this, the *Talc* is only changed to a fort of afh-colour, which is owing to the impurity of the earth contained in the fulphur. This is to be underftood of the pure and genuine *Talc*, fuch as that of Mufcovy, commonly called ifinglafs; for the black and yellow kinds of *Talc*, after repeated calcinations, will be finally diffolv'd in concentrated aqua-regalis, or in very ftrong fpirit of falt, into a yellow liquor refembling the folutions of gold. This colour, in the folution, has given fome perfons idle notions of its containing gold or folar fulphurs, as they exprefs themfelves; but an accurate examination fhews, that this colour is only owing to fome attenuated particles of iron; and upon evaporation of the folution, there remains a mere crocus martis. If frefh aqua regalis be continued to be poured on this yellow *Talc*, it will draw ftill more of a yellow tincture from it, till the remaining matter be perfectly white, retaining no remains of its golden appearance.

Common fire has very little efficacy upon *Talc*, it neither making it crepitate, nor melt, nor reducing it to the condition of gypfum or lime: All the change it can make in it, is the rendering it in fine fomewhat more brittle, and in part deftroying its foliated ftructure. It fuffers no diminution all this time in weight, and is as bright and lucid, and as unctuous to the touch afterwards as before. Angelus Sala had *Talc* kept forty days in a glafs-houfe fire, and at the end of that time took it out unaltered: But according to the experiments of Neuman and Hoffman, the folar fire, concentrated by powerful burning-glaffes, melts this ftubborn fubftance into a greyifh kind of glafs. Thus we may eafily conclude, that when Morhoff and the great Boyle talk of reducing *Talc* into a kind of gypfum in a common fire, in the fpace of an hour, they deceived themfelves, and ufed fome other fubftance which had the appearance of *Talc*, but was not fo; fuch is the plated felenites, which cannot be diftinguifhed from the pureft ifinglafs, till it is tried, by bending its feparated plates, thefe being not at all elaftic, as thofe of *Talc* are.

The action of falts rendered fluid by fire is much more powerful upon *Talc* than any of thefe before-mentioned fubftances; but to this purpofe the fire muft be very violent, the common fire of fufion producing nothing; hence it is, that authors in general have not found the effect of this procefs; for they affirm that *Talc*, in a ftrong fire, mixed with three times its own quantity of a fufile falt, fuffers nothing, but renders the fame appearances afterwards as before. Neuman alfo affirms, that he had ufed nitre, borax, and the corrofive falts in the fame manner, without the leaft fuccefs: But Mr. Pott gives a different account of fuch proceffes, which he tried not with the common fire of fufion, but with the higheft degree he was able to give.

In his trials with this violent heat, *Talc*, fated with a folution of a cauftic alkali, run into a lax and fpungy mafs. Mixed with half its quantity of a purified alkaline falt, it run into an opake and blackifh mafs. *Talc* calcined in a common furnace, and then mixed with half its weight of an alkali, melted and run into a hard and ftony mafs of a brownifh black, which was capable of the fine polifh of an agate; and on repeating the fame experiment afterwards, the mafs produced by it was of the fame hardnefs and denfity, but perfectly white as alabafter; the colour was in many other trials found to be in great meafure owing to the cleannefs of the crucible, and to its containing no ferrugineous or other metalline or mineral matter. Kunkell has before obferved, that *Talc* mixed with falt of tartar, and with fritt, and put into the fire, eafily runs into glafs with the fritt, without any greater degree of fire than what is always ufed on this occafion: But Mr. Pott obferves that *Talc*, with an equal quantity of hepar fulphuris, does not run into a compact mafs, but rifes in foam and fpume to the top of the crucible, and acquires a yellow colour, and the mixture afterwards fuffers the greateft fire that common *Talc* can bear, unhurt. *Talc* does not detonate with nitre, becaufe it contains no fulphur, but they afterwards vitrify together in a violent fire; and this has been before obferved in the German ephemerides. *Talc*, mixed with an equal portion of fixed arfenic, runs into a white hard mafs; and with double its quantity of Glauber's falt, it does not diffolve, but only becomes a white friable mafs, yellowifh on the furface. *Talc*, with equal parts of borax, runs in a violent fire into a tranfparent mafs, refembling the gem called the *aqua marina*; and melted with different mixtures of borax, nitre, and arfenic, it runs into vitreous maffes, of many different degrees of colour.

Talc is ufed with great fuccefs in the diftillation of acid fpirits; that of falt is always naturally impure, and can fcarce be rendered pure but by an admixture of a *talcy* earth in the retort.

The mixture of *Talc* with different kinds and quantities of glafs, may be fuccefsfully performed with a violent fire, but not with a fmaller degree: Thus three parts of *Talc* with one part of cryftalline glafs, make only a fpongy and friable mafs in a common fire; but in a more violent one they become a firm and folid mafs of a brown colour. Minium, or glafs of lead, mixed in equal quantities with *Talc*, and fet in a violent fire, run into a yellowifh glafs refembling the opake pieces of amber; and two parts of minium to one of *Talc*, produce a clear and tranfparent yellow glafs, which is of a hardnefs capable of giving fire with fteel. The alkaline earths, mixed with *Talc*, produce a mafs fcarce vitrifiable by any fire: Hence appears the reafon why copels made of lime and *Talc* are fo very hard to vitrify. Minium added to thefe mixtures makes them combine into a firm mafs, but without perfect fufion; but borax added to them melts them readily into a true glafs. The gypfous earths mixed with *Talc*, will not unite into a mafs in any degree of fire; but if borax be added, the *Talc* readily melts. Thus two parts of *Talc*, two parts of that fpar or gypfous matter called *glacies mariæ*, or the common plated fpar, with one part of borax, run into a yellow mafs refembling a topaz.

The argillaceous earths do not vitrify with *Talc*, but they run into a mafs of great hardnefs, which will give fire with fteel, and is very ferviceable to make crucibles of, thefe veffels not fuffering the glafs of lead to run thro' them. *Talc*, joined with the vitrifiable ftones, forms no remarkable body, but the mafs remains friable; but from thefe maffes, by the addition of proper matters to render them fluid, great variety of elegant compounds may be made. Thus *Talc* mixed in equal quantities with powder of flints, on adding to the whole a fourth part of cryftal glafs, the whole unites into an opake but folid white mafs. Alkali falt added in equal quantity to *Talc* and flint, gives a tranfparent yellow glafs; and white fand, *Talc*, and a fixed alkali, in equal quantities, afford a green glafs; with other mixtures of this kind, in different quantities, the refemblances of many beautiful ftones are produced; and what is very remarkable, fome grains of metalline matter are often found on the furface of the maffes.

Cæfalpinus, Aldrovand, and fome others affirm, that *Talc* melted with copper, or added to copper, while in fufion, gave it a white colour; this being taken for granted, authors have hence agreed that *Talc* contains an arfenical earth. But experiment fhews this to have been a falfe affertion, in regard to *Talc*; and probably it only owes its origin to the cant language of fome of the alchemifts, who have called the flowers of zink, *Talc*; tho' thefe alone muft render copper yellow, not white. Antimony and *Talc*, firft calcined with nitre, run in a violent fire into a fort of flint, which will give fire with fteel. With regulus of antimony and the black flux, it runs into a black mafs; and with bifmuth it calcines into a grey powder. So little is there in the propofals of the chemifts for the metallization of *Talc* by antimony and bifmuth. Mem. de l'Acad. de Berlin, Ann. 1746.

In what part of Mr. Boyle's works the learned author from whom the foregoing extract was taken, has found that *Talc* may be reduced by common fire to a gypfum in an hour, we know not; but we find that Mr. Boyle fays, that the calcination of *Talc* is fo very difficult, that eminent chemifts have looked upon calxes of *Talc* as counterfeits. Works abr. vol. 1. p. 160.

Mr. Boyle mentions the extracting of gold from *Talc*, as having fometimes fucceeded. See Works abr. vol. 1. p. 160. but *vide fupra*.

The mountains in Hungary and Germany many of them abound in the Mufcovy *Talc*, not inferior to the *Talc* of that country from whence it has its name. The mountain of Cliffuro, which is a part of mount Hæmus, as alfo mount Pyrlipe, fhine like filver in all parts both day and night, provided there be any moon.

The *Talc* in thefe hills is the only occafion of this. There are alfo *Talc* rocks near Spittal in Upper Carinthia; and many other hills are faid alfo to contain great quantities of it; but there is a fort of felenites fo very like this *Talc*, that people are eafily deceived by its appearance. This felenites fplits into flakes like the *Talc*, but they are brittle. *Brown*'s Travels.

Mexico TALC. There is a famous cave fome leagues from Mexico, on the north-weft fide of the city, beyond the lake, the top and fides of which are faid to be lined with leaf gold; but that of fuch a kind, that the common methods of fluxing the ores have no effect upon it. The Spaniards, after many trials, have given it over, but are ftill perfuaded by the Indians that it is gold, and that the famous Montezuma obtained a great part of his treafures from this cave. The leaves, as they are called, are no more than fpangles of the fize of a man's nail; and the account we have of it in the Philofophical Tranfactions, and the various methods attempted in vain to reduce it to metal, abundantly prove that it is only a yellow *Talc*. Vid. Phil. Tranf. N°. 39.

Mufcovy TALC, a kind of foliaceous body, well known by the Englifh name of ifinglafs. See the article SPECULARIS *Lapis*.

Philofophic TALC, a name given by fome of the chemical writers to the flowers of zink.

This fubftance, diffolved in vinegar, affords what they have in their unintelligible language called, oil of *Talc*, and extolled as a thing of vaft power in the fixing of Mercury, and many other imaginary operations; and befide this, they call it a fovereign remedy for all difeafes.

The chemifts of after ages, feeing fuch prodigious effects afcribed to oil of *Talc*, and not conceiving that *Talc* was a mere

mere cant word in this place, have been at infinite pains, by means of a thousand differently varied menstruums, to obtain an oil from the common Venetian *Talc*, a dry stone which in a very remarkable manner resists the force of all menstrua, and of fire; and from which therefore no oil can be obtained. In the various operations used to this purpose, some have really hit upon liquors of a considerable power; but that power has been wholly owing to the menstruums they employed, not to the stone; and even if it were, could have none of the effects of the oil of *Talc*, mentioned by these dark writers, who meant by it so very different a substance as a solution of these flowers, which are only, that till of late little understood metal, zink, in another form. See *Oil of* TALC, infra.

Venetian TALC, in the materia medica, the name of a fossile substance famous among the chemists for the great things they have expected from the oil of it, if that could ever have been obtained; and among the ladies of Italy, and the neighbouring nations, as a cosmetic, when reduced to an impalpable powder after repeated calcinations, by levigating on a porphiry.

It is of an extremely irregular, though in some degree plated or foliaceous texture, and is remarkably smooth and soft to the touch, of a lax and somewhat crumbly texture; the several moleculæ it is composed of cohering but slightly, either in themselves, or with one another. It is of several sizes, from one inch to five or six in diameter; and in colour, of a pale silvery grey, with a large admixture of green. In many of the coarser parts of this substance, it may be observed to have a great analogy with the common French chalk, or morochthus. It is dug in several parts of Italy, and is brought to us principally from Venice, whence it has its name. *Hill*'s Hist. of Foss. p. 76.

Oil of TALC, the name of a substance, which has given great trouble to the chemists of later ages.

It had been recorded by some old writers, that oil of *Talc* had the power of fixing silver, that is, giving it the weight and tenacity of gold, so that it should no longer be distinguishable as silver, nor soluble in aqua fortis, but only in aqua regia, as gold. This was all idle and imaginary, no known substance having any such power. Our chemists of later times, supposing this oil was to be obtained from Venetian *Talc*, a common flaky stone, have tortured it a thousand ways to extract this divine liquor from it, but in vain; for unhappily this is a stone remarkable beyond almost all other bodies, for suffering almost nothing by any menstruum, nor even by fire itself. Some have however compounded liquors with the pompous names of oil of *Talc*, from their preparations of this stone; but these have owed all their qualities to the menstruums employed in making them, not at all to the stone; nor indeed had they owed them to that, would they have had any relation to the oil of *Talc* they were seeking after. The inventors of that barbarous term having never thought of Venetian *Talc*, or any other stone under the name of *Talc*; but given that name to the fibrose and cottony flowers of Zink, which in some degree resemble the disunited filaments of the fribrariæ, or, as they are called by the vulgar, fibrose *Talc*.

When zink is dissolved in distilled vinegar, and the solution distilled again in a cucurbit, there is first drawn over an insipid phlegm; after this there arise some fibrose white flowers; and finally these melt down into a sulphureous liquor, which is inflammable like spirit of wine. This being poured into a phial of water mixes with it, only leaving a few drops of a fragrant and aromatic oil swimming on the surface; this floating liquid is the so famed oil of *Talc*; but this is properly no preparation of zink, or its flowers, but merely the essential oil of the vinegar employed in the solution; and it is easy to conclude from this, that this so famed liquor can possibly have no title to any of the wondrous qualities ascribed to it. Mem. Acad. Scienc. Par.

TALED, in the Jewish antiquities, a sort of habit that the Jews wore, chiefly when they repeated their prayers in the synagogue. *Numbers* xv. 38. *Deuteronomy* xxii. 12.

It served instead of that square garment they wore heretofore, to which Moses had appointed that they should fasten borders of blue to the four quarters, and fringes or ribbands all along the borders. But at present, that they may not be exposed to the laughter of the people for the too great singularity of their dress, they content themselves with wearing a square piece of cloth underneath, with four tufts at the four corners, and when they meet in the synagogue to say their prayers, they cover their heads with a square woollen veil, which has four tufts at its four corners. It is this they call *Thaled*, or *Taled*. *Calmet* Dict. & *Leo of Modena*, Ceremonies of the Jews, P. I. ch. 5, II.

TALLY (*Cycl.*)—TALLY *the Sheets*, at sea, a word of command, when the sheets of a main-sail, or fore-sail are to be haled aft. See the article SHEETS.

TALPA, (*Cycl.*) the *Mole*, in the Linnæan system of zoology, makes a distinct genus of animals; the characters of which are, that they have feet with five claws on each, as well on those behind as on those before; and have their fore-feet made like hands, and fitted for digging. *Linnæi* Syst. Nat. p. 37.

This, though a very common animal, is very little observed by the generality of the world. Its fur is very short, soft and thick. Its nose is like that of a hog; and its teeth like those of the *mus araneus*, being single and eminent on the sides of the upper jaw, and those farther within the mouth armed with many points. It has scarce any neck, its head seeming set between its shoulders. Its legs are very short, its claws very sharp, and its toes five in number on each foot; the inner part or sole of the fore-feet is very broad, and much resembles the palm of the human hand. Its claws on these are more robust and strong, than in any other animal of its size: The whole feet and toes are not placed downward but sideways, for the sake of the creature's continual employment in digging, it being properly a subterranean animal. Its tail is short, and hairy.

It has been supposed by many, that the *Mole* had no eyes; and others have affirmed, that it had eyes, but that they were covered with a membrane; but neither of these assertions are true. The eyes are small, and have apertures in the skin, through which they may easily be discerned by a curious observer; and are very black, about the size of a millet-seed, and fastened to a nerve.

The reason they have not been observed by the common people, is, that they are hid by the fur; but, on blowing that away, they always shew themselves. It has no ears.

Its skin is extremely firm and tough, so that it requires a sharp knife to pierce it.

This seems the care of nature to defend the creature from the cold; and the fineness of the fur, that is, the smallness of every hair, seems proportioned to the small pores they had to grow out of. *Ray*'s Syn. Quad. p. 234.

TALPA, in surgery, a name given by some authors to an encysted tumor, situated under the scalp. *Heister*'s Surgery, p. 324.

TALWOOD, *Taliatura*, in our old writers, fire-wood cut and cleft into billets of a certain length: It is otherwise written *Talghwood*, and *Talshide*. Stat. 34 & 35 Hen. VIII. c. 3. 7 Edw. VI. c. 7. 43 Eliz. c. 14. *Cowel.*

TAMALAPATRA, in the materia medica, a name by which some authors have called the *folium Indum*, or Indian leaf, used in medicine. *C. Bauhin*, Pinax. p. 409.

The tree which produces this leaf is one of the *Enneandria monogynia* of Linnæus; and of the *arbores fructu calyculato*, of Mr. Ray. It is a large and lofty tree, the flowers and fruit of which resemble the cinnamon-tree. Its leaves, when full grown, are ten inches or more in length; and six or eight, in breadth. The flowers stand in clusters, in the manner of umbels on the tops of the branches, and are of a greenish white colour. The fruit is of the bigness of our currant.

The antients recommended *Indian-leaf*, as stomachic, sudorific, and cephalic. At present, it is utterly disregarded, being only kept in the shops as an ingredient in several compositions. Vid. *Hill*, Hist. Mat. Med. p. 419. seq.

TAMANDUA, in natural history, a creature called in English the ant-bear; and by the Brasilians *Tamandua-guacu*.

This animal has its English name from its feeding on ants, and having its hinder feet like a bear's. It has a very long and sharp snout, and its tongue is slender, and extensible to a very great length; and it has a long and brushy tail. *De Laët*, Ind. Occ. L. 16. c. 15.

The principal food of the *Tamandua* is ants, which he catches by scratching open their subterranean hives, and thrusting his long tongue into them; when the ants are gathered in great numbers upon this, he draws it back and eats them; and this he repeats till he is satisfied.

His tail serves him for a sort of cover; and he can, upon occasion, spread it almost over his whole body. *Barlæus* de Reb. Bras. p. 223.

TAMARIND, *Tamarindus*, in botany, the name of a genus of trees; the characters of which are these: The flower is of the rosaceous kind, and is composed of several petals, arranged in a circular form. The cup consists of one leaf, divided into many segments at the edge; and from this arises a pistil, which finally becomes a flat pod, containing in it another, in which are several flatted and angular-shaped seeds. The interstice between the two pods is filled up with a soft pulpy substance.

The only known species of this tree is that which produces the common *Tamarind*, the pulp of which is used in medicine. *Tourn.* Inst. p. 660.

The characters of this genus of plants, according to Linnæus, are, that the calyx is a plain four-leaved perianthium, the leaves of an oval figure, and equal in size. The flower is composed of three petals, which are of an oval figure, somewhat plane and flat, but folded and gaping open; these are smaller than the leaves of the cup, and are inserted in them, leaving a vacant space at the bottom of the cup. The stamina are three filaments, which have their origin together in the cavity in the cup, and are pointed, and bent toward the petala of the flower. The antheræ are single: The pistil has an oval germen. The style is pointed, and bent toward the stamina; and its stigma is single. The fruit is a long pod, of a compressed shape, and covered with a double skin between

between which is the pulp; it consists of only one cell. The seeds are angular, and of a flatted figure; and are three in each pod. *Linnæi* Gen. Plant. p. 9.

We owe the knowledge of the use of *Tamarinds*, in medicine, to the Arabians. The antient Greeks knew nothing of them; and Serapion, Mesue, and Avicenna, are the first authors who prescribe them.

The fruit of the *Tamarind* which is what we use, is only the pistil of the flower swelled into a pod; this is greenish at first, but grows brownish or reddish, as it ripens; its common size is four inches in length, and one in breadth; and it is undulated on the back, and deeply notched in three or four places at the front, which is terminated by a large rib, which runs from the pedicle on which it grows, to the end of the pod, and there frequently terminates in a sort of hook.

This fruit is, properly speaking, composed of two pods, the one inclosed within the other; the outer pod is fleshy, and of the twelfth of an inch in thickness when fresh, and the inner one is thin as a fine piece of parchment; between these two there is an intermediate space of about a quarter of an inch all the way; and this space is filled up with a very soft and pulpy substance, of a tart but very agreeable taste, which is what we use in medicine. This is blackish and of a viscous texture, and is traversed by three large vessels, or rather bundles of vessels, one of which runs all along the back of the pod, and the two others are placed on the opposite side, and often there are several ramifications of vessels, which run off different ways from these. These vessels carry the vinous juice, which afterwards hardens into the viscous matter of the pulp; but this is not all their office, for they also convey nourishment to the seeds in the inner pod.

We use the *Tamarinds* only in medicine; but the Africans, and the People of many of the Oriental nations, where they are common, make them into a sort of confect with sugar, which they eat as a delicacy, and which cools them in the violent heats of their climates; and at the same time keeps their bowels in a proper state of laxity. The four taste of this fruit proves, that acid particles abound greatly in it, and a chemical analysis of it gives farther proof of this. There is indeed no alkali to be obtained fom *Tamarinds*, otherwise than by distilling them in a retort with quick-lime. A simple analysis of them yields no other principles but acid and sulphur. Six pounds of *Tamarinds* mixed with six pints of water, will yield six drams of essential salt; this however requires a long time to crystallize, not fixing itself to the sides of the vessels under two months standing; in all this time however the liquor never grows mouldy, as such liquors usually do; and it in this somewhat resembles tartar, or the essential salt of grapes, which never separates itself from their juice under a very long time. Indeed, to be assured of gaining all the essential salt of any plant, the liquor ought to be covered half an inch deep with oil, to prevent its spoiling, and suffered to stand a whole year unmoved in the same vessel. The salt of *Tamarinds* in all things resembles cream of tartar; it is sharp to the taste, and will not dissolve in cold water. It does not detonate on the fire, nor yield any vinous smell, when moistened with oil of tartar. *Tamarinds* dissolved also in common water, and set in digestion for several months, yield on distillation only an acid spirit, like that from vinegar.

It is not uncommon in those places where *Tamarinds* are frequent, to find an essential salt crystallized on the branches of the tree, this greatly resembles cream of tartar in all respects, and is no other than the genuine salt of the plant formed by the sun's drying up the accidentally extravasated juices; nor is this peculiar to this tree alone, but many others are at times found with their juices thus extravasated, and their salts thus crystallized by the heat. The leaves of that large species of maple, which we vulgarly but improperly called the sycamore, are often in hot seasons found thus covered with crystals of their essential salt which is sweet, and very much of the nature of sugar; and the lime-trees have their leaves often covered with a like saccharine matter, which being washed off from them and the liquor given any person to drink, is found to have the taste and the purgative virtue of manna. Mem. Acad. Par. 1699. See the article TAMARINDS, *Cycl.*

TAMARISCUS, the *Tamarisk-tree*, in botany, the name of a genus of trees; the characters of which are these. The flower is of the rosaceous kind, being composed of a number of petals, arranged in a circular form; the pistil arises from the cup, and finally becomes a capsule, resembling that of the willow of a long figure and membranaceous structure, and containing seeds winged with down. *Tourn.* Inst. p. 661.

The species of *Tamarisk*, enumerated by Mr. Tournefort, are these: 1. The shrubby thick-leaved *Tamarisk*, called the German *Tamarisk*. And, 2. The tall arborescent fine-leaved *Tamarisk*, called the French *Tamarisk*.

It is a very remarkable property of this tree, that its salt made in the way of other lixivial salts is no alkali, but a mere sal salsus. The salt of guaiacum also approaches to the nature of this.

TAMATIA, in zoology, the name of a very strange bird of the Brasils. It is of the *Gallinula*, or moor-hen kind, but very different from the European birds of that genus. Its head is very large, its eyes large and black, its beak is two fingers breadth long, and one broad, shaped somewhat like a duck's, but pointed at the end; its upper chap is black, its under one yellow; its legs are long, and the thighs in great part naked; its toes are long; its tail is very short. Its head is black, and its back and wings of a plain dusky brown. Its belly is of the same brown, variegated with white. See Tab. of Birds, N°. 44. *Marggrave*'s Hist. Brasil.

TAMBOS, in Peruvian antiquity, buildings placed at certain distances for the lodging of the princes of that country, in their travels through their dominions. See Mr. de la Condamine, in Mem. de l'Acad. de Berlin, Tom. 2. p. 435. who tells us (p. 438.) that he saw several remains of these *Tambos*, in his journey from Quito to Lima.

TAMNUS, in botany, the name of a genus of plants, called by the old writers *Bryonia nigra*, and from them in English black bryony.

The characters of this genus are these: The flower consists of one leaf fashioned like a bell, open at the mouth, and divided into several segments. Some of these are steril, or male flowers, having no embryo; and others fruitful or female flowers, having in their center an embryo, which afterwards becomes a berry, usually of an oval figure, and covered with a sort of hood of a membranaceous structure; this berry is full of roundish seeds. This is a climbing plant, as well as the white bryony, but it has none of the tendrills which that has.

The species of this genus, enumerated by Mr. Tournefort, are these: 1. The clustery *black bryony*, with small yellowish green flowers. 2. The *black bryony*, with a larger white flower. 3. The American *black bryony*, with leaves like those of the citrul. *Tournefort*, Inst. Bot. p. 102.

TAMOATA, in zoology, the name of an American fresh-water fish, called by the Portuguese *Soldido*.

It is a small oblong fish, with a flat head, somewhat like that of a frog Its mouth is small, and from each angle of it there hangs a long single filament, by way of a beard. It has no teeth, and its eyes are extremely small. It has eight fins; two at the gills of one finger in length, and hard and firm like horns; two on the belly, of a softer substance; and one on the middle of the back, another near the tail, and another small one opposite to it on the belly: Its tail is the eighth. Its whole head is covered above with a hard coat like a shell; and its body with a sort of coat of mail made up of oblong hard squamose bodies, dented at their edges. Its colour is a sort of rusty iron colour. It is accounted a very well-tasted fish. It lives only in fresh-water rivers; and it is said, when the water where it is dries up, it will crawl out upon the land, and go in search of more. See Tab. of Fishes, N°. 34. *Marggrave*'s Hist. Brasil.

TAMPOE, in natural history, the name of an East-Indian fruit, approaching to the figure of the Mangoustan, but not near so agreeable to the taste. This fruit is very much of the size, shape, and colour of some of our common summer apples; but its skin is very thick and tough, and it has no crown. The Indians eat it in places where better fruits are scarce, and in some places call it the Mangoustan.

TAN (*Cycl.*)—*Flowers of* TAN. Flower of *Tan* is a name given by the people employed in the tanning-trade, to a yellow substance, often found upon old *Tan*, or oak bark broken to pieces, which has been used as *Tan*, and is of no farther service.

The name, however, is very improper; and though every body conversant in *Tan*-yards must have seen the thing, yet it has always passed as an efflorescence of the bark, till the curious Mr. Marchand enquired more accurately into its nature, and found it to be a plant of itself, wholly different from the matter of the *Tan*; and to which the bark which had been often wetted and dried again, served as a proper matrix. He found it to be more nearly allied to the spunge, than to any other genus of plants, and therefore named it *spongia fugax mollis flava & amæna in pulvure coriario nascens*, soft, beautiful, yellow fading spunge, growing on *Tanners* bark.

It makes its appearance most frequently in the summer months, and is then seen in small tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at first in form of a thin yellow scum, and is of a sort of jelly-like structure; but it every day grows larger and thicker, till it stands above half an inch out from the surface of the bark. As it grows, its surface becomes more and more cavernous and spungy, the pores or holes being of different diameters, and the interstitial matter forming a sort of net-work more or less regular, and often interrupted by irregular prominences in several parts; and, in fine, when the growth is compleat, the whole more resembles a spunge, than any other vegetable substance, and is of a deep yellow colour, and considerably thick and tough consistence; there are no roots to be discovered issuing from it; its smell is like that of rotten wood, and its taste is somewhat styptic. It always appears in the warm months, and always upon such old *Tan* as has begun to ferment, and is in the state in which our gardeners use it for hot-beds. If it happens to stand exposed to the south sun, it is but of short duration; but if it be in a sheltered place, it will last a considerable time, and often spread itself to a great

extent, and make a very beautiful figure for many weeks. Mem. Acad. Par. 1727.

TANACETUM, *Tanzy*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, conſiſting of numerous ſmall floſcules, which are divided into many ſegments at the ends, are placed on the embryo ſeeds, and are contained in a ſort of ſcaly cup, of a ſemi-orbicular figure. The embryos ripen into ſeeds, which have no down adhering to them. To this it is to be added, that the flowers are collected into large cluſters.

The ſpecies of *Tanzy*, enumerated by Mr. Tournefort, are theſe: 1. The common yellow-flowered garden *Tanzy*. 2. The garden *Tanzy* with curled leaves. 3. The garden *Tanzy*, with the leaves and the ſmell of mint, called by authors, *corymbiferous mint*, and *coſtmary*. *Tourn.* Inſt. p. 461.

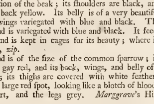
The leaves of the common *Tanzy*, either dried and given in decoction, or the expreſſed juice of them taken, are excellent in nephritic and hyſteric caſes. The good women in the country give the juice with great ſucceſs againſt worms, and in the colic. The infuſion of the dried plant is a remedy againſt flatulencies and colics, and is given in dropſies, and in ſuppreſſions of the menſes, and of the urine. It is pretended by ſome, that the diſtilled water deſtroys worms; but this is leſs probable.

TANGARA, in zoology, the name of a Braſilian Bird, of which there are two ſpecies: The firſt is of the ſize of the green-finch, and is of a fine ſhining ſea-green on its head and neck; and has a black ſpot on the front of the head, juſt above the inſertion of the beak; its ſhoulders are black, and the reſt of the back yellow. Its belly is of a very beautiful blue, and the wings variegated with blue and black. The tail is broad, and is variegated with blue and black. It feeds on vegetables, and is kept in cages for its beauty; where its only note is *zip*, *zip*.

The ſecond kind is of the ſize of the common ſparrow; its head is of a fine gay red, and its back, wings, and belly of a fine deep black; its thighs are covered with white feathers, and have each a large red ſpot, looking like a blotch of blood; the tail is ſhort, and the legs grey. *Marggrave*'s Hiſt. Braſil.

TANGARAC, a poiſonous Braſilian plant; but the root, ſays Piſo, is an antidote to the leaves, flowers, and fruit. *Boyle*, Works abr. vol. 1. p. 14.

TANGENT (*Cycl.*)—The definition of a *Tangent*, commonly given, is mentioned by Mr. Chambers; but it does not extend beyond the conic ſections; for in curves of higher orders a line may both touch and cut. A general definition is therefore neceſſary. As a right line is the *Tangent* of a circle, when it touches the circle ſo cloſely, that no right line can be



drawn through the point of contact between it and the arch, or within the angle of contact that is formed by them; ſo, in general, when a right line ET touches any arch of a curve, as EH in E, in ſuch a manner that no right line can be drawn through E, betwixt the right line ET and the arch EH, or within the angle of contact HET, that is formed by them, then is ET the tangent of the curve at E. *Maclaurin*'s Fluxions, Art. 181.

The *Tangent* of an arch is the right line that limits the poſition of all the ſecants that can paſs through the point of contact, though, ſtrictly ſpeaking, it is no ſecant. Ibid. Art. 505.

As to the methods of inveſtigating *Tangents* by Fluxions, ſee the ſaid treatiſe, book I. c. 7. where it is demonſtrated independently of infiniteſimals.

To determine the *Tangents* of curves, ſuppoſed to be deſcribed by the interſections of right lines revolving abour given poles. See Mr. *Maclaurin*'s Fluxions, Art. 210. ſeq.

In finding the tangents of curves by the method of infiniteſimal differences, it has been objected, that the concluſion is found by a double error. 1°. By taking the curve for a polygon of an infinite number of ſides. 2°. By the falſe rule for taking the differential of a power. But there is no need of ſuch ſuppoſitions in the method of fluxions, for it may be geometrically demonſtrated, that the fluxions of the baſe, ordinate, and curve, are in the ſame proportion to each other, as the ſides of a triangle reſpectively parallel to the baſe, ordinate, and *Tangent*. When the baſe is ſuppoſed to flow uniformly, if the curve be convex towards the baſe, the ordinate and curve increaſe with accelerated motions; but their fluxions at any term are the ſame as if the point which deſcribes the curve had proceeded uniformly from that term in the *Tangent*. Any farther increment which the ordinate or curve acquires, is to be imputed to the acceleration of the motions with which they flow. See *Maclaurin*'s Fluxions, Book. 1. chap. 7 and 8.

Any two arches of curve lines touch together, when the ſame right line is the *Tangent* of both at the ſame point. But when they are applied to each other in this manner, they never perfectly coincide, unleſs they be ſimilar arches of ſimilar and equal figures.

TANNERS *Bark*. This is a ſubſtance of prodigious uſe in gardening; and is the bark of the oak-tree chopped and ground into a ſort of coarſe powder, for the dreſſing of ſkins, after which uſe it becomes of ſervice to the gardener. Its fermentation is very laſting and very equal; hence it is the moſt valuable of all things for the making of hot-beds; and when it has ſerved to this uſe, and is thoroughly rotted, it makes a very valuable manure for land, one load of it doing as much ſervice as four loads of dung.

It has not been of very long uſe in England, and was brought to us from Holland in the reign of King William, and then uſed for the raiſing of orange-trees; but after this period it became diſuſed; and it is of a much later date that it has been brought into uſe again for the raiſing the pine-apple, ſince which time it is become generally uſed, wherever it is to be had, for all the purpoſes of the hot-bed, in raiſing tender plants.

There are ſeveral ſizes of this *tan*, and they heat in a different manner in proportion to their ſize, the ſmalleſt heating much quicker, and cooling again in a ſmaller time; and the largeſt acquiring its heat more gradually, but keeping it much longer. The ſkilful gardener therefore muſt uſe one or the other of theſe, or a mixture of both, according to the ſeveral occaſions he wants them for.

It ſhould always be taken within a fortnight after it comes out of the pit, and laid up in a round heap for a week, to drain out the moiſture; after which it ſhould be formed into a bed, and ſhould be laid at leaſt three feet thick. A hot-bed, properly prepared, of this ſubſtance, will retain a moderate heat ſix months. *Miller*'s Gardener's Dict.

TANNING (*Cycl.*)—The operation of *Tanning* is performed, on leather, better in the Weſt Indies than in England. They uſe three ſorts of bark, the mangrave bark, the olive bark, and another; and the whole buſineſs is ſo ſoon done, that a hide delivered to them is in ſix weeks ready to be worked into ſhoes, though they beſtow leſs labour than we do. Phil. Tranſ. N°. 36.

Every part of the oak-tree, of what age or growth ſoever, is fit for the tanners uſe, and all oaken coppice-wood, of any age or ſize, being cut and procured in barking-time, will tan all ſorts of leather, at leaſt as well as the bark alone. When this material is got at the proper ſeaſon, it muſt be very well dried in the ſun, more than the bark alone; thence it is to be cut up, and preſerved in a covered place for uſe.

When it is to be uſed, the greater wood muſt be firſt cleft ſmall, to fit it for the beating and cutting engine; and the ſmaller muſt be put into the engine as it is. Which done, it muſt be again dried upon a kiln, and after that ground in the ſame manner that the tanners grind their bark. Such wood as is to be uſed preſently after 'tis gotten, will require the better and the more drying upon the kiln; and if this is omitted, it will blacken and ſpoil all the leather it is uſed about. Where oak is ſcarce, black-thorn will tolerably well ſupply its place; and where that is not to be had in ſufficient plenty, the white thorn will do. Phil. Tranſ. N°. 108.

Birch alſo, being ordered in the ſame manner with oak, is fit for ſome uſes in *tanning*, particularly it does very well for *tanning* of ſhoe-ſoal leather. All theſe ingredients will *tan* much better than bark alone, and that with much leſs charge; ſo that this diſcovery may very well ſave the felling of trees when the bark is wanted, at a ſeaſon when the ſap is up, which, when 'tis done, cauſes the outſides of the trees to rot and grow worm-eaten; whereas if the trees had been felled in winter, when the ſap is down, they would have been almoſt all heart, as the people expreſs it, and not ſubject to worms. This manner of uſing the wood with the bark, in *tanning*, will alſo increaſe the value of underwoods very conſiderably. Phil. Tranſ. N°. 105.

The engine neceſſary for cutting the wood conſiſts of a long ſquare wooden block, and ſome pieces of iron to be faſtened on, and uſed about it, *viz.* a hammer, an anvil, an iron holding the wood to be bruiſed and cut, and a knife to cut it. The whole is a very ſimple and cheap machine, and is deſcribed at large, and figured in the above-mentioned number of the Philoſophical Tranſactions.

By Mr. de Buffon's experiments upon different ſkins, it was found that a decoction of young oak wood ſucceeded perfectly well in *tanning* ſheep and calves ſkins, but did not do equally well for ox, and the other harder ſkins. This, however, he imagines might be only for want of knowing the beſt method of uſing the wood. And certainly theſe trials deſerve to be farther proſecuted; ſince the ſmall branches of the oak, which are of little value, might be thus made to ſupply the place of a much dearer commodity, the bark; and as in many trees the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the uſe of theſe ſmall boughs, bark and all, might very probably be found to anſwer to all the effects of the bark, of the larger kind alone. Memoirs Acad. Scien. Par. 1736. See the Phil. Tranſ. above cited.

TANT,

TANT, in natural hiſtory, an Engliſh name for a ſmall ſpider of the opilio kind, having only two eyes, and eight very long legs, and commonly ſuppoſed to be very poiſonous.

It is all over of an elegant ſcarlet colour, reſembling that of the flowers of the red poppy when full blown, except that the belly has a whitiſh caſt. Four of its legs are inſerted in the upper part of the breaſt, and the other four near the belly; and near the origin of each leg there is a ſmall black ſpot. Its body is round and full, and it is all over covered with a fine ſhort velvety down. It is not unfrequent in dry paſtures in the ſpring ſeaſon. It is terribly dreaded by our farmers, who ſuppoſe that an ox will die who chances to ſwallow it. *Ray's* Hiſt. Inſect. p. 44.

TANTALUS, one of the many names given by the chemiſts to mercury.

TANZY, *Tanacetum*, in botany, *&c.* See the article TANACETUM.

TAOS *Lapis*, the *Peacock Stone*, a name given by ſome of the antient writers to a very beautifully variegated agate, reſembling, in ſome degree, the great variety of colours in the peacock's tail.

TAP *Root*, in trees, that part of the root that deſcends ſtrait down.

In removing or tranſplanting young oaks, great care ſhould be taken not to wound this root, much leſs to cut it off; but it muſt be dug up to the bottom, and the hole prepared deep enough to ſet it; otherwiſe the tree either dies, or if not, yet it is always greatly ſtinted and impeded in its growth. *Ray's* Engliſh Words, p. 129.

TAPAYAXIN, in zoology, the name of a very remarkable ſpecies of lizard, called by Hernandez the *lacertus orbicularis*. It is not of the long and ſlender ſhape of the common lizards, but as broad as it is long, and much reſembling the wray-fiſh in ſhape, though ſeldom exceeding four inches in length or breadth. It is a cartilaginous lizard, of a very beautiful variety of colours, always very cold to the touch, and ſo ſluggiſh a creature, that it often will not move out of its place even on touching it. Its head is extremely hard and elate, and has a ſort of crown of prickles for its defence; yet it is a perfectly harmleſs animal, and ſo far from having the fear of man, and ſhyneſs that other beaſts have, that it loves to be taken up and played with, and will ſtand perfectly ſtill, and ſeem very happy while handled. There is alſo another thing very ſingular in it, that if hurt about the head or eyes, or handled too roughly, it will throw out drops of blood from its eyes to three or four foot diſtance. *Ray's* Syn. Quad. p. 263. *Hernandez*, l. 9. c. 16.

TAPE-*Worm*, a ſpecies of worm breeding in the human bowels, and called by authors, *tænia*, and *lumbricus latus*, or the broad worm.

The Greek and Roman phyſicians, as well as thoſe of our own time, have deſcribed three ſorts of worms to which the human bowels are ſubject. The common long worms, which reſemble earth-worms; the aſcarides, or ſmall worms; and this *Tape worm*, which they have alſo called *vermis cucurbitinus*, or the gourd worm, from its ſeveral joints reſembling, in ſome degree, the ſeeds of that fruit.

The interpreters of ſome of the Greek phyſicians have however been guilty of a great error, in confounding the gourd worms and the aſcarides together, tho' nothing can be more unlike. The antients ſeem to have had a very juſt opinion of this animal, in calling it *vermis cucurbitinus*, ſince it is plain by this, that they underſtood every joint, as we call them, of this creature, to be a diſtinct worm; and what we call the ſingle worm, to be a long ſeries of theſe worms joined together end to end.

Petrus de Abano was one of the firſt whom we find deſcribing the ſeries of theſe creatures forming a chain of this kind, and repreſenting a ſingle and very long animal. Arnoldus de Villa Nova mentions two kinds of theſe worms; but he gives no farther deſcriptions of them than ſaying, that one kind is broad and long, the other broad and ſhort. After theſe, he mentions the long and round worm, which is the common kind; and fourthly, the ſmall worm, or aſcarides. To theſe he adds a fifth, which he calls ſolium, from its being found ſingle in the bowels. This he alſo calls *cingulum*; and obſerves, that it is very long and large, and that only one can live in the bowels at the ſame time.

It has been ſuppoſed by ſome, that what this author deſcribes as a ſeparate ſpecies of worm, under the name of *ſolium*, was no other than a kind of ſacculus or bag incloſing a long ſeries of theſe *Tape-worms*.

The writers that ſucceeded ran into great errors about theſe worms: Some declared them a mere figment of the Arabian phyſicians, affirming that no ſuch animals ever exiſted in nature. Others who believed in general that there was ſuch a ſpecies of worm, yet diſcountenanced all the ſtories related concerning it; and many who wrote on theſe ſubjects, mentioned two kinds of the lumbricus latus, or broad worm, but knew nothing of what was the difference between them.

Another ſet of writers, of whom Platerus is the head, diſtinguiſh, by certain characters, two ſpecies of broad worms; the one, they ſay, is long and broad, and not jointed; the other jointed, or formed like a chain; this is the common *Tape-worm*, which they ſuppoſe to conſiſt ſingly of a number of joints, contrary to the opinion of Petrus de Abano; and they ſay, that the vermis cucurbitinus of the Arabian writers, is only one of the joints, or a fragment of the jointed tænia, ſometimes voided in this manner in ſeparate pieces. Finally, others confounding the cucurbitini with the aſcarides, if ever they chanced to ſee a real *Tape-worm*, looked on it as ſome monſtrous production; nothing that had any name. *Clerici* Hiſt. Nat. Lumbr. Lat.

In later times this animal has been better known, and Tyſon, Lewenhoeck, Andry, and others, have treated very carefully of it, and all have referred it to the ſecond kind of tæniæ, mentioned by Platerus, which was of the ſhape of a chain, or compoſed of ſeveral joints, like ſo many links faſtened end by end to one another. Yet theſe have fallen into errors; and whent hey have found ſeveral of theſe tæniæ conjoined and encloſed in a ſacculus, they have taken the whole for one worm, whoſe head and tail they have deſcribed, but that in an inaccurate manner.

The true hiſtory of this animal is, that it is ſhort and broad. What is called a link of the long worm is really a diſtinct worm; and when one of theſe mutiplies in the bowels, its young adhere to it, and to each other endwiſe, ſo as to form a ſort of chain, which lengthens as they continue to increaſe, and in fine becomes immoderately long. Hence it is that the breaking, as it is called, of this worm, does not deſtroy it, and that the voiding large pieces of it is no cure, ſince it ſtill recovers that length again by new young ones. Every ſeparate link of ſuch a chain, if examined, is found to be entire, lively and briſk, and not at all injured by the ſeparation.

Authors who have treated of theſe worms as a diſeaſe, have given a canine appetite, or unnatural appetite to food, as one of the ſymptoms; but this is wrong, for it has never been found, in reality, that theſe worms, even where moſt numerous, have at all increaſed the natural appetite; and indeed it is very difficult to judge of their being in the body by ſymptoms, ſince they occaſion none which are not alſo common in many other diſeaſes. Many people have had them a long courſe of time, without being ſenſibly hurt by them; and there has never been a known inſtance of their occaſioning any one's death; or indeed any conſiderable diſorder. See the article WORMS.

TAPECON, in ichthyology, a name given by ſome to the fiſh generally called the *uranoſcopus*, or ſtar-gazer. It is properly a ſpecies of the trachinus, and is diſtinguiſhed by Artedi by the name of the *trachinus* with ſeveral beards at the lower jaw. *Aldrovand.* de Piſc. p. 258.

TAPERA, in zoology, the name of a Braſilian ſwallow, called by the Portugueſe there, *andorintra*. It is of the ſize and ſhape of our ſwallow, and it flies about in the ſame manner. The head, back, neck, wings and tail, are all of a greyiſh brown; and its throat and breaſt of a greyiſh white. *Marggrave's* Hiſt. Braſ.

TAPETI, in zoology, the name of an animal common in the Weſt Indies, and called by ſome, *cuniculus Americanus*, the American rabbit.

It is exactly of the ſhape of our common rabbit, and is of about double the ſize of the dormouſe. Its hair in length and colour is like that of the hare, and its ears long and erect, in the manner of our rabbits. It has a little reddiſhneſs on the forehead, and is ſomewhat whitiſh under the throat. It has uſually alſo a ſort of white circle or collar round the neck; but ſome of this ſpecies want that, and have their whiteneſs only under the throat, breaſt, and belly. It has no tail; its eyes are black, and its mouth bearded in the manner of our rabbits. The Indians eat the fleſh of it. *Ray's* Syn. Quad. p. 205.

TAPHICESIUS *Lapis*, a name given by Pliny and the antients to a ſpecies of ætites, or eagle-ſtone, found in a place of that name near Leucadia.

TAPHNEUS, a word uſed by ſome writers to expreſs any thing when depurated or purified to the greateſt degree, as the ſalts by repeated ſolutions and cryſtallizations, and the like. Paracelſus uſes it for a ſpecies of earth, the things produced from which, he ſays, never alter their nature by calcination or reverberation, or the like operations.

TAPIA, in botany, a name given by Plumier to a genus of plants called afterwards by Linnæus, *crateva*. *Plum.* Gen. 21. See the article CRATEVA.

TAPIJERETE, in natural hiſtory, the name of an animal found in ſome parts of America, and called by the Portugueſe, *anta*. It is of the ſize of a young calf, and in ſhape ſomewhat approaching to the figure of the hog. Its head is thicker than a hog's, and ends in a ſharp ridge at top; and has a ſnout hanging over the opening of the mouth, in which he has a very ſtrong muſcle, ſerving to retract it at pleaſure. The dentes inciſores are ten in each jaw; from the end of theſe the jaw ſeems toothleſs for a little ſpace. The grinders are large, and are placed five on each ſide; ſo that, on the whole, the creature has twenty of each ſort of teeth. Its eyes are ſmall, and very like thoſe of the hog; its ears roundiſh; and theſe he can draw forward at pleaſure. Its legs are thick, and not longer than thoſe of our hogs. Its hoofs are divided into four portions. It has no tail; the ſkin is hard and ſolid; and the hair ſhort, and of a pale brown, variegated with white ſpots. It lives in the thick woods, and ſleeps all day; but at night, or early in the morning, goes out for its prey. It feeds on

vegetables, and is particularly fond of the stalks of the sugar-cane; it often takes the water, and swims excellently. The natives, in places where it is common, eat its flesh; which is but very coarse and ill tasted. *Ray's* Syn. Quad. p. 140.

TAPINOSIS, Ταπείνωσις, in rhetoric, the same with *diminution*. See the article DIMINUTION, *Cycl.*

TAPLINGS, in the English salt-works, the name given to certain bars of iron which support the bottom of the pan in which the brine is boiled.

These pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would spoil the working the salt, there is a sort of wall of brick carried along the middle of the furnace; and on the top of this are placed these *Taplings*: They are about eight inches high, and from four to six in thickness, being smallest at the top. These are placed at about three foot distance one from another, and the wall which supports them, and which is called the *midfeather*, is broad at the base, and so narrow at the top, as barely to give room for the bases of the *Taplings*.

TAPPING (*Cycl.*)—In *tapping* for the dropsy, surgeons were formerly very careful to draw off only a small quantity of water at one time, and therefore repeated it often, till the whole was evacuated. The reason of this was to avoid the syncope, which usually attended the operation when all the water was evacuated at once. But Dr. Mead having discovered the true cause of this syncope to be owing to the removal of the pressure from the descending aorta, it was soon found, that the bad consequences might be prevented by emptying the belly at one operation, and preserving a proper pressure at the same time, which should be done equally and gradually, as the water runs out. Bandages have been contrived for this purpose in England and in France; but, according to Mr. Monro, they are not sufficient; and he therefore invented a belt made of fine flannel, and strong linnen, which will better answer the purpose. For the draught and description of this belt, we refer to the Medic. Ess. Edinb. vol. 1. art. 18. or its abridgment, vol. 2. p. 102. where the curious may find several practical observations about this operation.

Tapping has seldom proved more than a palliative remedy in dropsies. The chief improvements in the operation are owing to Mr. Monro, Monsieur Garengeot, and Mr. Warwick.

Mr. Monro has substituted a belt instead of the ordinary long bandage for compressing the abdomen; and has also ascertained the proper place of puncture. Garengeot makes the evacuation at once, cleans the emptied cavity, to remove the feculent part of the waters which subsides therein, and is apt, by its acrimony, to occasion mortifications.

Mr. Warwick tells us, however, that notwithstanding these improvements, an ascites shews, that the use of *Tapping* is but precarious, by returning as constantly as ever this method alone is put in practice to remove it. He has therefore endeavoured at a farther improvement, whereby the *Tapping*, instead of being a bare temporary relief of symptoms, becomes an absolute cure. This method is, after evacuating the waters, to make an injection of equal parts of cahors, wine, or claret, and Bristol water, blood-warm, into the emptied cavity. He mentions a cure he performed in this manner. See Phil. Transf. N°. 472. Sect. 3.

Dr. Hales has given us, in the same transaction, sect. 4. a method of conveying liquors into the abdomen during the operation of *tapping*, by means of two trocars fixed at the same time one on each side of the belly, one of them having a communication with a vessel full of the medicinal liquor, by means of a small leather pipe. This vessel might be raised high enough above the abdomen to force the liquor in by the laws of hydrostatics. The advantage proposed by this method, is to prevent a syncope from inanition. See a farther account of the success of injecting medicated liquors into the abdomen, in the case of an ascites, in Phil. Transf. N°. 473. Sect. 4.

TAR (*Cycl.*)—The antients esteemed *Tar* good against poisons, ulcers, the bites of venomous creatures; also for pthisical, scrophulous, paralytic and asthmatic persons. But the method of rendering it an inoffensive medicine, and agreeable to the stomach, by extracting its virtues in cold water, was unknown to them. Siris, Sect. 9. See the article TAR-*Water*, infra.

According to Pliny, liquid pitch, as he calls it, or *Tar*, was obtained by setting fire to billets of old fat pines or firs. The first running was *Tar*, the latter, or thicker running, was pitch. Theophrastus is more particular; he tells us, that the Macedonians made huge heaps of the cloven trunks of those trees, wherein the billets were placed erect beside each other. That such heaps or piles of wood were sometimes an hundred and eighty cubits round, and sixty, or even an hundred high; and that, having covered them with sods of earth, to prevent the flame from bursting forth (in which case the *Tar* was lost) they set on fire those huge heaps of pine or fir, letting the *Tar* and pitch run out in a channel made for that purpose. Siris, Sect. 13.

Some modern writers inform us, that *Tar* flows from the trunks of pines and firs, when they are very old, through incisions made in the bark near the root; that pitch is only *Tar* inspissated, and both are the oil of the tree grown thick and black with age and the sun. The trees, like old men, being unable to perspire, and their secretory ducts obstructed, they are, as one may say, choaked and stuffed with their own juice [a]. But the method used by our colonies in America for making *Tar* and pitch, is, in effect, the same with that of the antient Macedonians; as appears from the account given in the Philosophical Transactions. And the relation of Leo Africanus, who describes, as an eye-witness, the making of *Tar* on mount Atlas, agrees in substance with the methods used by the Macedonians of old, and the people of New England of this day [b].—[[a] Siris, Sect. 16. [b] Id. Sect. 17.]

According to Theophrastus, not only the turpentine-trees, the pines, and the firs, yield resin or *Tar*, but also the cedars and palm-trees; and the words *pix* and *resin* are taken by Pliny in so large a sense, as to include the weepings of the lentiscus and cypress, and the balms of Arabia and Judæa; all which perhaps are near of kin, and in their most useful qualities concur with common tar, especially the Norwegian, which is the most liquid and best for medicinal uses. Those trees that grow on mountains, exposed to the sun or north wind, are reckoned to produce the best and purest *Tar*; and the Idæan pines were distinguished from those growing on the plane, as yielding a thinner, sweeter, and better scented *Tar*. Id. Sect. 28.

Tar in substance, mixed with honey, has been found an excellent medicine for coughs. Id. Sect. 21.

TAR-*Water*. As the cold infusion of *Tar* has been lately much in vogue, and has been recommended by one of the most learned and ingenious writers of the age, it may not be improper to give some account of its virtues from the bishop of Cloyne's *Siris*, or Chain of Reflections concerning the Virtues of *Tar-water*.

In some parts of America, *Tar-water* is made by putting a quart of cold water to a quart of *Tar*, and stirring them well together in a vessel, which is left standing till the *Tar* sinks to the bottom. A glass of clear water being poured off for a draught, is replaced by the same quantity of fresh water, the vessel being shaken, and left to stand as before. And this is repeated for every glass, so long as the *Tar* continues to impregnate the water sufficiently, which will appear by the smell and taste.

But as this method produces *Tar-water* of different degrees of strength, the author says, he chuses to make it in the following manner: Pour a gallon of cold water on a quart of *Tar*, and stir and mix them thoroughly with a ladle or flat stick, for the space of three or four minutes; after which the vessel must stand eight and forty hours, that the *Tar* may have time to subside; when the clear water is to be poured off, and kept for use, no more being made from the same *Tar*, which may still serve for common purposes.

This cold infusion of *Tar* hath been used in some of our colonies as a preservative or preparative against the small pox, which foreign practice induced the bishop to try it in his own neighbourhood, when the small pox raged with great violence. He says, the trial fully answered his expectation; all those within his knowledge, who took the *Tar-water*, having either escaped that distemper, or had it very favourably. Several were preserved from taking the small-pox, by the use of this liquor; others had it in the mildest manner; and others, that they might be able to take the infection, were obliged to intermit drinking *Tar-water*. He says, he has found it may be drank with great safety and success for any length of time, and this not only before, but also during the aforesaid distemper.

The general rule for taking it, is about half a pint night and morning, on an empty stomach, which quantity may be varied according to the case and age of the patient, provided it be always taken on an empty stomach, and about two hours before or after a meal.

It has been found, that several persons infected with cutaneous eruptions and ulcers, were immediately relieved, and soon after cured, by the use of this medicine. It is said, that even in the foulest distempers, it proved much more successful than salivations and wood-drinks had done. It also succeeded beyond expectation, in a tedious and painful ulceration of the bowels, in a consumptive cough, and (as appeared by expectorated pus) an ulcer in the lungs, in a pleurisy and peripneumony. And when a person who had been for some years subject to erysipelatous fevers, perceived the usual forerunning symptoms to come on, the drinking of *Tar-water* prevented the erysipelas.

Tar-water cures indigestion, and gives a good appetite. It is an excellent medicine in an asthma; it imparts a kindly warmth, and quick circulation to the juices, without heating, and is therefore useful, not only as a pectoral and balsamic, but also as a powerful and safe deobstruent in cachectic and hysteric cases. As it is both healing and diuretic, it is very good for the gravel. The bishop says, he believes it to be of great use in a dropsy, having known it cure a very bad anasarca in a person whose thirst, though very extraordinary, was in a short time removed by the drinking of *Tar-water*. It may likewise be safely used in inflammatory cases; and, in fact, hath been found an admirable febrifuge, at once the safest cooler and cordial.

The salts, and more active spirits of *Tar* are got by infusion in cold water; but the resinous part is not to be dissolved thereby.

thereby. Hence the prejudice which ſome, perhaps, may entertain againſt *Tar-water*, the uſe whereof might inflame the blood, by its ſulphur and reſin,as a medicine, appears to be not well grounded. It is obſerved by chemiſts, that all ſorts of balſamic wood afford an acid ſpirit, which is the volatile oily ſalt of the vegetable. Herein is chiefly contained their medicinal virtues; and this author affirms, that by the trials he has made, it appears, that the acid ſpirit in *Tar-water* poſſeſſes the virtues, in an eminent degree, of that of guaiacum, and other medicinal woods.

It is certain *Tar-water* warms, and therefore ſome may perhaps ſtill think it cannot cool. The more effectually to remove this prejudice, let it be farther conſidered, that, as on one hand, oppoſite cauſes do ſometimes produce the ſame effect; for inſtance, heat by rarefaction, and cold by condenſation, do both increaſe the air's elaſticity; ſo, on the other hand, the ſame cauſe ſhall ſometimes produce oppoſite effects. Heat, for inſtance, in one degree thins, in another coagulates the blood. It is not therefore ſtrange, that *Tar-water* ſhould warm one habit, and cool another; have one good effect on a cold conſtitution, and another good effect on an inflamed one; nor, if this be ſo, that it ſhould cure oppoſite diſorders. All which juſtifies to reaſon, what has often been found true in fact. The ſalts, the ſpirits, the heat of *Tar-water*, are of a temperature congenial to the conſtitution of a man, which receives from it a kindly warmth, but no inflaming heat. It is of admirable uſe in fevers, being at the ſame time the ſureſt, ſafeſt, and moſt effectual both paregoric and cordial; for the truth of which the biſhop appeals to any man's experience, who ſhall take a large draught of it milk warm, in the paroxiſm of a fever, even when plain water and herb teas ſhall be found to have little or no effect. To him it ſeems, that its ſingular and ſurprizing uſe in fevers of all kinds, were there nothing elſe, would be alone ſufficient to recommend it to the public. As *Tar-water* poſſeſſes the virtues of fortifying the ſtomach, as well as purifying and invigorating the blood, it may be preſumed of great and general efficacy in all thoſe numerous illneſſes, which take their riſe from foul or vapid blood, or from a bad digeſtion. The animal ſpirits are elaborated from the blood; ſuch therefore as the blood is, ſuch will be the animal ſpirits, more or leſs, weaker or ſtronger. This ſhews the uſefulneſs of *Tar-water* in all hyſteric and hypochondriac caſes; which, together with the maladies from indigeſtion, comprize almoſt the whole tribe of chronical diſeaſes. In very dangerous and acute caſes, much may be taken, and often, as far as the ſtomach can bear. But in chronical caſes, about half a pint, night and morning, may ſuffice. A medicine of ſo great virtue in ſo many different diſorders, and eſpecially in that grand enemy the fever, muſt needs be a benefit to mankind in general. There are nevertheleſs three ſorts of people to whom the biſhop ſays he would peculiarly recommend it; ſea faring perſons, ladies, and men of ſtudious and ſedentary lives.

To ſailors, and all ſea-faring perſons, who are ſubject to ſcorbutic diſorders, and putrid fevers, eſpecially in long ſouthern voyages, he is perſuaded this *Tar-water* would be very beneficial. And this may deſerve particular notice, when ſo many of our countrymen have periſhed by ſuch diſtempers, contracted at ſea, and in foreign climates, which, it is probable, might have been prevented by the copious uſe of *Tar-water*.

This ſame water will alſo give charitable relief to the ladies, who often want it more than the pariſh poor; being many of them never able to make a good meal, and ſitting pale, puny, and forbidden like ghoſts, at their own table, victims of vapours and indigeſtion. Studious perſons alſo pent up in narrow holes, breathing bad air, and ſtooping over their books, are much to be pitied; as they are debarred the free uſe of air and exercife; this, he ſays, he will venture to recommend as the beſt ſuccedaneum to both. Though it were to be wiſhed, that modern ſcholars would, like the antients, meditate and converſe more in walks and gardens, and open air; which, upon the whole, would perhaps be no hindrance to their ſtudies.

It has been inſinuated, that *Tar-water*, made in the common way, as here deſcribed, contains noxious oils or particles of *Tar*, which renders it dangerous to thoſe who drink it. But the biſhop ſays, this is contrary to all his experience, and that *Tar-water* is ſo far from doing hurt by any cauſtic or fiery quality, that it is, on the contrary, a moſt potent medicine for the allaying of heat, and curing of all inflammatory diſtempers.

It has alſo been publickly aſſerted, that the acid juice of *Tar*, freed from the volatile oil, is much more ſafe and efficacious than *Tar-water*. But the above-mentioned author is of opinion, that if *Tar-water* be robbed of its fine volatile oil (which neither ſinks to the bottom, nor floats at the top, but is intimately united with it, and appears to the eye only in the colour of *Tar-water*) it can be no cordial, he having obſerved, that the moſt acid water is the leaſt cordial; ſo far is he from imputing the whole virtue to the acid, as ſome have thought. See *Two Letters from the Biſhop of Cloyne*, &c. publiſhed 1747.

The ſame author obſerves, that the uſe of *Tar-water*, made a ſecond time from the ſame *Tar*, is not at all noxious, or of a fiery cauſtic nature, only it is not ſo ſtrong as that firſt made. If it be aſked, what preciſe quantity or degree of ſtrength is requir'd in *Tar-water*? it is anſwered, that the palate, the ſtomach, the particular caſe and conſtitution of the patient, the very ſeaſon of the year will diſpoſe and require him to drink more or leſs in quantity, ſtronger or weaker in degree. Preciſely to meaſure its ſtrength by a ſcrupulous exactneſs, is by no means neceſſary.

It is to be obſerved, that *Tar-water* ſhould not be made in unglazed earthen veſſels, theſe being apt to communicate a nauſeous ſweetneſs to the water.

The ſame ingenious author recommends *Tar-water* in the plague, and for the diſtemper among the horned cattle now raging; with what ſucceſs muſt be left to experience.

TARABE, in zoology, the name of a Braſilian parrot, larger than the common green parrot. Its general colour is green; but its head, breaſt, and the origin of its wings, are red. Its beak and legs are of a duſky grey. *Marggrave's* Hiſt. Braſ.

TARAE *Lapis*, the name given by the writers of the middle ages to a ſtone which they ſay had the power of ſtopping all ſorts of fluxes. They have left us no deſcription of it, and it ſeems to have been loſt even in their times; for they obſerve that the phyſicians uſed the ſanguis draconis, or dragon's-blood, in its place.

TARAGUICO *Aycuraba*, in zoology, the Braſilian name for a ſpecies of lizard, much approaching to the nature of the taraguira; but its tail is covered from its beginning with ſmall triangular ſcales, and very regularly marked with four brown ſpots. The back alſo, particularly that part which is next the head, is variegated with undulated brown lines. *Ray's* Syn. Quad.. p. 266.

TARAGUIRA, in zoology, the name of an American lizard. It grows to about a foot long; its body is rounded, and every where covered with ſmall triangular duſky grey ſcales. Its back is ſmooth, and it has not that falſe gullet under the throat which the iguana has.

This is the ſpecies of lizard of which it is reported, that it will wake a ſleeping perſon, if it ſee him in danger of being bitten by a ſerpent. It is very common about houſes and gardens in South America, and runs very ſwiftly, but with a waddling motion; and when it ſees any thing at a diſtance, has an odd way of nodding its head very ſwiftly. *Ray's* Syn. Quad. p. 266.

TARANDUS, in zoology, a name given by Agricola, and ſome other authors, to the rein deer. See the article RANGIFER.

TARANIOLO, in zoology, a name by which the whimbrel, or ſmall curlew, called the *arquata minor* by authors, is known in the markets of Italy. *Ray's* Ornithology. p. 217.

TARANTULA, (*Cycl.*) in zoology, a name given by the Italians to a peculiar ſpecies of lizard, called by Aldrovand and ſome others, *lacertus facetanus*. See Tab. of Quadrupeds and Serpents, N°. 36.

It is of a grey colour; its ſkin is extremely rough; and it is thicker and rounder bodied than the other lizards. It is found like our common eft, under old walls, and among the ruins of buildings, particularly in the neighbourhood of Rome, in great plenty; its colour looks dead and ghaſtly, and it is as odious to the ſight among the Italians, as the toad is with us, being never ſeen without a ſort of natural horror. It is eſteemed alſo a poiſonous creature, as the toad is with us, tho' it is not eaſy to find well-atteſted ſtories of any bodies ever having been hurt either by the one or the other of theſe creatures. *Ray's* Syn. Quad. p. 264.

TARBASON, a word uſed by ſome chemical writers as a name for antimony.

TARCONANTHUS, in botany, the name of a plant deſcribed by Vaillant, the characters of which are the ſame with thoſe of the parthenium. *Vaillant*, A. G. 1719. See the article PARTHENIUM.

TARDA *Avis*, in zoology, a name given by many to the buſtard, more commonly known among authors by the name *otis*. *Ray's* Ornithology, p. 129. See the article OTIS.

TARDO, in the Italian muſic, is uſed to denote a ſlow movement, being much the ſame as *largo*. See the article LARGO.

TAREIBOIA, in zoology, the name of a ſpecies of ſerpent found in America, and called alſo *cacaboia*; though, according to ſome authors, the *Tareiboia* and *cacaboia* are two different ſpecies.

They are both of the amphibious kind, and live in lakes and waters, as well as on land; but they are not very poiſonous. They are ſmall ſnakes, and all over black; when offended, they will bite; but the wound is eaſily curable. Authors have written differently of theſe ſerpents, ſome making the latter very different from the former, and of a yellow colour. *Ray's* Syn. Anim. p. 329.

TAREIRA, in ichthyology, the name of a fiſh caught in the American ſeas, and eaten; but of no fine flavour.

It is of an oblong and thick body, gradually tapering toward the tail. Its head reſembles that of a ſnake, and is raiſed into two tubercles over the eyes: Its eyes are yellow, with a black pupil; its noſe pointed, and its mouth large and yellow within. It has extremely ſharp teeth in both its jaws, and on its tongue. It has eight fins, the tail being accounted one, and this is forked; but this, as well as the reſt, is of the conſiſtence of a poppy leaf, tender, thin, and ſoft, and ſuſtained by ſoft rays. Its ſcales are ſo nicely laid on one another, that it ſeems ſmooth to the touch. Its belly is white, and its back and ſides are variegated with longitudinal green and yellow lines. *Marggrave's* Hiſt. Braſ.

TARGAR, a name given by fome of the chemical writers to oil of juniper.

TARIERA, in ichthyology, the name of a river-fifh caught in many parts of America.

It is an oblong fifh, with a ftrait back, and a belly fomewhat hanging down. Its under jaw is longer than its upper, and its teeth are extremely fharp. Among thefe there are two longer than the reft in the middle of the under jaw, and four fuch in the upper. Its fcales are large, and its back brown, and its belly and fides whitifh. It is a well tafted fifh, but full of bones. *Marggrave's* Hift. Braf.

TARIFILON, in botany, a name by which Avicenna, and fome other authors, have called the *trifolium bituminofum*, or ftinking trefoil. *Ger. Emac.* Ind. 2.

TARIN, in ornithology, a name given by the French, and from them by many others to the *Citrinella*; a bird common in Italy, and kept in cages for its beauty and fine notes. *Ray's* Ornithol. p. 93. See the article CITRINELLA.

TARINGTING, in natural hiftory, a name given by the people of the Philippine iflands to a fpecies of lapwing which is common on the fea-fhores, and runs remarkably fwift.

TARITH, one of the many names given by the chemifts to mercury. See the article MERCURY.

TARRAGON, in botany. See the article DRACUNCULUS.

TARROCK, in zoology, the name of a fea-fowl of the larus or gull-kind, and diftinguifhed by authors by the name of the *larus cinereus Bellonii*.

It is of the fize of the common pigeon, and is not much unlike it in fhape, except that the head is larger and thicker. Its tail is not forked; and its throat, breaft and belly, are fnow-white. Its head and the outer part of its neck are alfo white; but there is on each fide of the head a black fpot. The lower part of the neck is black; and the middle of the back and the fhoulders are grey. Its long wing feathers are black and white. Its great diftinction, however, from all the other birds of the gull kind, is, that it has no hinder toe. It is very common on the coafts of Cornwal, and fome other of the Englifh fhores. *Ray's* Ornithol. p. 264.

TARSI, in the materia medica, a name by which fome authors have called the root of the *cyperus efculentus*, or fweet cyperus of the fhops; and by which it is in fome places ufually called by the druggifts. *Dale's* Pharm. p. 257.

TARSO, in the glafs-trade, a fort of white ftone found in many rivers of Italy, and other places; and ufed inftead of fand for the fineft cryftal glafs, being firft burnt, and calcined with the falt of the polverine into frit. *Neri's* Art of Glafs, p. 7.

Neri calls this ftone a kind of white marble; and adds a general rule, that all ftones that will ftrike fire with fteel, are fit to vitrify; and thofe that will not ftrike fire with fteel, will never vitrify.

The criteria or determinate characters of foffils were not at all fixed in this author's time, otherwife he had not called this ftone a kind of marble; fince his own general rule of trying ftones by fteel, is, though liable to a few exceptions, a very good one; and, according to that, this *Tarfo* could be of no affinity to marble; for marble will not ftrike fire with fteel, nor ever be converted into glafs.

The great difference of ftones is this; fome are compofed of cryftal, varioufly debafed by adventitious matter; others of fpar, debafed in the fame manner. All cryftal will give fire with fteel; all fpar will refufe this. Flints, fand, and the harder ftones, are compofed of cryftal; and will therefore give fire with fteel, and vitrify or make glafs with the addition of falts. Marble, and other foft ftones, are compofed of fpar; and can neither give fire with fteel, nor make glafs, but readily calcine in the fire.

The *Tarfo* therefore, of this and other authors, could be nothing of the marble kind; but is truly a cryftalline matter debafed by an admixture of white earth, and found in form of fmall pebbles of a whitifh, yellowifh, or pale reddifh colour; and this is common in all the gravel-pits of England, and in the beds of fome of our rivers; and might be ufed with great advantage by our glafs-makers, if they knew it was fo eafily to be had.

On comparing thefe ftones of ours, with the cuogolo or *Tarfo* of the foreign glafs-makers, there is no difference diftinguifhable to the eye, nor will the niceft experiments by the fire, acid menftrua, *&c.* fhew the leaft diftinction between them. We are not to wonder however, that the glafs-makers did not hitherto diftinguifh this to be the true cuogolo or *Tarfo*, fince the characters of foffils have been hitherto fo little afcertained, that the beft and lateft author on thefe fubjects, Dr. Woodward, fo far miftook the ftructure of this ftone, as to call it a fparry pebble. It is certain that fpar could never have any thing to do with glafs-making; but this ftone has no fpar in its compofition.

TARSUS (*Cycl.*)—*Bones of the* TARSUS *luxated*. If any of the fmall bones in the foot, the *tarfus* or *metatarfus* happen to be luxated by fome external violence, the ligaments with the adjacent nerves and tendons, are generally fo affected as to excite not only the moft acute pains, but alfo violent inflammations and convulfions, and even death itfelf has been known to be the confequence of accidents of this kind, unlefs the bones be fpeedily replaced. The foot is for this purpofe to be extended on an even table, and the furgeon is to replace the diflocated bones with the preffure of the palms of his hands, adjufting them alfo with his fingers, where need requires. Compreffes dipped in warm fpirit of wine are then to be laid on the part, and both thefe and the reduced bones fecured in their places, by means of the proper bandages; the patient is then to be enjoined to remain in bed till the new fet bones have acquired a fufficient ftrength. *Heifter's* Surg. pag. 174.

TARTAR (*Cycl.*)—The fweet wines afford always lefs *Tartar* than the fharp ones, and it is alfo lefs valuable. The *Tartar* of Rhenifh wine, is better than that of any other; and in general, thofe wines which have the moft acid in them, afford the greateft quantity of *Tartar*, and that in the largeft cryftals. It is objected by fome to this fyftem, that vinegar affords no *Tartar*; but this is eafily anfwered, by obferving, that the wine from which vinegar is made, has before depofited its *Tartar*. This falt of wine may be by chemiftry reduced to elementary water, in this manner: let it be burnt to a fixed falt, and let this fixed falt of *Tartar* be diffolved by ftanding in a damp place into an oil *per deliquium*; let this oil be diftilled in an alembic, and a phlegm only comes over: by repeating this procefs, the whole will be reduced into perfect fimple and infipid phlegm, excepting a fmall remainder of equally infipid earth. *Portzius* de Vin. Rhen.

Befide the ufual way in which *Tartar* is produced, there is a very remarkable account in the Memoirs of the Academy of Sciences at Paris, of its having been found in a more than ordinary beautiful ftate on a human fkull; the difcovery was owing to accident, and was in this manner:

Mr. Morand wanting a human fkull cleanfed from its foft parts, put into a dunghill of horfe-dung a whole human head; after it had lain there eight days, the flefhy parts eafily feparated, being as it were boiled to pieces; after this the fkull was carefully wafhed, and then laid to foak for ten days in a large veffel of water; after this it was drenched three or four times in frefh water, and finally, without wiping, was fet out in the air to dry. As it dried it became covered with little cryftals, compofed of feveral planes or traces, but moftly of a cubic form, very bright and glittering; and when expofed to the light, of an extremely brilliant water. There were none of them on the bafis of the cranium, which was full of irregularities; but they all arranged themfelves on the upper part above the orbitary hollows; to the jaw-bones there were alfo many faftened, as alfo to the teeth; thefe laft were yellow, but they were not lefs bright and brilliant than the reft.

On examining thefe cryftals they were found to be *Tartar*, but in a purer ftate than *Tartar* is ever ufed to appear in; and as it was foon judged that though thefe cryftals owed their prefent form and extreme beauty to the fkull, yet they could not be wholly produced from it, the whole matter was carefully examined, and it was found that there had been lees of wine in the veffel in which the fkull had been laid ten days in foak. Mem. Acad. Par. Ann. 1737.

The formation of the cryftals of this *Tartar* on the fkull, while the fides of the veffel had none concreted on them, fhews that the fkull had a difpofition for receiving the cryftals more than any other body; and their peculiar brightnefs proves, that it had fome fhare in their formation.

The ufual method of refining *Tartar* is this: Take two pounds of common white *Tartar* reduced to powder, and put it into five gallons of fair water; put it over the fire to boil, and in the mean time beat up the whites of two or three eggs, mix thefe among the liquor, and fkim it as it heats; finally ftrain it and fet it in a cool place for two days, at the end of which time a quantity of whitifh cryftals will be found fticking to the fides of the veffel.

This is a very troublefome and inconvenient procefs, the *Tartar* requiring fo very large a quantity of water to diffolve it; and the operation muft alfo be repeated more than once, to make the cryftals fine. Veffels of metal cannot be employed, becaufe the *Tartar* would corrode them; and earthen ones of fize to make large quantities, are not eafily procured. In many arts the crude *Tartar* does as well as the refined; but in many other occafions none but the refined can be ufed. It were therefore much to be wifhed, that we could get into a method of refining it here, as they do in France. *Shaw's* Lectures, p. 158.

A great affiftance in the diffolving of *Tartar* is had from adding lime-water, pot-afhes, or falt of *Tartar*; and if the alkali be here too great, it may be taken off by a proper quantity of oil of vitriol. But where a very pure *Tartar* is required, the beft method of obtaining it is to diffolve the common cryftals or cream of *Tartar* in water, made highly acid with oil of vitriol. For this folution, after a proper evaporation, will afford perfectly fine cryftals of *Tartar*, no way participating of the oil of vitriol.

The glafs-men are very fond of a preparation, which they call burnt *Tartar*. This is no more than the larger lumps of red *Tartar*, burnt or calcined in earthen pans in an open fire till they have done fmoaking, and is of a blackifh purple colour. *Neri's* Art of Glafs, p. 69.

Soluble

Soluble TARTAR. The process for making *soluble Tartar*, is this: Take of an alkaline fixed salt a pound, of water a gallon; and having dissolved the salt in this water boiling, throw in crystals of *Tartar* in powder as long as any fermentation is raised, which usually ceases before thrice the weight of the alkali is thrown in. Then strain the liquor through paper; and after due evaporation set it by for the salt to crystallize, or else evaporate the liquor wholly away, that the salt may be left dry.

This salt by the action of the alkali on the acid of *Tartar*, being freed from those gross terrestrious parts, with which the crystals of *Tartar*, how pure soever, remain still charged; it dissolves readily, and keeps suspended in cold water. *Pemberton's* London Dispensatory, p. 181. seq.

The several alkaline salts, that of *Tartar* itself, the common pot-ashes, borax, &c. all make a very good *soluble Tartar*; and not only these but the common terrestrial alkali's, whether of the mineral kingdom as chalk or lime, or of the vegetable, as the ashes of plants after elixiviation; or of the animal, as oyster-shells calcined or not calcined, and hartshorn; all these give a better or worse *soluble Tartar*; but of these none succeeds so well as the oyster-shell, after it has been calcined; the *soluble Tartar* prepared with this, costs also greatly less, than when prepared with salt of *Tartar*.

In wood-ashes there is always a part, which when mixed with water swims, and is suspended in it a long time, and at length subsides into a kind of soft and impalpable matter; and another part, which subsides readily to the bottom, and feels rough and harsh. It is the first of these substances alone, which being mixed with cream of *Tartar*, renders it soluble: The other part will not mix with the cream of *Tartar*, or produce any such effect, unless reduced to the nature of the first, by repeated and violent calcinations, and then only a part becomes so altered, the whole never is so. It appears that the first portion has been wholly divested of its acid by the fire, and thence is become susceptible of the impression of the weakest acid, such as is that of the cream of *Tartar*; but in the second, or coarser part, the acid it naturally contained remains fixed and concentrated, so that it is not susceptible of any impression from the weak acid of the cream of *Tartar*. Mem. Acad. Par. 1733.

The different kinds of *soluble Tartar* have also their different degrees of solubility, or different readiness to run into a liquor *per deliquium*. The most easily soluble of all others are those made with chalk, with lime, and with wood-ashes; and that which is most differently so, is the kind made with borax; it will at length run however, and is truly *soluble Tartar*.

Regenerated TARTAR. When cream of *Tartar* has been made soluble by any alkaline substance whatever, it may be revived or regenerated into cream of *Tartar* again; its acid in this state has dissolved the alkaline matter presented to it, and that has been itself attenuated in such a manner as to render it capable of insinuating itself between the molecules or integrant parts of the constituent matter of the cream of *Tartar*; on this only depends the solubility of this preparation: and to render the whole of its primitive nature again, there requires no more than the addition of a new acid, which shall free the *Tartar* from this alkali; but this must necessarily be stronger than that naturally in the *Tartar*. Thus spirit of nitre, or oil of vitriol, regenerate the *soluble Tartar* in a moment, as being more powerful acids than that in the cream of *Tartar* and therefore taking from it all its alkali's.

It might be supposed also, that these being mineral acids, and that of the *Tartar* a vegetable one, they might therefore be the more proper to take up its alkali's; but this is found not to be the case, for the acid of distilled vinegar, which is not only a vegetable acid, but is also the very same acid with that of *Tartar*, is also able to regenerate the soluble *Tartars*. It might seem wonderful that this should be able to effect this change without any superiority of force; but it is to be observed, that in the cream of *Tartar* the acid has a terrestrial and alkaline basis, which is natural to it in that form; but in the state of *soluble Tartar* it takes a new alkaline basis, which is not natural to it, but is such as the artist gives it; and when we view the process in this light, it does not appear wonderful that an acid of its own kind should be able to take away from it this artificial alkaline basis, though it was not able to take from it the natural one. Mem. Acad. Par. 1733.

This second or artificial basis is different, according to the different alkali's which have been employed to render the *Tartar* soluble, and consequently the same acid may attach itself more to one than to another of those alkali's, and quit them the more or less easily. There is one kind of *soluble Tartar* however, which is not to be regenerated at all; this is that, which is made with borax.

Dr. Huxham says, he as often experienced the good effects of *regenerated Tartar* in the cure of obstructions of the bowels, and for sluggish humours. See the article OBSTRUCTIONS *of the Bowels*.

TARTARI *Lixivium*. See the article LIXIVIUM *Tartari*.

TARTARON, a sort of fine cloth or silk, mentioned in the stat. 4 Hen. VIII. c. 6. *Blount*, *Cowel*.

TARTARUM *Tartarisatum*, *Tartaris'd Tartar*, in chemistry, the name of a preparation of *Tartar*; the manner of doing which is given by Boerhaave, and is as follows: Reduce some of the purest white *Tartar* to powder, and boil this powder in ten times its weight of water in a large copper vessel, till it appears perfectly dissolved; let it after this continue boiling till the liquor become tolerably transparent, and of an acid taste; then drop into it from on high oil of *Tartar per deliquium*, the liquor being still kept boiling; upon the falling in of each drop there arises a great ebullition, occasioned by the meeting of the acid and alkali. Large bubbles appear on this, and in these the chemists have imagined they found the figures of clusters of grapes.

The operation is to be patiently continued till there is no more effervescence made by the falling in of the drops of the oil. The acidity of the *Tartar* will be then so perfectly saturated with its own alkali, that it will appear neither acid nor alkaline, but a third salt; great caution however must be used in observing the true point of saturation, otherwise the salt will be when finished either a little acid, or a little alkaline, as the one or the other exceeds.

The liquor is then to be strained several times through a flannel, till perfectly clear; it is of a deep brownish colour, and brackish saline taste, but has no scent. If this be evaporated to a pellicle, and set to crystallize, it forms a salt which is a *Tartar*, easily soluble in water, even when cold; and is very properly to be called soluble *Tartar*. *Boerhaav.* Chem. Part 2. p. 161.

Vitriolated TARTAR, *Tartarum Vitriolatum*. The chemists have sometimes boasted of great virtues, in what they call the magistery of this salt; this is the earth precipitated in the making of it. It is the opinion of some ingenious authors, that all fixed salts are produced by a blending together of the acid and alkaline salts, which the plants they are obtained from originally contained, with some earth. The making of this preparation of *Tartar* and vitriol, gives great strength to his opinion by means of this magistery; which shews, that an earth necessary to the cementing a mixture of an acid and an alkali into a neutral salt, may exist even in one of the principles themselves, though unseen by us; and that, as in the present instance, in so large a quantity, as not only to be sufficient for the combining the two volatile substances into a fixed one, but even to leave a remainder of it that was not necessary.

While the acid of vitriol is poured upon the dissolved salt of *Tartar*, or its oil *per deliquium*, for the making of this salt, during the great effervescence between the acid and the alkali, there is a precipitation made of an earth, for the separation of all which great care is to be had to the degree of saturation of the alkali with the acid. This earth afterwards may be severed by filtration. This earth is precipitated not out of the spirit of vitriol, but out of the salt of *Tartar*; and this experiment shews, that this fixed salt did originally contain that earth, which, according to the system of the formation of fixed salts out of volatile ones originally residing in plants, must necessarily be mixed with them, and which not being able to mix with the acid, is separated and thrown off in the conflict, in which the acid mixes itself with the rest.

This earth is what is pompously called the magistery of vitriolated *Tartar*; but it is very wrong to give that name to an earth, which has none of the properties of that or any other salt; and they greatly deceive themselves and their patients, who prescribe it instead of the salt itself. Its saline taste probably has induced them to think, that it possessed great virtues; but this is not innate, but adventitious, and the effect only of the fluid in which it was precipitated: It cannot but have some of the salts of that fluid hanging about it, when first made; but these may, by repeated washings, be carried wholly off, and the magistery will then remain a pure simple earth, and shew itself to be no other than that earth which may be properly called the earth of all fixed salts; and which, though necessary to give the salt of *Tartar* its form as a lixivial salt, yet being not necessary to it in its new form of a neutral salt, is deposited in the making it into that form.

It yet remains to be proved by more numerous experiments, that the fixed salts of plants owe that form only to a fixing earth, combining their two original volatile principles into a fixed mass; for if this be truly the case, there then needs no more to the volatilizing them again, but the divesting them of this earth. Phil. Trans. N°. 92.

TARTARHAN, a word used by some authors to express spirit of tartar.

TARTARUGA, in zoology, a name by which the Portuguese in America call a species of tortoise, known among authors by its Brasilian name *jurucua*. See the articles JURUCUA and TESTUDO.

TARTI *Lapis*, a stone mentioned by Ludovicus Dulcis, and some other authors, and said to be very beautiful, having all the colours of the tail of a peacock, and to have many medicinal virtues. It was probably some species of agate; but the short account given of it will not enable us to guess what particular kind.

TARTON *Raire*, in botany, a name used by some authors for the heath spurge, or that species of the thymelæa which is called *Sannamunda* in the catalogues of the materia medica. *Park.* Theat. p. 199.

TARUM, in botany, a name given by Pliny to the *agallochum sylvestre*, a species of aromatic plants. *Hofm.* Lex. in voc. See the article AGALLOCHUM.

TASIS, Τασις, in rhetoric, is used for the continuation of a period longer than the breath can hear. *Voss.* Ret. l. 4. p. 66.

TASCHENMUL, in zoology, a name given by authors to the *anas clypeata*, a species of duck, remarkable for the breadth of the end of its beak, and called in English, the *shoveler*. *Aldrovand.* de Avib. T. 3. p. 224. See the article SHOVELER.

TASTATURA, in the Italian music, the whole range of keys of organs, harpsichords, &c. See the articles ORGAN and HARPSICHORD, *Cycl.*

TASTE (*Cycl.*)—This is one of the most obvious characters of bodies, and much is to be judged from it of the nature of many things. Dr. Abercromby, in a treatise partly written on this subject, has carried his observations so far, as to lay down a set of rules for the judging of any plant, or other body, without knowing what it is, merely from its *Taste*, in regard to its virtues in medicine.

In order to judge of what he expressly means by the names of the several *Tastes*, it is proper to add the list of them, with some of the things to which they are applied.

Plants, fruits, &c. are either sour as the common sorrel, harsh as the medlar, austere or rough as the quince, sweet as the fresh juice of ripe grapes, fat and oily as the sesamum, bitter as gentian, or the wild cucumber, salt as common sea-salt, tart as garlick, or lastly, insipid as the gourd, or of some mixed *Tastes*, made of two or more of these.

The harsh or acerb things are cold, repelling and binding, hardly concocted, and they may all be known upon the tongue by their contracting or drying it. The austere or rough things differ from these only in degree, as being somewhat milder in *Taste*, and weaker in virtues.

The sour or acid things are always cooling; but this never to excess, by reason of their penetrating parts; this *Taste* is known by a biting on the tongue, but without any heat.

Sweet things are all nutritive; and, taking the word in its proper sense, it is they only that are so. Their sweetness arises from their neither being too hot nor too cold upon the tongue.

Fat things are moderately hot, and, on this account they all, in some degree, moisten and relax; but they also obstruct: they are known from the sweet things by filling and, as it were, anointing the tongue, without giving that sense of pleasure that the others do.

Salt things are astringent and detersive; the one quality they have from their earthy part, the other from their watery.

Bitter things may be very beneficial to the stomach; but, in improper cases, they may also do hurt. The pungent bitters, such as the elaterium, or wild cucumber, are all hurtful, unless rendered safe by other means.

Tart things are hot, and often bad for the head; but good in heavy and phlegmatic constitutions; they are known by their heat in the mouth.

Lastly; insipid things in general have no peculiar quality, but are cold and watery; they are generally hurtful to the stomach, unless mixed with hotter and spicy things. *Abercromb.* Nov. Medic. Clavis.

It is observed by Sir John Floyer, that the *Taste* is so good a judge for us, that all the chemical principles in plants may be discovered by it, before their distillation. All watery plants shew their phlegm, as well to the *Taste*, as by distilling; and in all dry woods, the *Taste* discovers the earth they contain, as well as a chemical analysis; by the mucilaginous and gummy *Taste*, and by the manifest oilyness in some plants, we distinguish their abounding in oil, as well as by the retort. The smell also helps us greatly in an extemporary judging of plants, and we are able to declare upon the spot, that all the aromatic plants, and all the fœtid ones, contain a large quantity of a volatile oil and salt. By the acrimony and pungency, we are well assured, that there is a volatile salt in plants; and, by the burning taste of others, we find that there is a corrosive salt in them. By a crude rough acidity, we distinguish the tartar or essential salt of plants to be in large quantity; but if the acidity be of a vinous smell, we observe that it is of a middle state of digestion, and may be called a vinous tartar, and distinguished from the first; but if the tartar have a pungent smell, then it is evidently a volatile tartar, or an acid acrid tartar.

The sweet *Tastes* are more numerous in plants, and more varied among themselves than any other kind. These, in general, shew their oil by thin slimy smoothness, and their tartar is evident in their extracts, as is very plain in the common liquorice juice.

The grass sweets, as the common dogs grass, and the like, have much essential salt, and a moderate portion of oil; and the rush, reed, horse-tail, and cats-tail, are all sweet and rough; some of these have more oil, and others more acid; and the most crude among them have more oil than tartar. The corn sweets, as barley, rye, wheat, oats, millet, and rice, have much oil and essential salt, and a little volatile; so bread, prepared of any of these, yields on analysis oil, and essential and volatile salt.

It is to be observed here, that fermentation and fire severally produce a volatile salt, where it was not before, by subtilizing and volatilizing the essential salt; and the slimy mealiness in corn supplies the oil. The goats beard and scorzonera kind, have the same principles as the grasses, much oil and essential salt. The sub-acrid sweets, as rampions, campanulas, trachelia, and the like, contain much oil and essential salt; but the acrimony in these plants shews that they have also a volatile salt, and that in no small quantity; though Lemery and the other chemical writers have not observed this.

The ferns, polypodys, and all that class of plants, contain much oil and essential salt; but the chemists in general have omitted to mention an acrid principle in all these, which bespeaks a volatile salt; and fragrancy is observed in some of the harts-tongues, which bespeaks a volatile salt also, and volatile oil, though hitherto unobserved.

All the leguminous slimy sweets have more oil than tartar; but all of them have a large quantity of both. Beans, Peas, and lentils, have also a volatile salt, as has also that strange fruit, eaten in Russia, and some other places, and called *lenticula aquatica* by some; but by the botanical writers, *tribulus aquaticus*; the other name belonging to the common duck-weed. The aromatic legumens, such as melilot, have an exalted oil, and volatile salt. The honeysuckle is said by Lemery, and the other chemists, only to have an essential salt and oil; but as there is a highly aromatic flavour, and great acrimony, there must be also a volatile salt.

These are some few instances, out of a vast number recited by the author, for the rest of which we refer to the paper itself in N°. 280 of the Transactions. Philos. Trans. N°. 299, p. 1160.

TASTO, in the Italian music, the touch or part of any instrument, whereon, or by means of which its notes are made to sound, be it on the neck, as lutes, viols, &c. which are called fixed and immoveable; or the front of organs, spinnets, or harpsichords, where the keys are disposed to raise the jacks, called moveable touches; and is properly no more than the finger-board of each.

Tasto Solo is often found in thorough basses, where it shews that the instruments accompanying, as the lute, organ, &c. are only to strike a single sound, from that place, till they find cyphers, or the words *accordo* or *accompanimento* placed in their part. These intimate, that the acc[illegible] are to begin again in this place.

TATA-*Youba*, in botany, a name used by some for the tree which yields what the dyers call the fustic, or yellow wood used in dying. *De Laet.* Ind. Occident. p. 603.

TATU, in zoology, the Brazilian name for the armadillo, or shell hedge-hog. *Grew*'s Muf. Reg. Societ. p. 17. See the article ARMADILLO.

We have several species of this creature described to us; but the most usual, is of the figure of a hog, and of the size of a large pig, and has a bony covering, which extends over the whole body, the head and the tail. This is composed of a number of very elegant scales, which have two junctures near the hinder part of the head, by means of which the creature is able to move its neck. On the back there are seven divisions, with a thick membrane between; and in all other parts of the body the shell is whole. The legs, so far as they come in sight, are in the same manner defended by a bony covering, in form of a shell, but thinner than that of the back; the belly has nothing of this covering, but is beset with a few whitish hairs, which grow out of very observable and eminent pores. The junctures of the head and back have also the same sort of hairs; the head is like that of a hog, the nose sharp, the eyes small, and set deep; the ears short, naked, and brown; the teeth are but small, and are in number eighteen in each jaw. The feet are made like hands; each has five toes, and the nails are round. Its colour is a sort of reddish tawny. It digs up the ground with its nose, in the manner of a hog, but much more nimbly; the tail is thick at the insertion, and tapers to the extremity. The creature feeds on roots and fruits, as potatoes, melons, and the like; but will eat meat also if it comes in its way. It is usually found in dry places; but sometimes in watery ones. *Ray*'s Syn. Quad. p. 233.

TATU-*Apara*, in zoology, the name of a creature of the armadillo kind; but differing from the others in many particulars: Its head is oblong, and of a pyramidal figure; its ears are small, short, and roundish; and its feet, as well the fore ones as the hinder ones, have each five toes. The fore legs are about three fingers long, the hinder ones five; the tail of a pyramidal figure, and little more than two fingers breadth long. It is covered with a shelly coat of a foot long, and eight fingers wide; it is smaller at both ends than in the middle; and is convex on the outside, and concave within. In the middle, or a little toward the fore end, it has four junctures, which are placed transversely, and by means of which it can, at pleasure, either expand its shell, or contract it together into a round figure. The whole crust is composed of pentangular pieces, very nicely fitted to one another, and the series of these between the commissures are parallellograms. The whole is composed of yellowish scales joined by an extremely tough skin.

When the creature would sleep, or when it is afraid of being taken up, it contracts its crust into a round figure; and hiding its

whole body within, it might sooner be taken for a sea-shell than a land animal. Its flesh is eatable, like the rest of this kind; and its food is the same as theirs. *Ray's* Syn. Quad. p. 234. See Tab. of Quadrupeds, N°. 21.

TATU-*Mustelinus*, the *weasel-headed armadillo*, in zoology, the name of a small animal of the armadillo kind; its head is about three inches and an half long; his forehead two inches and a half broad, and very flat; the end of his nose half an inch; his eyes small; his ears very distant from one another; his body eleven inches long, and about six broad; and his tail five inches long, and not tapering to so extreme a thinness at the point as that of the common armadillo, but a fifth of an inch over. His fore leg two inches and a half long, and three quarters of an inch broad, with five toes; his hinder foot something larger, and with the same number of toes. His head, back, sides, and tail, all covered with a shelly armour. His breast, belly, and ears, all naked. *Grew's* Musæum Reg. Societ. p. 19.

TATU-*Porcinus*, in zoology, the name of the pig-headed armadillo, a creature of about twelve or fourteen inches long.

Its nose is shaped like that of a pig, with four toes on its fore feet, and the hinder foot thicker, and having five toes; his tail eleven inches long, and extremely small at the extremity. Its head, legs, back, and tail, are all covered with a shelly armour. The fore part of his tail covered with eleven shelly rings; his thighs, breast, belly, and ears, all naked; his eyes black, round, and very small. His teeth are twelve in each chap, and no thicker than large needles. *Grew's* Musæum Reg. Societ. p. 18.

TATUETE, in zoology, the name of a species of *Tatu*, or armadillo, smaller than the common one, and differing also in many other respects.

Its head is small and sharp; its ears long and erect; its tail about three fingers long; and its legs much longer than in the common larger kind; but its most signal difference is, that it has only four toes on the fore feet, and five on the hinder ones; the two middle ones are the longest on the fore feet, and the three middle ones on the hinder; its whole length is about seven fingers breadth; its forehead and whole body are covered with a coat of armour, which stands out at the sides so far, that the creature can, at pleasure, draw in its head and legs under it; the armour of the back consists of nine pieces nicely joined to one another; the tail is coated in the same manner, and has likewise nine junctures, and ends in a point. It is of an iron colour on the back, and whitish at the sides; its belly also is whitish and naked, except for a few hairs.

The flesh of this is accounted more delicious than that of any other creature of this kind, though they may all be eaten. *Ray's* Syn. Quad. p. 234.

TATULA, in botany, a name used by Clusius, and some other authors, for the stramonium, or thorn-apple. *Ger.* Emac. Ind. 2.

TAVACCARÆ, in the materia medica, the name by which many authors call the *coccus maldiviæ*, or maldive nut. *Piso*, p. 203.

TAULACUM, in natural history, a name given by the people of the East Indies to a species of orpiment which is very common with them.

It is of a dirty yellow colour, and is composed partly of an irregular mass, partly of fine flakes, like scales of fishes. These are of the best colour. The whole mass, on being exposed to the fire, burns, and emits copious fumes; but it does not melt readily. After it has been several times calcined, the Indians give it internally in intermittent fevers, with safety and success. *Woodw.* Catal. Foss. vol. 1. p. 24.

TAUREA, among the Romans, a punishment inflicted by whipping with scourges made of bulls hides. *Pitisc.* in voc.

TAURIA, Ταυρια, in antiquity, a festival in honour of Neptune. *Pott.* Archæol. T. 1. p. 432.

TAURILIA, among the Romans, games in honour of the infernal gods. They were otherwise called *ludi taurii*. See *Pitisc.* in voc. *Ludi*.

TAUROBOLIUM, or TAUROBOLION, among the antients, sacrifices of bulls, which were offered to Cybele, the mother of the gods, to render thanks to the goddess of the earth, for her teaching men the art to tame those animals, and fit them for labour. See *Pitisc.* in voc.

TAUROCOLLA, *Bull-glue*, a sort of glue much used among the antients in works that required strength, being accounted far stronger than any other kind. It was made by boiling down the ears and genital parts of a bull in water.

TAURUS, (*Cycl.*) *Bull*, in zoology, the male of the ox-kind. See the articles BULL and BOS.

TAURUS, in ornithology, a name given by the antients to the bittern, or butterbump, from its imitating the roaring of a bull in its noise.

TAURUS *Æthiopicus*, the *Æthiopian Bull*, an animal described in a very remarkable manner by Pliny.

He indeed calls it the Indian *Bull*, and has led Solinus into the same error; but all the authors whom he quotes, and from whom he has transcribed his account, calling it the *Æthiopian Bull*, we may be assured that was its proper country. Agatharcides is the oldest author who has described these animals; he says, they lived only in Æthiopia, and that they were greatly larger than our oxen, and of a yellowish or tawny colour, and were swifter of foot than almost any other animal. Strabo, and all the other authors of credit, also mention this animal; but the descriptions they give of it are, in some particulars, carried too far into the marvellous.

They tell us, that all its hair stands the wrong way, and makes it the roughest animal, to appearance, in the world; and that its head is, as it were, all mouth, the opening of the mouth reaching from ear to ear. The horns, they say also, were very strong and sharp, and were moveable, so that the creature could turn them in any direction, at pleasure, to take aim at the proper part of the creature he would gore; but that as soon as he had placed them in this direction, they became firm and unalterable in it by any force, till he chose to alter the position himself. They, add, that its back, or hide in general, was of the hardness of flint, and turned away all sorts of darts. This creature hunted and fed upon all other animals, according to the accounts of the same authors, and could itself never be taken but by pitfalls; and that when it was thus trapped, and let down into a hole or pit, out of which it was impossible to get out, its fury generally killed it in a few minutes, without any wound. These are the wonderful things related by the antients of this animal; but they are so contrary to the course of nature in the ox kind, that we may very justly rank them among the other miraculous animals, such as the mantichora; and the vermis cæruleus, of sixty or seventy foot long. See the articles MANTICHORA.

TAXUS, the *Yew*, in botany, the name of a genus of trees, the characters of which are these: The flower is of the amentaceous kind, and is composed of a number of apices, usually shaped like mushrooms; these are the male flowers; the embryo fruit appears in different parts of the tree, and finally becomes a red berry, of a hollowed or cup-like shape, juicy, and containing a seed. There are also sometimes, on the same trees with these, dry fruits, in shape of acorns; the seed being enclosed at its bottom, not by a juicy berry, but by a dry cup.

There is no other known species of the *Yew*, beside the common kind; but that is sometimes found with variegated leaves. *Tourn.* Inst. p. 589.

TAXUS, in zoology, the name of the *Badger*, called in some parts of England, the *brock*, the *gray*, and the *pate*. The Greeks had no name for this animal, unless their *hyæna* was the same creature. See the article HYÆNA.

Authors who have described this animal, have all made two kinds; the *Taxus-Caninus* and *Taxus-Porcinus*, the dog and the hog-*Badger*. The last of these is our common kind; and 'tis indeed doubted whether there be any such animal as the authors describe under the other name.

The body of the *Badger* is short and thick; its neck very short, and its hairs long, and very rigid, and stiff like hog's bristles. Those on the back are of a pale yellow near the root; brown or black in the middle, and at the extremities yellowish again; so that the creature appears, upon the whole, of a mixt colour, or what we call grey, on the back. The sides and belly are covered with hairs, which are all over of a pale yellowish hue; and the legs and shoulders, as also the belly, are wholly black. It has a broad white line from the top of the head to the nose; and on each side of this a very regular pyramidal black mark reaching up to the ears; and below these the jaws are whitish, that the creature's face looks very oddly variegated. Its eyes are small; and its snout wholly like a dog's. The teeth are like those of a dog also; and the legs short; its fore feet have sharp claws, with which it digs itself burrows in the earth. Its face is very like that of the fox, being broad at the top of the forehead, and sharpening to a point at the nose, so as to appear triangular in shape; and its cheeks are tumid, and furnished with strong muscles, whence it bites very hard. It feeds on insects and small animals, and on the roots of vegetables. We have them in many parts of England, particularly in the counties of Essex, Sussex, and Warwickshire. *Ray's* Syn. Quad. p. 185.

The *Badger's* skin is of some use in commerce. Their fat is sold by the druggists, as a remedy against disorders of the kidneys, and the sciatica; and their hair for the making pencils for painters and gilders. *Savar.* Dict. de Comm. p. 354.

TEA (*Cycl.*)—*Tea* is extolled by the orientals as the greatest of all medicines; moderately and properly taken, it acts as a gentle astringent and corroborative; it strengthens the stomach and bowels, and is good against nauseas, indigestions, and diarrhœas. It acts also as a diuretic and diaphoretic. The immoderate use of it, however, has been very prejudicial to many, who have been thereby thrown into the diabetes.

TEALE. *Summer* TEALE, in zoology. See the article CIRCIAS.

TEARS (*Cycl.*)—Dr. Vaterus is of opinion, that the *Tears* come from the white lines seen on the inside of the palpebræ, described by Meibomius. He observed two small ducts, besides the common nasal duct, from the lacrymal sac into the nose; one of them opened into the upper part of the nose; the other opened into the *antrum maxillare*. Miscel. Berol. Tom. 4. par. 3. §. 5.

TEASEL,

TEASEL, *Dipsacus*, in botany. See the article DIPSACUS.

Beside the common wild species of this plant, there is a large kind of it, the heads of which are of singular use in raising the nap upon woollen cloth, for which it is propagated in great quantities in many parts in the West of England. It is to be sown in March, on a dry soil; a peck of the seeds are sufficient to sow an acre: The plants being come up, must be houghed up first to six inches, and some time after to a foot asunder every way; and for the first summer the ground must be kept carefully cleared from weeds. The second year after sowing, the plants shoot up to heads, which are fit to cut in August, and tied up in bundles, and dried. The common produce of an acre of land is about a hundred and sixty bundles, which are sold at about a shilling a bundle. Some people sow carraway among their *Teasels*, but it only damages both. *Miller's* Gardener's Dict.

TEBET, or THEVET, the fourth month of the civil year of the Hebrews, and the tenth of their ecclesiastical year. It answered to our moon of December, and has but 29 days. The second day of this Month is the last of the octave of the dedication of the temple, after it was purified by Judas Maccabeus. V. 1 Macc. iv. 59. John x. 22. *Calmet*, Diction. Bibl. in voc.

TECHNICAL *Chemistry*. See CHEMISTRY.

TECOLITTROS, in natural history, the name of a gem, otherwise called *Syriacus lapis*, and *Judaicus lapis*, good for dissolving the human *calculus*. See the articles SYRIACUS and JUDAICUS.

It has this name from τηκω, I dissolve, and λιθος, a stone; because it dissolves stones. *Hofm.* Lex. univ. in voc.

TEE, in the manege. See the article BREAST-*Plate*.

TEETH (*Cycl.*)—When the *Teeth* are subject to be overspread with a black or yellow crust, it is a very good method to rub them well every day with a mixture of tincture of gum lac, honey of roses, and spirit of vitriol, which will not only whiten the *Teeth*, but render the gums more firm.

The world is fond of tooth powders, and a moderate use of them may do service; but the daily rubbing with them does more harm to the *Teeth* than wholly neglecting them. Powders of this kind may be prudently used once in six or seven days, and will render the *Teeth* white and splendid. The common powders, prepared for this purpose, are too hard, and wear away the gums; softer substances should be employed, and when the gums are f d, a few drops of some acid spirit be added to the powder. The following is a very efficacious and safe powder: Take chalk in powder, myrrh, burnt hartshorn levigated, and Florentine rice root, of each two drams. Spirit of salt, six drops; mix all into a powder. *Heister's* Surgery, p. 457.

The common trick of mountebanks, and other such practisers, is to use various washes for the *Teeth*, the sudden effects of which, in cleaning and whitening the *Teeth*, surprize and please people; but the effects are very pernicious. All the strong acid spirits will do this. As good a mixture as any thing can be, on this occasion, is the following: Take plantane water an ounce, honey of roses two drams, spirit of salt ten drops; mix the whole together, and rub the *Teeth* with a piece of linnen rag dipped in this, every day, till they are whitened. The mouth ought to be well washed with cold water, after the use of this or any other acid liquor; and indeed the best of all *Teeth*-washes is cold water, with or without a little salt; the constant use of this will keep them clean and white, and prevent them from aching. *Heister's* Surg. p. 457.

Animalcules in the TEETH. No animalcules are to be found in any of the juices of the body, except the semen of male animals; and consequently the saliva affords none: yet great numbers, and those of different kinds, may be discovered in the white matter sticking between the *Teeth*, if it be picked out with a pin or needle, and mixed with a little rain water, or spittle, without bubbles, and applied before the microscope; and sometimes they are so incredibly numerous, and full of motion, that the whole mass seems alive. The largest sort are of an oblong oval figure, and pointed at one end; these move along very swiftly; but of these there are but few. There is another sort like these, in figure, but much shorter and smaller; these have a peculiar motion, being always running in an undulated or spiral line. A third sort are roundish, and so minute, that a grain of coarse sand is equal to a million of them in bigness: These move so very nimbly, that their shape is not easily distinguished; yet they appear like large swarms of gnats.

Some, or all of these three kinds, may be found between the *Teeth* of persons of all ages and sexes, especially between the grinders, and that though the mouth be washed ever so constantly. But from the *Teeth* of people who are more careless, there may usually be taken another sort of animal, in the shape of an eel or worm; these move backwards and forwards with great agility, and force their way through the clusters of smaller animalcules with great impetuosity; they move their bodies also into several bendings in their progressions. Beside these, there are also several other species of animalcules, whose motion is so slow and languid, that it requires great attention to be sure that they have life. They all die if a little vinegar be put to them; whence it seems a very proper method, to wash the mouth with vinegar, in order to destroy them. *Baker's* Microscope, p. 167.

Clenched TEETH. The *Teeth* are in some cases found so closely and firmly shut, that they cannot be opened sufficiently to give the person liberty to eat or speak. This generally arises from a spasm or cramp of the elevating muscles of the lower jaw. The cause of this spasm is various; sometimes it arises from a wound or blow, even from injuries of the nerves and tendons in different parts of the body; as after an amputation of an arm or a leg. Sometimes also, it is owing to an inflammation of the fauces themselves.

When this disorder arises from a wound, the first thing to be done is to search whether there be not some extraneous body left in it, which excites these spasms; if this be found to be the case, they always cease immediately, upon the pulling out such offending matters. If there be no such bodies in the wound, and medicines give no relief to the convulsions, you may be sure that some nerve is wounded; and the method then is to cut the nerve in two, if that may be done, and immediately the spasms will cease. Sometimes however, the nerve lies inaccessible, or cannot be divided without danger of the patient's life; which is a very deplorable case, and generally brings on a necessity of amputating the limb. These spasms when from amputations are less to be dreaded, since they generally go off on untying the ligatures about the vessels, and taking away the vitriol or other caustic applied to restrain the hæmorrhage.

When an inflammation of the tonsils or jaw excites this spasm, these are to be treated in the common method; and the cause being removed, as in the other cases, the effect will cease. But if this disorder be of so long continuance as to threaten the patient with starving, he is to be supplied with broths and other liquid food, which may be sucked through the *Teeth*.

The surgeons have an instrument, which they call *speculum oris*, made to force open the mouth on these occasions, and some advise the breaking out a *Tooth*, to give room for food and medicines; but both these practices are wholly to be rejected, as making the spasms more violent and obstinate. *Heister's* Surg. p. 455.

Hollow TEETH. The *Teeth* which are hollow and decayed are usually carious, and admit some parts of the food into their cavities, which by degrees putrifies, becomes acrimonious, and not only farther destroys the *Teeth* themselves, but irritates the internal periosteum and nerves of the *Teeth*, so as often to cause intolerable pain. Many methods have been contrived for relief in these cases: One is to clean the cavity, and then fill it up with mastick as often as there is occasion; and another is the filling up the cavity with a piece of lead or gold. The cavity may also be filled at times with oil of cloves, and the like, or cauterized with a red hot iron; this generally proves a lasting remedy, and is attended with very little additional pain, if carefully performed, and no part of the mouth burnt. If all these methods fail, the last relief is the taking out the *Tooth*, and afterwards replacing it again. *Heister's* Surg. p. 458. See the article TOOTH-*Drawing*.

Supernumerary TEETH. These are sometimes the cause of great disorders, and may, without careful examination, be mistaken for exostoses or schirruses of the palate. See Med. Ess. *Edinb.* Vol. 5. art. 16.

Mark of TEETH, in the manege. See the articles MARK and EYE *of a Bean*.

TEETH *of Fish*, *Dentes Piscium*. The *Teeth* in the fish kind are so very various in their shape, and also so variously disposed, that they make a very notable mark of distinction among the several genera.

As to situation, they are, 1. sometimes placed only in the fauces and orifice of the stomach, the rest of the mouth being entirely smooth: We have examples of this in the cyprini, and the ammodytæ or sand-eels, and many other fish. 2. In some the *Teeth* are placed only in the jaws; the tongue, the palate, and the inner part of the mouth being smooth. 3. In some they are placed in the jaws, and on the tongue, the rest of the mouth being smooth. 4. In some the tongue, the palate, and the jaws have *Teeth*, but the back part of the mouth is smooth; the herring has them disposed in this manner. 5. Some have the fauces, tongue, palate, and jaws all beset with *Teeth*, as the salmons, &c. 6. Some have them in the fauces and jaws only, the tongue and the palate being smooth: This we have instances of in the pleuronecti. And finally, 7. Some fishes have *Teeth* in the jaws, fauces and palate, and the tongue only remains smooth: This we see in the mackrel, &c. And all these are very essential marks and distinctions never varying in the same fish, and may serve as characters much better than the colours and other such more obvious, but less essential things, remarked by the old authors.

The differences in the shape of the *Teeth*, are as many as those in their situation, and may serve to as much purpose in their distinctions. 1. They are in some acute and sharp at the ends; this is the case in most fish. 2. In some they are obtuse, and as it were flatted at the end, as in the cyprini. 3. In some fish they are of a conic shape, as those in the

the upper jaw of the thymallus. 4. They are in fome compreffed or flatted at the fides, as in the gadi and eloces. 5. They are fmooth and even at the fides, as in the greater part of fifhes: Or, 6. They are ferrated or notched at the fides, as in the fhark kind, and fome others. 7. They are in fome ftrait, as in the common acus or needle-fifh, of Oppian And, 8. They are fometimes crooked inwards, as in the ofmeri, *&c.* Finally, they are fometimes convex on one fide, and flat on the other, as in the caprifcus.

The *Teeth* of fifh differ in proportion alfo. 1. In fome they are all of the fame fize in the fame fifh, as in the cottus, *&c.* 2. In fome they are of very different fizes in the fame mouth; we have inftances of this in the pike, the lucioperca, and many of the gadi. 3. They differ alfo in number and arrangement, for in fome fifh they are placed only in fingle rows in the jaws, and other places allotted for them; but in others they are aggregated into feveral rows; the firft is the cafe in the falmons, *&c.* the other in the cotti, and other fifh. *Artedi* Ichthyolog.

Mammoth's TEETH. See the article MAMMOTH's *Teeth.*

TEFTERDAR, the name of an office of dignity in the Eaftern nations. In Ægypt he is the lord high-treafurer of the tribute paid out of the lands to the Grand Seignior. He is named for a year by the Porte; but is generally continued in his office many years. This office is fometimes given to one of the poorer Beys, to help him to fupport his dignity; and frequently to a quiet one, who is not likely to enter into intrigues. For one party never cares that a ftirring man of the oppofite party fhould be invefted with an office of this dignity. *Pocock's* Egypt. p. 165.

TEGS, a term ufed in fome part of the kingdom by the farmers, to exprefs lambs of a year old.

When a flock of ewes and lambs are turned into a turnepfield, the young lambs of three weeks old will immediately fall to eating the turneps, and fcoop them very prettily; but thefe *Tegs* will not touch them for feveral days. They ufually ftay till almoft ftarved to death before they begin, but when they have begun they foon grow fat.

TEGULA *Hybernica*, Irifh *Slate*; a ftone of the flate kind, fo ftrongly impregnated with alum, as to deferve the name of an alum ore. It is often likewife found to contain a large portion of vitriol.

It is found in great abundance in many parts of Ireland, as alfo in feveral of our own counties. Many prefcribe it in powder as a ftyptic, in hæmorrhages of all kinds, with fuccefs; but, perhaps, it would be full as prudent for the perfon who knows to what falt or falts it owes this virtue, to give thofe falts alone, in a dofe that he can depend upon, and without the load of earthy matter, which is always to be found in this powder. Vid. *Hill*, Hift. Mat. Med. p. 257. feq.

This fubftance beaten to powder and infufed twelve hours in water, will impart fo much of the vitriolic falt it contains to the water, that being mixed with an infufion of galls the liquor will become reddifh, in the fame manner that the medicinal waters of many parts of this kingdom do, which not containing vitriol enough to make ink with, the infufion of galls yet turn reddifh with it. It is hence not improbable, that many of thefe waters owe their virtues to this very fubftance. This kind of flate being very frequent in many parts of the kingdom, at different depths under the furface; and it being not hard to conceive, that a bed of water paffing through a large ftratum of it, may acquire thofe virtues in its paffage that we find common water, in our own experiments, becomes poffeffed of by a few hours cold infufion.

This on being calcined, in order to try whether it be an iron ore, does not after burning, anfwer to the magnet; fo that it feems to contain no iron at all in the ftate of metal. But this is obfervable, that it calcines to a fort of ochre, becoming of a yellow colour, and marking as ochres will do. The yellow of this flate being burnt too far becomes of an orange-colour, exactly like the fediment of yellow matter, which we find about the ferruginous waters; and this fediment is hence efteemed by fome to be the remains of this flate diffolved by the water, rather than iron ore. It is even doubted by fome, whether the yellow ochres are indeed iron ores, or not; for many of them will not anfwer to the magnet, even after feveral days and nights continued calcination. It is indeed very certain, that all the naturally red ochres do contain iron, all of them having particles that anfwer to the magnet after a much flighter calcination than this given in vain to the yellow kinds. Phil. Tranf. N°. 243. p. 272.

TEICHOPŒUS, τειχοποιος, among the Athenians, an officer who had the care of the city walls; their number was the fame with that of the tribes, every tribe having the choice of one. *Potter*, Archæol. Græc. T. 1. p. 84.

TEITEI, in zoology, the name of a Brafilian bird called alfo *guiranheemegeta*, and *guroundi.*

It is of the fize of our red-breaft. Its beak is black, thick, and fhort; its head, the upper part of its neck, its wings, its back, and its tail, are of a bluifh black, fhining like the fineft high-polifhed fteel. Its throat, the lower part of its neck, its breaft, and its belly, are yellowifh. Its legs and feet are brown. The female is of the fame fize with the male, but differs in colour, being variegated with green, yellow, and grey. It fings very fweetly, and is kept in cages, five or fix together in the fame cage. *Marggrave's* Hift. Brafil.

TEJUGUACU, in zoology, the name of a fpecies of lizard, common in the Brazils, and called alfo *Temapara.*

It much refembles the iguana, in its general figure, but differs from it in that its whole body is black, only variegated with fome white fpots; its tail is thicker at its origin, it has not the feries of ferrated fpines, which the iguana has running all down its back. In the hinder feet the outer toe is alfo more remote from the reft, and fhorter; and it has a long red bifid tongue; and the animal can vibrate it an inch or more out of its mouth, in the manner of fnakes; but it makes no hiffing. It lives principally on the fucking of eggs, but it is capable of bearing hunger a long time; Marggrave having kept one alive feven months without eating. This fpecies afforded alfo a certain teftimony to that author, of the reproduction of the tail when cut off. *Ray's* Syn. Quad. p. 265.

TEIUNHANA, in zoology, the name of a fmall American lizard. It is about the thicknefs of one's little finger, and has a fharp nofe. Its tail is very flender, fix fingers breadth long, and terminates in a point almoft as fharp as a needle. Its head is covered with fcales; its back, fides, and legs, with a tender fkin as foft as fattin to the touch; and its tail is covered with extremely minute fcales, of a fquare figure. The throat and belly are covered alfo with fcales of the fame fhape, but larger. Its head is wholly brown; its back and fides are variegated with ftreaks of brown and green, and with feveral beautiful longitudinal feries of green and black fpots. The throat and belly are white; but they are beautifully variegated with fpots of a fine deep blood-red. The tail is of a dufky yellow or wax colour on the upper part, and of a pale and beautiful flefh colour underneath. *Ray's* Syn. Quad. p. 267.

TELAMONES, among the Romans, figures of men fupporting the out-jetting of cornifhes in architecture. The word, according to fome, is derived from the Greek τιλαμων, from τιλαω, or τλαω, I bear.

Among the Greeks they were called *Atlantes*, Ατλαντες, which comes from the fame word ταλαω, or τλαω, by the figure metathefis. *Pitifc.* in voc.

TELAMONES, is alfo ufed by the chirurgical writers fometimes for lint, and fometimes for the fillets or bandages, which they apply over their dreffings.

TELE, Τελη, among the Athenians, thofe revenues that were brought in by lands, mines, woods, and other public poffeffions, fet apart for the ufe of the common-wealth; as alfo tributes paid by fojourners and freed-fervants, and the cuftoms laid upon certain trades and goods. See *Potter* Archæol. Græc. T. 1. p. 80.

TELEOLOGY, the fcience of the final caufes of things. This is an ample and curious field of enquiry, though pretty much neglected by philofophers. *Wolf.* Difc. Prælim. Logic. §. 85.

TELEPHIUM *Orpine*, in botany, the name of a genus of plants; the characters of which are thefe: The flower is of the rofaceous kind, confifting of feveral petals, arranged in a circular form, and contained in a cup, confifting alfo of many leaves. The piftil arifes from the cup, and is finally converted into a triangular fhaped unicapfular fruit, containing a number of fmall and roundifh feeds. To thefe marks it may be added, that the leaves ftand alternately on the ftalks.

The fpecies of *Telephium*, enumerated by Mr. Tournefort, are thefe: 1. The common wild *Orpine*. 2. The American *Orpine*, with purflain leaves. 3. The red-flowered houfeleek-leaved fea *Orpine*. And, 4. The white-flowered houfeleek-leaved fea *Orpine*. *Tourn.* Inft. p. 248.

TELESCOPE (*Cycl.*)—Mr. Caleb Smith thinks that catadioptical *Telefcopes* might be formed with fpeculums of glafs, inftead of metal; and makes feveral obfervations as to remedying the diforders caufed by the different refrangibility of the rays of light. See Phil. Tranf. N°. 456. fect. 8.

TELETÆ, among the antients, were folemn rites performed in honour of Ifis. *Pitifc.* in voc.

TELICARDIOS, in natural hiftory, the name given by fome authors to a ftone found in the fhape of a heart. It owes this figure to its having been found in the fhell of fome large bivalve of the cockle kind; and is more ufually known among authors under the name of *Bucardites*. See the article BUCARDITES.

TELIPHANO, in botany, a name ufed by fome authors for the doronicum, or leopard's bane. *Ger. Emac.* Ind. 2.

TELLA *Sagrum*, in natural hiftory, a name given by the natives of the Eaft-Indies, to a kind of earth which they ufe externally to dry up ulcers, and internally in cafes of coughs and colds. It is of the nature of the finer clays, and is found at the bottoms of fome of their rivers.

TELLA *Pafhnum*, in natural hiftory, a name given by the people of the Eaft-Indies to a kind of white arfenic, or rats-bane, found native among them.

It is well known to be a fatal poifon, and ufed to deftroy vermine. It lies in the cliffs of rivers among ftrata of ftone in

in large white irregular lumps, when held to the fire it emits copious fumes smelling strongly of garlick and sulphur, but it does not readily melt or run.

TELLINA, in natural history, a sea-shell, by the latest writers on these subjects, referred to the genus of muscles. See the article MYTULUS.

These shell-fish do not naturally live on the surface of the bottom of the sea, but bury themselves in the mud or sand, in the manner of the chamæ, keeping a communication with the water above by means of the same sort of tubes or pipes as those fish are possessed of; but as the tubes of the *Tellinæ* are very short, the fish can only bear to be buried to a small depth.

When the water covers the bottom where they lie, they remain always buried in the sand; but when the sea in its ebb leaves the place dry, they very often come out of their holes, and are seen lying flat upon their sides on the sand; whether this be to take in fresh air, or, which seems more probable, to seek after the water which has abandoned them. They seem also to go far in search of it, for it is common to see them at a foot distance from their hole, with the furrow marked by their progression all the way behind them, from the aperture of their cell to the place where they are found. They perform this motion by means of a sort of foot, such as the chamæ, the sourdon, and many other bivalve shells have; but the leg to which this foot is fastened, is in this species very short, and not capable of any great extension. Mem. Acad. Par. 1710.

TELON, a name given by the chemists to fire.

TELONÆ, τελωναι, among the Athenians, farmers of the public revenues; for the severity with which they were handled, in case they failed, see *Potter* Archæol. Græc. l. 1. c. 14. T. 1. p. 81.

TELINO, a name given to the *Urogallus*, or great cock of the mountain. See Tab. of Birds, N°. 25. and the article UROGALLUS.

TELONIUM, among the Romans, is used to denote a customhouse, or place where the toll was collected. See *Pitisc.* in voc. and THELONIUM, *Cycl.*

TEM, or *brown* TEM, in zoology, the name of a water-fowl of the larus or gull-kind, called by Aldrovand *Larus cinereus minor*.

It is but a small species. Its back and wings are of a pale grey, with some faint admixture of bluish; and the longer feathers of the wings are black within. The beak is very small, somewhat crooked, and black. The back part of its head also is black. All other parts of the body are of a fine white. The feet are webbed, and the legs are yellow. *Ray's* Ornithol. p. 268.

TEMACHIS, in natural history, the name of a genus of fossils, of the class of the gypsums; the characters of which are these. It is of a softer substance than many of the other genera, and of a very bright and glittering hue.

The name is derived from the Greek τεμαχιον, *frustulum*, a small irregular fragment; the bodies of this genus being compofed of an assemblage of multitudes of irregular flaky fragments, as are all the gypsums; but no genus of them so visibly so as these.

There are but three known species of this genus: 1. A soft shining green one. 2. A soft white one, of a marbly appearance. And, 3. A pale brown glossy one. The first is found in great plenty on the shores of rivers in the East-Indies; and though not known as a substance that would make a plaster by burning, is given internally in nephritic cases, being powdered without calcination. The second is found in many parts of Derbyshire, and is used for burning into plaster for stuccoing of rooms, and casting statues, &c. And the third is found in Germany; and, beside its common uses in stuccoing and casting, is in great esteem among the metallurgists and assayers, for the making either singly or in mixture with bone-ashes, their tests. See the article TEST.

We have not this species in England so far as is yet known. *Hill's* Hist. of Foss. p. 113, 114, 115, 116.

TEMAPARA, in zoology, the name of a peculiar species of lizard, called also *Tejuguacu*.

It approaches much to the nature of the *Iguana*, but is black spotted with white. See the articles IGUANA, and TEJUGUACU.

TEMBUL, in botany, a name used by some authors, for the plant called *betle*, an herb the people of the East-Indies are fond of chewing. *C. Bauhin.* pin. p. 410. See the article BETLE.

TEMELO, in zoology, a name used by some for the fish called in English the *greyling*, and in some places the *umber*.

It is a truttaceous species, known among the writers in ichthyography under the name of *Thymallus*. *Willughby's* Hist. Pisc. p. 187. See the article THYMALLUS.

TEMPATLAHOAC, in zoology, the name of a broad-billed bird, of the West-Indies, described by Nieremberg; and by him esteemed a species of duck.

It is of the size of the common duck. Its head and neck are green, black and purple, and very bright and shining like the neck of the peacock. The body is of a brownish yellow, and it has two large spots of white on each side near the tail. The tail is white all round the edges, and is of the same marks and colours with the peacock's, but black underneath. It is common on the lakes of Mexico, and is a good eatable bird. *Ray's* Ornithol. p. 299.

TEMPERAMENT, or TEMPERATURE, (*Cycl.*) in music. Mr. Chambers, under this head, informs us, that the *Temperament*, or *Temperature*, denotes a rectifying or mending false and imperfect concords, by transferring to them part of the beauty of the perfect ones. This he took from Mr. de Fontenelles, in the Hist. de l'Acad. des sciences, 1701.

But this requires a fuller explanation; for though it be true, considered in one light, that a *Temperature* corrects some false concords; yet it is no less true, that, in other respects, it spoils and falsifies both perfect and imperfect concords, and renders discords more harsh than they would otherwise be, if the intervals were justly taken. To explain this, we must consider that all the intervals are founded on the primary proportions arising from the numbers 2, 3 and 5, that is, if we do not exceed the compass of an octave, $\frac{2}{1}$, $\frac{3}{2}$ and $\frac{5}{4}$. See the article INTERVAL.

The nearer we come in practice to the true intervals, the more perfect the melody and harmony will be; and it is certain, that the human voice, and some instruments, as violins, &c. which have no stops nor frets, will execute music to a great degree of exactness; but the case is not the same with fixed or fretted instruments, as harpsichords, organs, lutes, viols, &c. Accuracy is here impossible, unless we would content ourselves with always playing in the same key, without any transition or transposition whatsoever. In this case, indeed, the harpsichord or organ might vie with the accuracy of the voice or violin. For instance; if we were to compose or play in the key of C, then we might make the several intervals of that key, to be in the following true proportions, $1 \cdot \frac{9}{8} \cdot \frac{10}{9} \cdot \frac{16}{15} \cdot \frac{9}{8} \cdot \frac{10}{9} \cdot \frac{9}{8} \cdot \frac{16}{15}$. that is in whole numbers

C.	D.	E.	F.	G.	A.	B	C.
24	27	30	32	36	40	45	48.

and the instrument, tuned in this manner, would perform any piece of music in C, justly composed, with great beauty and exactness, I here take for granted, that every key, fundamental note, or sound, ought to have its true fifth and fourth, and that these ought also to have their true fifths and thirds.

Now this being premised, it will presently appear, that in making any transposition or transition from C, we shall find some false concord. Thus, for instance, if we proceed to G, and consider it as a key, or fundamental sound, we shall have the following series of numbers for the octave of G, *viz.*

G	A	B	C	D	E	F	g
36	40	45	48	54	60	64	72.

But here the interval between 40 and 54 is false, being a comma too much, for the second of a key must make a true fifth with the fifth of the same key. In like manner, if we were to proceed from C to A, as a new key, we should find the following series for the octave of A,

A	B	C	D	E	F	G	a
40	45	48	54	60	64	72	80,

where the interval between A 40 and its fourth D 54 is false, being too great by a comma. If any other transition were examined, we shall always find some note false; as in F, the sixth would be redundant by a comma. And in D the fifth would be deficient by a comma. All which shews the impossibility of truth and exactness of music on fixed instruments. Yet as these instruments have their use and convenience in some respects, it was proper to endeavour to find out a method of making them tolerable.

It has been observed under the head INTERVAL, that the tone major exceeds the tone minor by a comma. Their difference is necessary for the truth and perfection of music; but yet if these tones were rendered equal, the ear would not be offended. And this has suggested the means of tempering fixed instruments. If we were to make all tones equal to the tone major, as some imagine the antients did, then we should find the ditonus or third, exceeding a true third major by one comma, which would be intolerable. In like manner, if all tones were to be minor, we should have thirds major defective by a comma, which would also be intolerable, not to mention other false intervals that must necessarily arise from such a supposition.

Supposing then one tone increased, and the others diminished by half a comma, we should have our thirds major remain perfect. But still it would be necessary to examine what fifths this supposition would give. Now it is evident that a tone major added to an octave, makes just too fifths, thus $\frac{2}{1} \times \frac{9}{8} = \frac{9}{4} = \frac{3}{2} \times \frac{3}{2}$. But the tone here added is a tone major, and the tone we have assumed is a temperate tone, deficient from the tone major by half a comma; hence the sum of the two fifths, on this supposition, will fall short of the truth by $\frac{1}{2}$ of a comma, and consequently one fifth will be deficient by $\frac{1}{4}$ of a comma. Which difference, although it be sensible, yet experience shews, that fifths so diminished are tolerable.

This *Temperature* is what is called the common or vulgar *Temperature*, and consists, as has been said, in diminishing the fifth by $\frac{1}{4}$ of a comma, in preserving the third major perfect, and dividing it into two equal tones. Which being supposed, it follows that the fourth must exceed the truth by $\frac{1}{4}$ of a comma;

ma; that the third minor will be deficient by the fame quantity; that the fixth minor will be perfect, and the fixth major redundant by $\frac{1}{4}$ of a comma; and laftly, that the femitone major will exceed the truth by $\frac{1}{4}$ of a comma. If we introduce chromatic notes, or flats and fharps, the femitone minor will alfo exceed the truth by $\frac{1}{4}$ of a comma, and confequently the difference between the two femitones, or the diefis enharmonica, will be preferved.

If then we had a harpfichord or organ, with each feint or half note divided, we fhould have the following notes or founds, *viz.* C . C♯ . D^b . D . D♯ . E^b . E . F . F♯ . G^b . G . G♯ . A^b . A . A♯ . B^b . B . c. in the compafs of an octave. Yet this fyftem of notes, numerous as they feem, would not be fufficient for all tranfitions and tranfpofitions. For tho' a piece of mufic, tranfpofed to any of the natural keys C . D . E . F . G . A . B. and to the flats, as E^b and B^b, and fome others, would do well; yet in tranfpofing to fharps, as to C♯. we fhould not find a true third major, unlefs we introduced E♯. and even in flats, as A^b and E^b we fhould not find a true third major in defcending, or a fixth minor in afcending, unlefs we introduced F^b and C^b. and in like manner tranfpofitions to G♯ and E^b would oblige us to introduce B♯ and C^b. Nor would even this fuffice; for if neceffity required a tranfpofition from the key of C to that of D♯, we fhould not find a true third major without introducing F♯♯ and *c*. So that at laft we fhould come to a temperate fyftem, where, in afcending, the notes C, D, F, G, A would each have its fharp and double fharp, and the notes B and E each a fingle fharp. In defcending, the notes E, D, B, A, G would each have their flat and double flat, and the notes F and C each a fingle flat. And thus the octave would be divided into 31 intervals, whofe defignations are C . D^{bb} . C♯ . D^b .

1 . 2 . 3 . 4

C♯♯ . D . E^{bb} . D♯ . E^b . D♯♯ . E . F^b . E♯ . F . G^{bb} . F♯ .

5 . 6 . 7 . 8 9 . 10 . 11 . 12 . 13 . 14 . 15 . 16

G^b . F♯♯ . G . A^{bb} . G♯ . A^b . G♯♯ . A . B^{bb} . A♯ . B^b

17 . 18 . 19 . 20 . 21 . 22 . 23 . 24 . 25 . 26 .

. A♯♯ . B . C^b . B♯ . C. Where the letters C . D . E .

27 . 28 . 29 . 30 . 31.

F . G . A . B. fignify the common diatonic notes; thofe marked with a fingle ♯ or b are the chromatic, and thofe marked with a double ♯♯ or bb are enharmonic notes; fo called, becaufe the interval between them and the next diatonic note is an enharmonic diefis; for which reafon the notes E♯ . F^b. and B♯ . C^b. are alfo enharmonic.

But even in this divifion of the octave, all the notes would not have a third major in afcending and defcending; thus, for inftance, D♯♯ has no third major; for this would be F♯♯♯, which is not in the fcale, nor can any number of additional notes fuffice in all cafes. But this inconvenience is eafily remedied, and the fyftem confiderably improved by making all the 31 intervals equal. We have already obferved, that in the common temperature the femitones major and minor exceed the truth by $\frac{1}{4}$ of a comma, and that the enharmonic diefis is preferved true. Hence it follows, that the hyperoche, or difference between the chromatic and enharmonic diefis; for example, the interval between F^b and E♯ or D^{bb} and C♯, *&c.* will alfo exceed the truth by $\frac{1}{4}$ comma. Now the hyperoche, by our table, under INTERVAL, is equal to 1 . 37695, to which adding $\frac{1}{4}$ comma = 0 . 25000, we have 1 . 62695, which differs from the enharmonic diefis 1 . 90917 only by 0 . 28222, or about $\frac{2}{7}$ of a comma. Neglecting this fmall difference, let us fuppofe all the 31 intervals of the octave equal, it will follow that tranfpofitions to all the notes of the fyftem, whether diatonic, chromatic or enharmonic, will be equally good, and differ only in pitch or tone, as they ought, but not in accuracy, which muft next be examined.

The divifion of the octave into 31 parts may be conveniently done by logarithms. Under the head INTERVAL I find the logarithm of the octave = 55 . 79763 commas, confequently each diefis, or divifion of the octave = 1 . 79992 commas; hence the fifth, being 18 diefis, will be 32 . 399 commas. Now the true fifth is 32 . 640, the fifth confequently in this *Temperature* is deficient by 0 . 241 parts of a comma, which is lefs than $\frac{1}{4}$ of a comma by $\frac{1}{110}$ part; and therefore this fifth will, ftrictly fpeaking, be better than that of the vulgar *Temperature* by $\frac{1}{110}$ of a comma; but this is infenfible. Next, proceeding to examine the third, we fhall find it equal to 10 diefis or divifions, that is 17 . 999 commas, and the true third major being 17 . 963 commas, the difference is 0 . 036, that is about $\frac{1}{28}$ of a comma. Now as the ear can bear a fifth, altered by $\frac{1}{4}$ of a comma, it will much more eafily bear the alteration of $\frac{1}{28}$ of a comma in a third major. Again, in this *Temperature*, the third minor is indeed, ftrictly fpeaking, worfe than in the vulgar, which differs from the truth but by $\frac{1}{4}$ comma, whereas here it differs by about $\frac{1}{17}$ of a comma more; but then this difference is infenfible.

Thus we have been led from the confideration of the vulgar *Temperature*, to the invention of the *Temperature* which divides the octave into 31 equal intervals, commonly called, *Huygens's Temperature*. This great mathematician was indeed the firft who gave a diftinct account of it, and fhewed its ufe and accuracy. But here, as in many other inventions, we find the hint of the thing much older than the true knowledge of it. See *Hugenii* Opera Omnia, vol. 1. p. 748, 749. Edit. 1. Lugd. Batav. 1724.

The divifion of the octave into 31 parts, was invented in Italy about 200 years ago, by Don Nicola Vincentino. The title of his book is *L'Antica Mufica ridotta alla moderna prattica*, &c. Roma, 1555. Fol. and an inftrument called *archicembalo* was made upon this fcheme, as Salinas informs us, who at the fame time condemns it as very difagreeable in practice. But this could be owing to nothing but its not being tuned according to the intention of the inventor. For if all the thirds major of this inftrument were made perfect, and the fifths diminifhed by $\frac{1}{4}$ of a comma, it is evident that the inftrument would be equally exact with any tuned according to the vulgar *Temperature*, and would fuffice for tranfpofitions to any diatonic or chromatic notes, though not to all the enharmonic, as D♯♯, *&c.* becaufe we fhould not find its third major. And if the inftrument were tuned according to Mr. Huygens's fcheme, of making all the divifions equal, it would then have all the 31 keys equally good, and very near the truth. See *Salinas*, lib. 3. The title of his work is *Francifci Salinæ Burgenfis de Mufica Libri Septem, Salmanticæ*, 1577. Folio. *Merfennus*'s Work is entitled *Harmonicorum*, Libri XII. *authore* F. M. Merfenuo *Minimo, Lutetiæ Parifiorum*, 1648. Fol. He publifhed another book before this, the title of which is, *Harmonie Univerfelle, contenant la Theorie & la Pratique de la Mufique. Paris*, 1636. Fol. 2 vol.

Hence it is plain, Salinas and Merfennus had not fufficiently examined this matter.

The ufe of this *Temperature* of Mr. Huygens deferves to be introduced into the practice of mufic, as it will facilitate the execution of all the genera of mufic, whether diatonic, chromatic, or enharmonic; nor does the multiplicity of its parts render it impracticable, the author affuring us, that he had harpfichord made at Paris with fuch divifions, which was approved of, and imitated by fome able muficians. Merfennus alfo gives a fcheme for this purpofe; and Salinas fays, he faw and played upon fuch an inftrument. See alfo Don *Vincentino* before cited, lib. 5. p. 99, *&c.*

Mr. Huygens, to facilitate the tuning of inftruments with fuch divifions, has given us a table of the parts of an octave, according to his fyftem, together with their logarithms. The table is as follows:

The divifion of the octave into 31 equal parts.					The divifion of the octave according to the common *Temperament*.

4,9999999993	100000	Ut	C	100000	5,0000000000

The fecond column of this table contains the numbers expreffing the lengths of chords making 31 equal divifions, the longeft anfwering to C, being fuppofed to be divided into 100,000 parts.

In the third column are the fyllables by which the notes are ufually named in France; and the afterifc * fhews fome enharmonic notes, of which that near *Sol* is moft neceffary.

In the fourth column are the letters commonly ufed to denote the founds of the octave.

The numbers of the fecond column were found by means of thofe in the firft, which are their refpective logarithms; and thefe were found by dividing 0.30102999566 the logarithm of

of 2 by 31. The quotient 97106450 is marked N. and being continually added to the logarithm of 50000 that is to 4.6989700043 gives all the logarithms of the first column to the greatest 4.9999999993, which being extremely near to 5.0000000000 the logarithm of 100000, shews the operation to have been rightly performed.

The fifth column shews the lengths of the chords in the common *Temperament*: And the sixth column contains their respective logarithms. V. *Huygenii* Opera, vol. 1. p. 752, 753. The learned author of this *Temperature* has not given the notes answering to all the divisions of the octave; but that may easily be supplied from what has been said above, when we derived this *Temperature*, from the consideration of the common.

We have already mentioned the advantages of Mr. Huygens's system; but its excellency will better appear by comparing it with the schemes of others. We may distinguish and name the different *Temperatures* by the number of equal parts, into which the octave is supposed to be divided. The *Temperatures* that occur in books, are *Temperatures* of 12, 19, 31, 43, 50, 53 and 55 parts, of which in order.

The *Temperature* of 12 parts is founded on the supposition that the semitones major and minor may be made equal. Hence the octave will be divided into 12 equal semitones, 7 of which will make the fifth, 4 the third, and 3 the third minor.

The *Temperature* of 19 parts goes upon the supposition that the semitone major is the double of the semitone minor. Hence the tone will be 3, and the third major 6. The diesis enharmonica will be 1, and consequently the octave being 3 thirds, and a diesis, will be 19. The fifth contains 11 parts. The harpsichord in this scheme will have every feint cut in two, one for the sharp of the lower note, and the other for the flat of the higher. Between B and C, and between E and F, will be interposed keys, which must serve for the sharps of B and E, and the flats of C and F respectively.

The *Temperature* of 31 parts is Mr. Huygens's already described; here the semitones are as 3 to 2. The third major is 10, and the fifth 18.

The *Temperature* of 43 is Mr. Sauveur's, and by him very fully described in the memoirs of the Royal Academy of Sciences, An. 1701, 1702. He supposes the proportion of the semitones to be as 4 to 3. Hence his tone is 7. The third major 14, the fifth is 25, and the octave 43. What musical foundation this learned gentleman went upon in the investigation of this *Temperature*, I know not: But it seems liable to insuperable difficulties; for here the diesis enharmonica is but the half of the difference between it and the chromatic diesis; whereas, in truth, this difference, instead of being double of, is really less than the enharmonic diesis, as was long ago objected to him by Mr. Hensling, and appears from the table under the head INTERVAL. Miscel. Berolin. Tom. 1. p. 285, 286.

Besides, his enharmonic diesis falls greatly short of the truth, being but 1.27 of a comma, which is an error of 0.64 or near $\frac{2}{3}$ of a comma. Whereas in Mr. Huygens's *Temperature*, the error of the diesis is almost insensible, being but $\frac{1}{10}$ of a comma. Nor are the practical advantages of Mr. Sauveur's system any way comparable to Huygen's. His fifth is indeed, strictly speaking, better; but so little, that the difference is not sensible, not being $\frac{1}{20}$ of a comma. On the other hand, his thirds are sensibly worse, the major being $\frac{1}{5}$ and the minor $\frac{2}{5}$ of a comma false. Whereas Huygens's third major does not differ sensibly from the truth, and the minor has no sensible difference from the third minor deficient by $\frac{1}{4}$ comma of the common *Temperature*, which ought to be deemed the limit of the diminution of concords. If we add to this, that the much greater number of parts in Mr. Sauveur's octave, makes it vastly more intricate than Mr. Huygens's, and that these parts would be false or useless, even supposing the enharmonic genus restored, I believe no musician will long hesitate which he ought to prefer.

The *Temperature* of 50 parts is proposed by Mr. Hensling in the Miscellan. Berolin. above cited; he takes the proportion of the semitones as 5 to 3; hence his tone is 8, the third major 16, the fifth 29, and the octave 50. The third major and fifth in this system will be worse than Huygens's, though the third minor be a little better. The third major is here less than the true, and the fifth deficient by more than $\frac{1}{4}$ comma, which is a fault, not to mention the inconveniency arising from dividing the octave into 50 parts; besides 5 : 3 the proportion of the semitones here assumed, although expressed in greater numbers, is not so near the truth as Mr. Huygens's of 3 : 2. We have given the proof of this under the head RATIO.

The *Temperature* of 53 parts is mentioned by Mersennus. Here the tones will be unequal, 9 being the tone major, and 8 the minor. Hence the third major will be 17, and the fifth 31, which last does not differ from the truth by above $\frac{1}{333}$ part of a comma. The third minor is also more perfect than in Mr. Huygen's system: But the multiplicity of parts in the octave of this system, render it too intricate; and the distinction of tones major and minor upon fixed instruments, is, I doubt, impracticable.

The last *Temperature* we have mentioned is that of 55 parts, which Mr. Sauveur calls the *Temperature* of practical musicians. Its foundation lies in assuming the proportion of the semi-tones, as 5 to 4, so the tone will be 9, the third 18, and the fifth 32. The fifth in this system, as in that which makes the semitones equal, is nearer the truth than Mr. Huygens's, but this advantage is not $\frac{1}{15}$ of a comma; and on the other hand, the thirds both major and minor are here greatly mis-tuned, as will appear by the annexed Table, exhibiting the thirds and fifths of these several *Temperatures*, as also the thirds and fifths of the common *Temperature*, and two mentioned by Salinas, marked 1st. Salin. 2d. Salin. The letter V. stands for the fifth; III. for the third major, and 3. for the third minor. The fifths are all deficient, but the thirds are sometimes greater and sometimes less than the true; the first are marked +, the others —.

Temperatures formed by the division of the octave into equal parts, may be called geometrical *Temperatures*. The common and the two mentioned by Salinas, do not proceed upon this foundation. The intention of the first inventors not having been to make transpositions to every note of the system equally good; but only to make the most usual transitions in the course of a piece of music tolerable. Hence the parts of the octave, in their suppositions, were not all equal.

The common *Temperature*, as we have said, preserves the third major perfect. The first of Salinas, preserves the third minor perfect. In the second of Salinas, the semitone minor is perfect. The foundation of his first *Temperature* is making the temperate tone equal to the tone-minor and $\frac{1}{3}$ of a comma, or to the tone-major less $\frac{2}{3}$ of a comma. Hence his fifth and third major will be deficient by $\frac{1}{3}$ of a comma; and the third minor consequently, will be true. The ground of his second scheme is, to add $\frac{3}{7}$ of a comma to the tone-minor, or take $\frac{4}{7}$ from the tone-major, for his temperate tone. Hence the fifth will be deficient by $\frac{2}{7}$ of a comma, and the thirds major and minor each deficient by $\frac{1}{7}$ of a comma. Consequently the semi-tone, being their difference, will be preserved.

As to Mr. Salmon's scale, in the Philosophical Transactions, there is nothing true in it, but the diatonic scale of C. His scale for A is false, the fourth being erroneous by a comma; most of his semi-tones are likewise false. In short, it can neither be considered as a true scale, nor as a *Temperature*.

Before we close this article, it may be proper to add a few words about the method of invention of the foregoing geometrical *Temperatures*. Mr. Huygens having had the hint of a division of the octave into 31 parts, had nothing farther to do but to examine it by logarithms. But, supposing no such hint had been given, he might have investigated it directly by the method laid down by himself, and also by Dr. Wallis, and Mr. Cotes, for approximating to the value of given ratio's, in smaller numbers. We have given Mr. Cotes's method, under the head RATIO. The application of that method to the present purpose, is thus: The ratio of the octave to the third major is 55.79763 to 17.96282, and the approximating ratios will be

1°. greater than the true 28 : 9, 87 : 28, &c.

2°. less than the true 3 : 1, 31 : 10, 59 : 19, 205 : 66, &c.

The ratios greater than the true, must all be rejected; because they give the third major less than true, and consequently the tone, (its half) deficient by above $\frac{1}{2}$ comma; which gives the fifth deficient above $\frac{1}{4}$ of a comma; but this ought not to be. The first of the ratios less than true, is 3 : 1, or 12 : 4, which is the *Temperature* of 12 parts before described, and too inaccurate. The next is 31 : 10, or Mr. Huygens's. The rest divide the octave into too many parts.

The

The fame may be alfo found thus; the ratio of the octave to the common temperate fifth, deficient by $\frac{1}{4}$ of a comma, is 55.79763 to 32.38952. The approximating ratios to which are,

1°. greater than the true 2 : 1, 7 : 4, 19 : 11, 50 : 29, &c.
2°. lefs than the true 1 : 1, 3 : 2, 5 : 3, 12 : 7, 31 : 18, 205 : 119. Where we have the *Temperatures* of, 12, 19, 31, and 50 parts, before examined.

And here all ratios greater than the true, ought to be rejected; becaufe they give the fifth lefs than true, that is, in this cafe deficient by more than $\frac{1}{4}$ of a comma.

If we inveftigate the approximating ratios to the ratio of the femi-tones major and minor, or 5.19529 to 3.28612, we fhall have the ratios 1 : 1, 2 : 1, 3 : 2, 5 : 3, which refpectively give the *Temperatures* of 12, 19, 31 and 50 parts, before defcribed.

Again, inveftigating the approximating ratios of the fifth to the third major, we fhall find 7 : 4, 9 : 5, 11 : 6, 29 : 16, which will alfo give the *Temperatures* 12, 19, 31, 50, as before.

Laftly, the approximated ratios of the octave to the true fifth, are 12 : 7 and 53 : 31 greater than the true. The others being of no ufe, fince the fifth muft neceffarily be diminifhed. Here we find the *Temperature* of 53 parts. As to the *Temperatures* of 43 and 55, being deftitute of any mufical foundation, it is no wonder they do not appear by this method of inveftigation.

Mr. Huygens, in his Cofmotheoros, fays, that the tone or pitch of the voice cannot be preferved, unlefs the confonants be tempered, fo as to deviate a little from the higheft perfection. For the proof of this affertion, he brings a melody confifting of the following founds, C, F, D, G, C; where, if the intervals were to be fung perfect, by taking the interval from C to F a true fourth afcending, from F to D a third minor defcending, from D to G a true fourth afcending, and laftly, from G to C a true fifth defcending; we fhould fall a comma below the C from whence we began. Therefore, if we were to repeat this feries of notes nine times, we fhould at laft fall near a tone major below our firft found.

Mr. Huygens's folution of this difficulty is, that we remember the note from whence we fet out, and return to it by a fecret *Temperature*, thereby finging the intervals a little imperfect; which, he fays, will be found neceffary in almoft all fongs or melodies.

A like difficulty is mentioned in the Memoirs of the Royal Academy of Sciences; and is there urged for the neceffity of a *Temperature*, even for finging in the fame key. And Mr. Huygens's folution of the difficulty is there approved of. An. 1707. p. 264.

But the folution of thefe learned gentlemen is, as yet, far from being decifive. No experiment has yet been brought to fhew that the human voice fings tempered notes; not even when accompanied by tempered inftruments. It feems to us, on the contrary, that an exercifed voice guided by a good ear, fings true, even though accompanied by a mif-tuned inftrument, as harpfichords moft frequently are, efpecially in tranfpofed keys. And were thefe inftruments always as well tuned as art could make them, yet their tones would be equal; and it feems evident to the ear, that the human voice finging naturally two tones in fucceffion, as C, D, E, never makes them equal; and cannot, without great difficulty, and by means of a variation of harmony, be brought to make them equal.

Another folution, therefore, of Mr. Huygens's difficulty, muft be fought for. The truth feems to be, that the fecond of the key muft be the true tone-major above the key, and therefore the third between the fecond and fourth of the key muft be fung deficient by a comma. Thus in the key of C, from C to D will be a tone-major $= \frac{9}{8}$, and from D to F will be a deficient third $= \frac{32}{27}$. See the article INTERVAL.

Mr. Huygens's melody therefore, will ftand thus:

C, F, D, G, C.

$\frac{4}{3} \times \frac{27}{32} \times \frac{4}{3} \times \frac{2}{3} = 1$. And the voice would fing the interval F, D, juft as if the note E had been interpofed; in which cafe the notes would be C, F, E, D, G, C.

$$\frac{4}{3} \times \frac{15}{16} \times \frac{9}{10} \times \frac{4}{3} \times \frac{2}{3} = 1.$$

Thefe notes all come within the diatonic fcale of C; and the voice naturally falls upon the note from whence it fet out. The fame anfwer will hold in the example, mentioned in the Memoirs of the Academy of Sciences; where the intervals ♭B, G, E, C, occur. And here the interval from ♭B to G fhould be taken $= \frac{27}{32} = \frac{15}{16} \times \frac{9}{10}$, as in the former example; and for the fame reafon, the key being F.

There feems therefore no repugnancy between the practice and theory of mufic, while the melody is confined to one key; but it muft be owned, that in tranfitions from key to key, efpecially where feveral parts are to make harmony with each other, there ftill remain difficulties, not mentioned by Mr. Huygens, or any other writer we know of, which might deferve a farther examination.

We muft not omit mentioning, that the learned Dr. Smith, in his Harmonics, has not only carried the theory of *Temperaments*, or *Temperatures*, far beyond all the authors that preceded him; but has fhewn how to tune an inftrument, according to any propofed *Temperament*, by the ear only, which is certainly a moft ingenious difcovery.

This learned author[a] prefers what he calls the *Temperament* of equal harmony, which differs infenfibly from the divifion of the octave into 50 parts, to all others; and infifts, that it labours under the feweft defects, and is of all others the moft agreeable in practice. In the fyftem of equal harmony the *Temperaments* of the fifth, third major and third minor, are refpectively, $\frac{5}{18}$ and $\frac{2}{18}$ and $\frac{3}{18}$ of a comma lefs than the truth[b]. It would be impoffible here to do juftice to the learned author's reafonings on this fubject; we fhall only add, that he eftablifhes, contrary to the common opinion, that the lefs fimple confonances, generally fpeaking, will not bear fo great *Temperaments* as the fimpler confonances[c].—[[a] *Smith*'s Harmonics, p. 172, 188. [b] Ibid. p. 172. [c] Ibid. p. 146.]

Dr. Smith mentions a *Temperament* communicated to him by the ingenious Mr. Harrifon, which confifts in making the proportion between the octave and third major equal to that of the circumference of a circle to its diameter. In this *Temperament* the third major is diminifhed by $\frac{1}{5}$ of a comma, but the third minor is very near the truth, and extremely beautiful. *Smith.* pref. p. xi

A late author[a] feems to think the divifion of the octave into 31 parts, not to be of modern invention, but neceffarily implied in the doctrine of the antients. At firft fight it would feem, as if the antients made but 24 diefis or divifions in the octave, *viz.* ten to each fourth, and four to the tone; which (the octave being equal to two fourths and a tone) gives twenty-four diefes to the octave. But the author juft quoted contends, that this divifion is to be underftood only in one tenfion, that is either afcending or defcending; but that accurately fpeaking, if we confider all the diefes or divifions of the fourth, both afcending and defcending, we fhall find thirteen; five to each tone, and three to the femi-tone major; and confequently thirty-one divifions in the octave. Thefe indeed are not all naturally equal; but if we make them fo, we fhall have a *Temperature* known by the moderns under the name of Huygens's *Temperature*[b].—[[a] Dr. *Pepufch*, in Phil. Tranf. N°. 481. p. 273. [b] Phil. Tranf. ibid.] See the article DIESIS.

TEMPERATURE, or CLIMATE for plants. The difference of *Climate*, or *Temperature* of the air has a very great effect on plants. The different degree of heat is the great caufe of thefe changes, and the different degree of moifture fomewhat affifts in it. The American and Afian plants, famous in medicine when of the growth of their native foils, yet when removed into our *Climate*, though they grow and even produce their flowers and ripen their feeds, which feems the laft perfection of a plant, when put to the trial, have been always found to want their proper medicinal virtues.

Many of thofe plants and trees, which though natives of another *Climate*, will endure the open air with us, and grow in our gardens; yet lofe much of their ftrength, and become dwarfs, in proportion to what they were when in their proper *Climate*. But much lefs violent changes than thefe are able to produce the like effects, at leaft in fome degree. The feveral parts of Europe are able to alter the quality of the fame plant, even while it grows naturally in them. Thus the blue aconite or napellus, the root of which is a terrible poifon in the fouth of France; yet in Britany, a northern province of the fame kingdom, the root of the fame plant, though it feems to grow with equal vigour there, and is equally large and fucculent, has no bad effects; but has been eaten by old people and by children, without any injury.

In general, the farther north we go the lefs and lefs hurtful this plant becomes. It is common to almoft all Europe, and we find the inhabitants of fome places dreading it, and that with great juftice, as a fatal poifon; while thofe of others eat the leaves in their fallads, and even efteem them good to reftore the appetite.

The common woad which fucceeds well in many parts of England, is not fo certain in France; but the different *Climates* in different parts of that great kingdom, make ftrange alterations in its juices. In Upper Languedoc they raife great quantities of it, and it makes an extremely fine blue dye for ftuffs of all kinds; but in Britany, though the plant grows as high, and feems to flourifh as well, yet the leaves never are fo fucculent, and the colour obtained from them is not of fo fine a blue, but is dufky and brownifh.

This effect of the different *Climates*, in changing the nature of things produced in them, is not confined to plants; but the animal kingdom fhares in it. The whole ferpent kind are in general larger and more venomous, as we approach the hotter *Climates*. The tarantula, fo poifonous in the hot countries, is found greatly lefs fo as it is found in more cold regions; and the fcorpion, whofe fting is fatal in fome parts of Africa, is little more mifchievous than the wafp or hornet in fome of the coldeft places where it lives. Nay, the Philofophical Tranfactions inform us, that the bite of the tarantula, even in thofe very places where moft mifchievous, does not exert its power in cold weather; but that a perfon bitten at fuch a time feels not the effect of the bite till the next fultry hot day, though that may not happen till after two or three weeks.

The differences made by variety of *Climates* upon plants, are not limited to diftance of place, but even in the fame province the *Climate* differs greatly in different years, by means of accidents, and more or lefs heat; and more or lefs moifture will do as much violence to plants fometimes, as change of place, which only operates by means of the fame agents. Our farmers complain of great mifchiefs, from long droughts; and the French hufbandmen, in many of the provinces, always find, that when there has fallen very much rain, or thick fogs have been very frequent, all the bread-corn of every kind degenerates; the wheat and barley are poor and thin in the ear, and the grain fmall; but the rye becomes fo altered, that it is pernicious to ufe it in making of bread; and the poor, who are obliged to eat the bread made with it, are fubjected to many difeafes by it. They call the rye thus vitiated *Ergot*, and *blé cornu*. *Defland's* Trait. Phyf.

TEMPERING *of Bricks*. See the article BRICK-*making*.

TEMPLE (*Cycl.*)—*Temples* were originally all open, and hence received their name. See Phil. Tranf. N°. 471. fect. 5. where we have an account of an antient *Temple* in Ireland of the fame fort as our famous Stonehenge.

The word *Templum*, in its primary fenfe among the old Romans, fignified nothing more than a place fet apart, and confecrated by the Augurs; whether inclofed, or open; in the city, or in the fields. *Middlet.* of Rom. Sen. p. 135.

TEMPLUM *Softrati*, the name of a kind of chirurgical bandage, defcribed by Galen. He alfo defcribes another under the name of *Templum parvum Apollonii Tyrii*.

TEMPO *di Gavotta*, in mufic. See the article *Tempo di* GAVOTTA.

TEMPORALIS, (*Cycl.*) a broad flat mufcle, refembling the quadrant of a circle, and occupying all the femi-circular or femi-oval plane of the lateral region of the cranium, the *Temporal* foffæ, and part of the zygomatic. Through all the circumference of this femi-circular plane, the pericranium is divided into two laminæ. The internal lamina, which is fometimes taken for a particular periofteum, covers immediately all the bony parts of this region; the external lamina feparated from the other, is fpread out like an aponeurotic, or ligamentary tent, by means of its adhefions to the external angular apophyfis of the *os frontis*, to the pofterior edge of the fuperior apophyfis of the *os malæ*, and to the upper edge of all the zygomatic arch all the way to the root of the maftoide apophyfis.

This mufcle is compofed of two planes of flefhy fibres fixed to the two fides of a tendinous plane, nearly of the fame breadth with them by which they are feparated; it being fpread quite through the mufcle, like a concealed middle tendon; and the body of the mufcle thus formed, is inclofed between the two aponeurotic or ligamentary laminæ in the following manner:

The internal flefhy plane is fixed by a broad radiated infertion to all the femicircular plane of the cranium by the intervention of the internal lamina of the periofteum. Thus it is fixed to the lateral and external part of the *os frontis*, and to its external angular apophyfis, to the lower part of the *os parietale* to the fquammous portion of the *os temporis*, to the great ala or temporal apophyfis of the fphenoidal bone by which the temporal foffa is formed, and a little to the backfide of the internal orbitary apophyfis of the *os malæ*, which forms part of the zygomatic foffa.

The external flefhy plane is fixed in the fame radiated manner to the infide of the external lamina of the pericranium, from the great femi-circular circumference, all the way to a fmall portion of this lamina, more or lefs femi-circular above its infertion in the zygomatic arch; here the flefhy fibres leave the external lamina, and the void fpace is commonly filled with fat. The middle tendinous plane continues to contract by degrees, and ends at length in a very confiderable tendon, the extremity of which, which is in a manner double, encloses the coronoide apophyfis of the lower jaw. There is another fmall plane, reckoned by fome to be a portion of this mufcle, but in reality is no other than the third portion of the mafleter. *Winflow's* Anat. p. 251.

When the *Temporal* mufcles are wounded, at the fame time that there is a contufion of the cranium, which is frequently the cafe, the patient will be attended with great diforders; not only as thefe mufcles are neceffary for the offices of dividing the food, and for forming of fpeech, but becaufe they are furnifhed with nerves, tendons and arteries, all very confiderable, which will partake of the injury. Where there is no violent fymptom attending wounds on the external parts of the head, they are eafily cured by the common method ufed to frefh wounds, and there will be no occafion for futures, for fticking plafters will always anfwer the purpofe; but the dreffings muft always be finifhed with all poffible expedition; the medicines muft be always applied warm, and the air kept in a moderate heat with hot coals.

If there be any great degree of hæmorrhage from the wounded veffels, dry lint, or the ftyptic powders are to be ufed, and the whole kept on by compreffes and a proper bandage; and after the hæmorrhage is ftopped, the wound muft be dreffed with *mel rofarum*, or fome digeftive medicines, till fufficiently detorged, and then with a vulnerary balfam, or dry lint till it is healed. *Heifter's* Surg. p. 83.

TEMPOREGIATO, in the Italian mufic, fometimes fignifies, that the muficians who accompany the voice, or the perfon who beats time, fhould prolong fome particular part thereof, to give the actor or finger room to exprefs the paffion he is to reprefent, or to introduce fome graces by way of ornament to the piece.

TEMPOREGIATO is alfo ufed in a different fenfe, for *à Tempo*, or *à tempo giufto*.

TEMPORUM *Offa*. Thefe are two in number, fituated in the lower and lateral part of the fkull; the figure of each is partly femi-circular, refembling the fcale of a fifh, partly like a fhapelefs rock ending in feveral points.

Each of them is divided into two portions, one fuperior termed fquammous, from its figure; the other inferior, called *apophyfis petrofa*, or the rocky apophyfis; but that more from its hardnefs, than from the irregularity of its figure. This portion is eafily feparable from the former in children; and fome marks of this divifion are ufually found ftill remaining in adults.

They are alfo divided into two fides, one external and convex, the other internal and concave. Their external eminences are, the maftoide apophyfis in the lower and pofterior part of the bone; the zygomatic apophyfis in the anterior part; the ftyloide apophyfis under the bone, which feems originally to have been an epiphyfis; the capfular apophyfis, in which the bony ftilet feems as it were to be fet; the articular eminence of the zygomatic apophyfis, the lambdoidal angle, and the lower fide of the apophyfis petrofa.

Its external cavities are, the articular one immediately behind the eminence, called by the fame name; and which, with that, ferves for the articulation of the lower jaw. The crack in the articular cavities; the maftoide notch, in which the digaftric mufcle is inferted; the opening of the external *meatus auditorius*; the anterior indented border of that opening; the ftylomaftoide, or anterior maftoide hole, which is the orifice of the paffage of the *portio dura* of the auditory nerve, called from its form the aqueduct; the orifice or inferior hole of the carotide canal in the apophyfis petrofa, which alters its direction upward and forward, and ends at the point of the rock near the *fella fphenoidalis*; a portion of the jugular foffa, and a portion of the *foramen lacerum*.

Among the external cavities we are likewife to reckon a portion of the *ductus palatinus* of the ear, commonly called the Euftachian tube, and by fome the aqueduct; but by no means to be confounded with the other aqueduct, or ftylomaftoide; the zygomatic notch; the parietal notch; the fpheroidal notch; one or more little tubes, which receive the ramifications of the temporal artery; the groove in the apophyfis petrofa; by which it is connected to the great apophyfis of the *os occipitis*; the pofterior maftoide hole; but this hole is fometimes formed between this bone and the *os occipitis*, and is fometimes entirely wanting in one of the bones, and fometimes in both; and there is befide thefe, in fome fubjects, a fmall maftoide hole, which lofes itfelf in the fubftance of the bone.

In examining the internal eminences and cavities, we muft diftinguifh the fquammous portion from the apophyfis petrofa. In the former we fee the radiated indentations of the femicircular edge, which with the parietal bone forms the fquammous future; a portion of the middle foffa of the bafis cranii on the fame fide, and feveral inequalities on the fame fide.

The apophyfis petrofa, or rock, is a fort of pyramidal body, with three fides fituated obliquely, fo that its bafis is turned backward and outward, and its apex forward and inward toward the *fella turcica*: Of the three fides, one is fuperior and inclined a little forwards, the fecond pofterior, and the third inferior: This laft belongs to the outfide of the whole bone. The upper fide affifts in forming the middle foffa of the bafis cranii; and we obferve here a fmall irregular hole appearing to be double, and partly covered by a fmall bony plate; this is a kind of break or interruption in the duct, through which the *portio dura* of the auditory nerve paffes

In the back fide of the rock we fee the internal auditory hole, and a portion of the foffa for the cerebellum: fmall, indeterminate, and pretty deep depreffions are fometimes feen in it in children; but thefe are gradually obliterated as they grow up. At the bafis of this apophyfis we fee a portion of a groove in the lateral finus, formed partly in this bafis, partly in the lambdoidal angle; as alfo a portion of the *foramen lacerum*, and a fmall point which as it were divides this hole in two, and diftinguifhes the paffage of the jugular vein, from that of the eighth pair of nerves.

As this apophyfis has three fides, three angles are to be obferved in it; the firft fuperior between the upper and back fides, the fecond pofterior between the back and lower fides, and the third anterior between the lower and fore fide. The fuperior angle, which is the moft apparent, has a groove for the fmall finus of the *dura mater*. The pofterior angle is in a manner interrupted near the middle by the *foramen lacerum*, and from it proceeds the little bony point, which divides this hole; at the end of it is a grove by which it is connected with the

the great apophysis of the *os occipitis*. Between the apex of the apophysis petrosa, and the superior opening of the carotid canal, we sometimes meet with a small bone also of the sesamoide kind, mentioned long since by Riolan. Almost the whole substance of the *ossa temporum* is compact; the squamous portion is thin and transparent; the mastoide apophysis is hollowed by considerable cells; the apophysis petrosa is very hard and solid, with several internal cavities for the organ of hearing contained in it. *Winslow*'s Anatomy, p. 30. See the article TEMPORIS *Os*, *Cycl.*

TENACIOUS *Bodies*. See the article TENACITY.

TENACITY, in natural philosophy, that quality of bodies by which they sustain a considerable pressure or force without breaking. Mem. Acad. Berlin. 1745. p. 47.

Tenacity is the opposite quality to fragility or brittleness. See the article BRITTLENESS.

Tenacious bodies support the effort of percussion, or pressure, without receiving any damage: But here, and in many other cases, as when we use the words *hard*, *soft*, *flexible*, &c. we must be understood in a sense relative to the ordinary degrees of human strength; otherwise it would be difficult to say, what is *tenacious*, brittle, hard, soft, *&c.* Ibid.

TENCH, the English name of the *tinca* of the modern authors, the *fullo* and *gnapheus* of the antients.

It is, according to the Artedian system, a species of the cyprinus, and is distinguished by that author by the name of the blackish, mucous, or slimy cyprinus, with the end of the tail even. See the articles TINCA and CYPRINUS.

This is a delicately tasted fish, though it lives in foul water, and seems to feed very coarsely. It is always found in the muddiest parts of ponds, and where there are most weeds.

The slime of the skin of this fish is said to be of a healing nature, and to cure all fresh wounds; and it is pretended that the other fish know this property in it, and always apply to the *Tench* when wounded. Whether their opinion be true or false, the *Tench* has obtained by it the name of the *fishes physician*. The pike is said to pay such respect to this fish, on this account, that he never seizes him. But these are things easier to be fancied and said than proved; and if it should prove that the pike does not eat the *Tench*, it may be resolved into a much more natural cause, by supposing the slime of the *Tench* too disagreeable in his stomach to suffer it.

The season for angling for *Tench* is in June, July, and August. The time of their biting is early in the morning, or late in the evening, and in hot weather, all night long. The favourite bait for the *Tench* is a large red worm, and they will take this much more greedily if it be dipped in tar, after it is put on the hook. There are several sorts of paste also that he bites very well at, particularly one made of brown bread and honey, with an admixture of tar. All pastes that have any of the strong-scented oils in them, are also good baits. Other baits are the cad-worm, lob-worm, flag-worm, green gentle, marsh-worm, or soft boiled bread corn. All these will do very well at a proper season.

When a number of *Tench* are to be taken out of a muddy pond, where they will not bite freely at the hook, the method is to take a very good and large casting-net, well leaded, and with the meshes from the crown to a full yard and half, not too small, for then, if the pond be deep, the fish will strike away before the net gets to the bottom. The place where the net is intended to be thrown, must be made clean from bushes and large weeds, with a rake. When the place is thus cleared of any obstacles to the even descent of the net, a bait is to be prepared to draw the fish together, where the net is to be thrown. This bait is to be thus made: Put a quarter of a peck of wheat into three quarts of water, send it to an oven, and let it be well soaked, then add to it five pints of blood, and as much bran as is necessary to give it the consistence of a paste. Mix some clay with it, that it may the better hold together; and finally add a quart of lobworms chopped to pieces. Let the whole be wrought up into a stiff paste, and rolled into balls of the size of a hen's egg; and let these be thrown into the pond, in the place where the net is to be thrown. At times these, and at times some grains are to be thrown in; and the place in this manner thoroughly baited for several days. When the fish may be supposed to be very well acquainted with the spot, let a very good baiting be given in the morning, and in the close of the evening let the casting-net be carefully thrown in. When the net is sunk, the mud all about is to be stirred up with a long pole, with a fork at the end; the net is to lie half an hour, and the mud to be thus stirred all the time; by this means the *Tench* will be raised, and will be taken in the pulling out the net; but if the net were to be thrown in and taken out in the common way, there would hardly be one fish taken; for the custom of both *Tench* and carp, when they are frighted, is to plunge their heads up to the eyes in the mud, and thus placed, with their tails erect, any net in the world must draw over them, without a possibility of its entangling them.

TEND, in our old writers, seems to signify as much as *Tender* or offer; as to *tend* a traverse, an averment, *&c.* Briton, c. 76. Staundf. Prærog. 16. *Blount*, *Cowel.*

TENDO *Achillis*, in anatomy, is sometimes more peculiarly denominated *Chorda Achillis*, and *Chorda Magna*, or the great *Tendon*.

'Tis on the distance of the *Chorda Achillis* from the point of support, that the strength of the foot depends. The further this tendon is from the articulation, the stronger the part is found. Hence it is observed, that animals which run, or leap with the greatest ease, are those in which this *Tendon* is farthest removed. And men with long heels are better able to walk than others; and still the longer the foot, the more necessary is the length of heel. Petit. in Mem. de l'Acad. R. des Scienc. 1722. p. 75.

Anatomists are divided about the rupture of the *Tendon* of Achillis. Some hold this *Tendon* impossible to be broken by any effort whatever, and in proof hereof alledge its situation, which seems to secure it from such an accident. Others insist, that considering the great force which draws this *Tendon* downward, when in a leap or fall, the whole weight of the body bears on the top of the foot, or on the heel; 'tis easy to conceive, that a single effort may break it. Accordingly Pareus affirms, he has known it broken, on a slight occasion; as by a false step, a slip in mounting on horseback; and this without any visible injury, or solution of continuity of the part.

M. Petit, the surgeon, produces two other instances of his own knowledge: The first, of a posture-master named Clochoix, who, at the fair of S. Germains, endeavouring to jump, with his feet close together, upon a table 3 foot high, broke both the *Tendons of Achillis*, yet without any external wound [a]: The second, of a woman who broke the *Tendon of Achillis* of the right foot, by a fall in a boat, from a bench 6 foot high [b].—[[a] Mem. de l'Acad. R. des Scienc. 1722. p. 68. seq. [b] Traite des Malad. des Os. Jour des Scav. T. 74. p. 328.]

The phænomena ensuing on the rupture of the *Chorda Achillis*, in the first instance, were, that the patient could still contract or stretch his feet; that he could not stand upright; and that he felt no pain, either at the time of the rupture, or during the cure.

Notwithstanding this, several persons persist in the belief of the thing's being impossible; and contest both these instances, as not real ruptures of the *Tendon of Achillis*. A warm dispute has ensued between the author and Mr. Andry, and others, the particulars whereof are related by the Paris journalists. V. Jour. des Scav. T. 74. p. 328. seq. Id. T. 75. p. 483. seq. Id. T. 78, p. 230.—

Mr. *Petit* observes, that the *Tendons* are a sort of cords, which at one end part from a muscle, and at the other are joined to a bone, so that when the muscle contracts itself in its action, the *Tendon* draws toward it the bone to which it is infixed, and makes it perform such motions as it is capable of. The *Tendons* are substances not capable of extension; so that when a muscle acts, if the bone which it should, by that action, draw to a certain place, does not follow, either the bone must break, or the *Tendon* must be torn asunder; provided that the action of the muscle be of a proper strength.

We are next to consider, that in certain motions, such as that of the dancer, who is going to rise up from the ground, all the weight of his body is sustained by, and even overpowered by a certain number of muscles, which, having been thrown into a strong contraction, violently expand themselves again in a moment, and by that means cause the leap. If at the instant, when these muscles have stretched their *Tendons* to the utmost violence, there happens some accident by which these *Tendons* are again pulled downward by the whole weight of the body, it cannot be wondered at, that, strong as they are, they cannot resist so violent a force; and it was in this very manner that the dancer, cured by Mr. Petit, broke the *Tendons*. He was about to leap upon a table placed three foot above him; the *Tendon* could not but be extended to its full power in the attempt; and in trying, he sunk directly down again; by which means the weight of his whole body was added to the former force; and that force was yet increased by the acceleration of a fall from the height of three foot.

The *Tendo Achillis* is formed by an intimate union of the *Tendons* of two muscles; now if these two *Tendons* are both broken, the rupture of the *Tendon* is judged compleat; if one only is torn, and the other remains whole, the case is then called an imperfect or incompleat rupture of that *Tendon*.

There is a great difference between the compleat and the incompleat ruptures of this *Tendon*. The pain in the incompleat rupture is exceedingly great; whereas in the perfect one there is scarce any pain at all. When a *Tendon* is wholly divided, the two ends draw back different ways, like the string of a bow when cut, and this produces no pain, or any farther bad symptom, than the loss of the *Tendon*; which is so true, that, in order to take off the pain and other bad symptoms which attend the wounding, or imperfectly dividing a *Tendon*, the best means is to cut it wholly asunder.

The *Tendo Achillis* is placed in a sort of socket, where it plays freely every way, and has no connection or adherence with the adjacent parts; and hence a compleat rupture of it is without pain. This, however, is not the case, when only one of the two *Tendons* which compose it is divided, for then the separated ends of this retiring back as far as possible, cannot but violently affect the remaining entire *Tendon*, which with

them

them formed the *Tendo Achillis*; and as the union of these two is very strict, the pain succeeding the separation of one, and the retraction of its ends, cannot but be proportionably violent and great.

The pain felt in the division of one of these *Tendons*, or the imperfect rupture of the *Tendo Achillis*, is only perceived upwards or above the wound, not below it; the reason of which is, that the upper part of the divided *Tendon* is forcibly drawn up by the muscle by which it is contracted, while it is also drawn downward at the same time by the *Tendon* to which it is intimately and firmly united, and which yet remains whole; and this contrary force must produce the most exquisite pain in the fibres which resist; while the inferior portion, having no force applied to it but what tends to draw it downwards, easily yields to that, and is in no condition to suffer a like pain. This difference between the sensation of the two extremities is, however, only to be felt at first; since, after some time, the inflammation spreading, affects the neighbouring parts, and the lower extremity must feel its share; though even then the pain is much less acute in that portion than in the upper.

In case of a compleat rupture of this *Tendon*, the foot may be bent without causing any pain to the patient; the only effect is the encreasing the space which is between the divided ends of the *Tendon*: But the case is far otherwise in an imperfect rupture of this *Tendon*; the foot then cannot be bent without the utmost pain and agony, because the space between the divided ends of the *Tendon*, which must be enlarged by this bending, cannot be enlarged without a tearing, and violently forcing the imperfectly divided parts.

In the imperfect rupture of this *Tendon*, the patient may walk, though it is with very violent pain; but in the perfect rupture, the person cannot walk, though he suffers no pain at all. In walking, at every step that we take, the whole weight of the body is sustained by the hinder foot; now the *Tendo Achillis* is the only support, by means of which the foot can sustain that weight, or regulate its pressure; and therefore when that *Tendon* can no more perform its office, we can no more walk. These are the several symptoms by which the imperfect ruptures of this *Tendon* may be known from the compleat ones; a knowledge highly necessary to all who are to undertake their cure. Memoirs Acad. Par. 1728.

There have been instances of the *Tendo Achillis* having been cut through, and cured without stitching. See Commerc. Norimb. 1740. hebd. 46.

When a *Tendon* is wounded or divided, the part to which it belongs loses its motion; but if it is divided only in part, the symptoms it produces are much the same with those arising from a nerve wounded in the same manner. *Heister's* Surg. p. 28.

TENDON, in the manege, a sort of gristle that surrounds one part of a horse's foot, and is seated between the hoof and the coffin-bone, near the cronet. When a horse has a quitter-bone, the matter that gathers between the coffin-bone and the hoof, spoils the *Tendon*, and makes it black; and the cure of such a quitter-bone consists in cutting and extirpating the *Tendon*.

TENESMUS, (*Cycl.*) a name given by medical writers to a complaint, which is a continual desire of going to stool, but usually without any stool being ready to be voided. This is usually attended with some tumour, sometimes with a very considerable one in the part. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant.

Signs of it. These are a titillation and itching about the anus, attended with a violent burning pain, and a desire of compressing and voiding something, and this attended usually either with no excrement, or only a pulpous and mucous matter, and very often a procidentia ani, or falling down of the rectum.

Persons subject to it. This disease very often happens to people labouring under hæmorrhoidal disorders, especially when the discharges attending them do not succeed regularly, though nature gives all the necessary motions for their excretion. It happens also to people who are subject to void an acrid and bilious matter by stool, and not unfrequently to those who have a stone in the bladder. Women in the latter part of their time, in going with child, have also very often terrible fits of it, attended with considerable swelling; this happens to them from the pressure of the uterus, with its burden, upon the rectum and hæmorrhoidal veins. The procidentia ani happens also to all these subjects, and, beside these, is very familiar to infants, from their voiding an acrid matter by stool, and to all persons who are subject to great costiveness, and void their stools with great difficulty and pain; and finally, people who have paralytic weaknesses of the sphincter of the anus, incur this troublesome disorder after a time.

Causes of it. The causes of a *Tenesmus*, beside those already mentioned, of suppressions of the hæmorrhoidal discharges, and voiding acrid matter by stool, are the ascarides, a small sort of worms which usually infest the rectum, and occasion a continual iching and tickling there; the abuse of resinous purging medicines; and, among these, the resinous parts of aloes, and black hellebore, are, above all, most subject to remain in the rectum, and bring on this complaint: Much riding will also sometimes occasion it; and many people have been thrown into it by wiping their backside with paper in which pepper, ginger, or other hot and acrid things have been kept. The procidentia ani is owing usually to the same general causes, as also to the relaxation of the nervous and glandulous coat of the rectum, occasioned by long continued diarrhœas.

Prognostics in a TENESMUS. When a hiccough comes on upon a person in a *Tenesmus*, it is usually a bad omen; a violent *Tenesmus* coming upon women with child, sometimes occasions them to miscarry. In the mildest symptoms of the falling down of the anus, which is a frequent attendant on a *Tenesmus*, it is a very troublesome and painful disorder, especially when it continues some time, as it often does: And when there happens a tumour, and coldness in the part that is fallen, it very often becomes dangerous, threatening inflammation and mortification. In common cases, and where the distemperature has not before been frequent, the reducing the intestine to its place is usually an easy thing; but when there is any thing paralytic in the origin, it is more difficult both to restore it, and to prevent relapses.

Method of Cure. As the *Tenesmus* is merely a symptomatic disease, the primary disorder is to be examined, and treated, in order to a cure. Thus, when it is occasioned by ascarides, worm-medicines are to be given, and clysters of a proper kind injected, such as decoctions of tanzy, wormwood, and myrrh: When the worms are by this means destroyed, the *Tenesmus*, which was no more than a symptom, naturally ceases. In cases where it is caused by a flux of bilious matter by stool, or by a retention of the hæmorrhoidal discharges, it will be proper to give medicines to obtund the acrimony of the humours, and take off the spastic motions occasioned by them. To this purpose powders of nitre, crabs-eyes, and cinnabar, are to be given, and jellies of hartshorn, and the like, with gum-arabic, tragacanth, and such other agglutinants. The vapours of turpentine, and of the carminative seeds, received on the part, are also of great benefit; and hot fomentations of decoctions of the herbs of marshmallows and pellitory, and chamomile flowers. These ingredients may also be applied as a cataplasm; for beyond all things, external heat is of the most immediate service. The sitting over the steam of hot water is a very good thing, and the rubbing the part with an ointment made of mucilage of quince seeds, with oil of mullin, and the yolk of an egg. In cases where there is a procidentia ani, the gut is to be replaced as soon as possible; the person is, to this end, to be laid upon his belly, and a moderate force to be used in putting it back, the fingers being first rubbed over with oil of sweet almonds, before they touch the gut. If this is not to be done at the first attempts, the patient must be suffered to lie down again in a natural posture, and spunges, wetted with astringent decoctions, are to be applied to the part; powders of mastic, with a very small quantity of alum among it, also is useful to be sprinkled on the gut on this occasion. The sitting upon a bag of oatmeal, boiled to the consistence of pap, and sprinkled over with a small quantity of allum, is also a very good method. And so long as the intestine remains out of its place, it must be carefully kept warm, for fear of a mortification. If there is an inflammation attending it, this must be first carefully discussed by epithems of scordium, sage, chamomile, and rose and elder flowers; and, after this, the usual methods of attempting a reduction are to be employed. And finally, when the sphincter has a paralytic weakness, the ordinary methods are to be assisted by bandages, to prevent its return; but in a case of this kind, all that is to be done, is simply palliative, since the cure is not to be hoped. In cases where the *Tenesmus* is owing to bilious stools, or to the suppressions of the hæmorrhoidal discharges, the patients are carefully to abstain from all medicines in which aloes is an ingredient, as the elixir proprietatis, and the like.

In cases of the *Tenesmus* from the pressure of the womb in women with child, there is no cure but delivery; but the methods before proposed will palliate and give ease. When milk is given in clysters, in these cases there must be great care taken that it is perfectly fresh, not the least turned sour. If there be a colic attendant on the *Tenesmus*, provided that it be not a bilious one, it is always proper to inject clysters with a small quantity of common salt, to absterge the mucous humours; and when powders of the astringent kind are used, they must always be extremely fine, lest their particles, sticking to the inner coats of the intestine, should increase, instead of mitigating the disease. Alum must be added, but in very small quantities, to these powders, lest it astringe too violently, and by that means prevent instead of forwarding the reducing the part. Hartman commends the beetles found in horse-dung, dried and powdered, as a very powerful remedy in all cases of this kind. *Junk.* Consp. Med. p. 583. seq.

TENGA, in botany, a name by which some authors have called the coco-nut-tree, or *Palma Indica nucifera* of other writers. Hort. Malab. vol. 1. p. 1.

TENSION, (*Cycl.*) *Tensio*, Τάσις, in the antient music, was used to signify any pitch of sound, whether produced by intention or remission. Vid. *Aristoxen.* p. 10——13. Edit. Meibom.

Aristoxenus observes, there are five things to be considered about sounds, τασις, tention; ἐπίτασις, intention; ἄνεσις, remission; ὀξύτης, acumen; and βαρύτης, gravitas. Ibid. See these Terms in their proper Places.

TENSOR (*Cycl.*) — TENSOR *Tympani*, in anatomy, a name given by Albinus to one of the muscles of the ear, called by Cowper, *internus auris*, and by others, *internus mallei*.

TENT, (*Cycl.*) a small bundle of scraped lint, used in dressing some wounds, worked into the shape of a nail, with a broad flat head. They differ in thickness and length, according to the size of the wound for which they are intended.

They are chiefly used in deep wounds and ulcers, and are of service to convey medicines to the most inner recesses and sinuses of the wound. 2. To prevent the lips of the wound from uniting before it is healed at the bottom. And 3. By their assistance grumous blood, fordes, and other foulnesses, are readily evacuated.

They are to be made extremely soft, that the cure of the wound may not be retarded, by the pain they would otherwise bring on; but, that the wound may not be kept open too long, it is advisable, as soon as the part is sufficiently cleansed, and the sinuses are found to heal up, to lessen the sizes of the *Tents* by degrees, and as soon as safely and conveniently may be, to leave them entirely off.

Many surgeons, of great note, have entirely forbid the use of *Tents*, from the frequent observation of the ill effects arising from the surgeon's neglecting, or not knowing these necessary cautions.

There are, however, beside these *Tents* of scraped lint, another kind, made of linnen rags not scraped, worked up into a conical form, to the basis of which is fastened a strong thread; the apex of it must be a little unravelled, to make it softer, that it may not become painful. The thread is fastened to the basis, that it may be recovered with the greater ease, if by any accident it should be forced into the cavity of the thorax or abdomen, for these sort of *Tents* are chiefly used to keep open wounds that penetrate into the thorax or abdomen; in order to make way for the proper discharge of blood, matter, *&c.* by the mouth of the wounds.

A third sort of *Tents* there remains yet to be described, whose office is not only to keep open, but to enlarge, by degrees, the mouth of any wound, or ulcer, which shall be thought too strait, by which means a freer passage may be procured for the blood or matter that was confined; and that the proper medicines may find a more ready admittance.

These *Tents* are usually called *sponge Tents*, and are made either of sponge, or of the roots of gentian, calamus aromaticus, *&c.* for these kind of things imbibe the matter that flows to them, and being enlarged, by that means dilate the lips of the wound. *Heister*'s Surg. p. 17.

TENTHREDO, in natural history, the name of a fly of the stinging kind. It is of the size and shape of the bee, but of the colour of the wasp. It loves to be among meat, as in kitchens and larders; it is a very gregarious animal, but makes no honey, though whole swarms live together.

TENTORES, among the Romans, were persons appointed to hold the cloaths of the charioteers that contended in the circus. *Pitisc.* Lex. Antiq. in voc.

TENUIROSTRÆ, in zoology, the name of a genus of small birds, which feed on insects, and have slender and sharp beaks; of this genus are the lark, swallow, red breast, and a number of others. *Ray*'s Ornithology, p. 148.

TEPETOTOTL, in zoology, the name of a Brasilian bird, of the gallinaceous kind, more usually called *mituporanga*. See the article MITUPORANGA.

TEPHRIA, in the natural history of the antients, a name given to the grey ophites. See the article OPHITES.

TEPHROMANTIA, Τεφρομαντεία, in antiquity, a species of divination, performed with ashes; for which see *Potter*, Archæol. Græc. T. 1. p. 353.

TEPID, in natural history, a term used by writers on mineral waters, to express such of them as have a less sensible cold than common water.

They distinguish all the medicinal springs into three kinds; the hot, the *tepid*, and the cold; but the middle term might easily be misunderstood to mean a great deal more than they express by it; all that have what can be called the least sensible warmth, are called hot; and the *tepid* are distinguished from the absolutely cold, only by their being less cold.

Some of this class of mineral waters, and some few also of the cold ones, have a sharpish vinous taste, which is never observed in any of the hot ones. This taste is lost on the giving the waters the slightest heat, and is therefore very difficult to be guessed at as to its origin. It is not only found in the aluminous and vitriolate waters, but also in those which are manifestly nitrous, and which abound in sulphureous salts, quite different in their nature from acids. 'Tis therefore an additional somewhat, quite distinct from the saline properties of the fluid, and as easily connected with one kind of that as with the others.

The causes of heat in the mineral waters remains yet wholly unknown, notwithstanding all that has been written concerning it. It is hard to believe, that there are continual subterranean fires near enough the surface, to give a heat that preserves itself in so great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, sufficient in quantity and force to have given the same degree of heat to waters for so many ages, as some of our hot springs are known to have subsisted. *Duclos*'s Exam. des Eaux. Miner.

TEPIDARIUM, among the Romans, a *Tepid*, or blood-warm bath, which was joined to the cold and hot baths, and was a medium between the two; so that if any person wanted to go from the hot to the cold bath, or *vice versa*, he always took the *Tepid* bath in his way. *Pitisc.* in voc.

TERBEDH, in the materia medica, a name given by Avisenna to the *Turbith*, a purging-drug, mentioned by all the authors of his time; but in general, in a very confused manner.

The *Turbith* of Serapion is the *Tripolium* of the Greeks. The *Turbith* of other authors is the *pityusa* or the *alypum*-root; all these are things greatly differing from one another, and from the true *Turbith* of our shops described by Garcias.

The greatest critics have been perplexed what to determine as to the *Turbith* of Avisenna; it seems plainly different from all these; and though Scaliger, and others, make it also different from the *Turbith* of our times, and of Garcias; yet there is some reason to suspect that they err in this, and that the drug is the same.

This author says, that the *Turbith* of his time was a woody substance, brought from the East-Indies. This cannot belong to any of the other plants, as they are natives of Greece, not brought from the Indies, and as they were not woody, but herbaceous plants; but the *Turbith*, which we at this time receive from the Indies, is a woody stalk, and the virtues of it agree well with those ascribed by Avisenna to his *Turbith*.

Garcias tells us, that the Indians use it to purge phlegm, and that they add ginger to it by way of corrective; and Avisenna says the same thing, of its use in his time.

TERDINA, in the materia medica, a name by which Paracelsus, and some other authors, have called the great garden Valerian. *Ger. Emac.* Ind. 2.

TEREBINTHUS, the *Turpentine-tree*, in botany, the name of a genus of plants; the characters of which are these. The flower is of the apetalous kind, being composed of several stamina, furnished with their apices; these are however barren, and the embryo-fruits are produced on other plants of the same species, which produce no flowers. These finally become a capsule, composed of one or two cells, and containing oblong seeds. See Tab. 1. of Botany, Class 18.

To this it is to be added, that the leaves are pinnated, growing several over-against one another on a middle rib, which is terminated by an odd leaf.

The species of *Turpentine*, enumerated by Mr. Tournefort, are these: 1. The common *Turpentine*-tree. 2. The *Turpentine*-tree, with a larger eatable fruit, like the pistachia nut. 3. The *Turpentine*-tree, with small blue eatable fruit. 4. The Indian *Turpentine*-tree of Theophrastus, the pistachia of Dioscorides. 5. The trifoliate pistachia, or *Turpentine*-tree. 6. The *Turpentine*-tree of Cappadocia. 7. The American *Turpentine*-tree, with fruit like the pistachia, but not eatable. *Tourn.* Inst. p. 579.

TEREBOTIN, a word used by Paracelsus, for the common turpentine.

TEREBRA, (*Cycl.*) the name of a chirurgical instrument, used for the perforation of bones, or for the extracting of bullets, or other the like extraneous bodies, out of wounds.

TEREBRATULA, in natural history, a name given by Mr. Lhuyd to some species of the smooth conchæ anomiæ, which have near the head of the shell a small hole, which looks as if bored by art. See the article CONCHÆ *Anomiæ*.

TEREDO, a name given by naturalists, to a species of sea-worm, which eats its way into the bottoms of ships, lining the hole it makes with a kind of shelly matter.

The head of this creature is well prepared by nature for the hard offices it is to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech; by which it pierces wood, as that animal does the skin. A little above this it has two horns which seem a kind of continuation of the shell. The neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles. The rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and by means of the microscope, several other very remarkable particulars become visible there.

At that part where the intestines end, the tail begins; this is longer than all the rest of the body; it is depressed in the middle, and puffed out on each side, and is joined to the callous part of the lower end of the body, in an irregular manner, so that there is an indeterminate void space left between; this occupies the middle part between what the natural historians call two foleæ-form fins. This creature is wonderfully minute, when newly excluded from the egg, and at its utmost bigness is a foot long; three or four inches is however its more frequent length.

The skin of this little animal being stripped off, the heart, stomach, and intestines come plainly in view, as also the callous muscles of the neck, and two white ovaries; the heart is composed of two pyramidal vessels.

 The

The increafe of this pernicious infect is by eggs, and is fo very great, that Sellius, who has written a whole folio of its hiftory, computes there are in one parent more young at a time, than there are men in the eight largeft cities of Europe; fo that it is no wonder that fo many of thefe creatures are found in the bottom of a fhip, when they have once feized upon it; the only wonder is, that there are not many more. When the bottom of a veffel, or any other piece of wood conftantly under water, is inhabited and injured by ever fo great a number of thefe worms, there is no fign of the damage to be perceived on the furface, nor are the creatures vifible till the outer part of the wood is cut or broken away, then their fhelly habitations come in fight; thefe lie fo near the furface, however, as to have an eafy communication with the water, and there are a multitude of little perforations in the very furface through which the inhabitant infects throw out the extremities of their little fhelly horns. Thefe are of a reddifh colour, and may be diftinguifhed by an accurate obferver in form of fo many red prominent points; they all are retracted on the leaft touch, and are thrown out again as foon as all is quiet. From thefe points, or the fmall apertures which give them a way out, are the cells of the *Teredines* to be traced. They are compofed of a pearly or fhelly matter, which forms a long tube with various windings and turnings, which marks the abode of the creature; but which ufually neither adheres to the body of the animal, nor to the wood. Thefe cafes or tubes are always more or lefs loofe in the wood, and there is ever a large fpace within them, for the body of the animal to be furrounded every way with water. They are very fmooth on the inner furface, and fomewhat rougher without; and are much harder and firmer in the cells of the older and larger animals, than in thofe of the young ones.

Thefe fhelly tubes are compofed of feveral rings, or annular parts; but thefe differ greatly in their length.

There is an evident care in thefe creatures, as they are a republic, never to hurt or injure one another's habitations; and by this means each tubule or cafe is preferved entire, and in fuch pieces of wood as have been found eaten by them into a fort of honeycomb, there never is feen a paffage or communication between any two of the tubules, though the woody matter between them often is not thicker than a piece of writing-paper.

The creature depofits its eggs on the outfide of the bottom of a fhip, or any other piece of wood; the young worm hatched from this egg immediately eats its way into the wood, entering thus by a very minute hole, which is the reafon why the furface of wood ever fo much infefted with them fhews no fign of them; when they have made their way into the fubftance, they work forward in different directions, and when they find they approach one another, they turn fhort off, and direct their future courfe another way; and to this feems owing the twifted fhape of the tubules; neither are thefe every where of the fame dimenfions, but are always wider where the head and the foleæ-form fins are placed, than elfewhere; a free motion of both thefe parts being extremely neceffary to the well being of the animal.

The kind of wood in which thefe worms are lodged, makes a great difference in the appearance of their cells, as they work much more fpeedily and fuccefsfully in fome kinds, than in others. The fir and alder are the two kinds they feem to eat with the greateft eafe, and in which they grow to the greateft fize. In the oak they feem to make but a very flow progrefs, and ufually appear very fmall and poorly nourifhed. The colour of their fhelly tubules is often brown in this wood; which feems plainly owing to the effect of its juices.

Although the head of this creature feems extremely well formed for the eating into any fubftance, yet the hardnefs of oak, and of fome other fpecies of wood in which thefe animals are found, is fo great, that it feems fcarce credible that they could fairly have eat their way into it. Reaumur has proved that fome kinds of fhell-fifh have in part of their bodies a corrofive liquor; and many have fuppofed the *Teredo* to have fuch a liquor, and by that means to deftroy the wood. But there are many reafons againft this, as the exact and regular figure of the hole, the difficulty of corroding wood, *&c.* Sellius refolves the whole into the mere repeated action of water. He fuppofes the whole body of the *Teredo* to be an hydraulic engine, which, as it is always furrounded with fea-water in its cells, takes in and throws out part of this as it pleafes; and by continually difcharging water with fome violence againft that part of the wood into which it would make its way, it is fuppofed by degrees either wholly to wear it away, or at leaft to foften it in fuch a manner, as that it may be eafily gnawed away.

By this means alfo the tracheæ of the wood and other veffels, which in its growing ftate had ferved for its nutrition, are opened and enlarged, and make the way for wider holes much eafier than it would appear to any one who confidered the wood as one folid mafs.

When there comes an iron fpike, or other extraneous hard body in the way of one of thefe creatures in its courfe, it firft trys if it can eafily go round it, but if there appears any difficulty in that, it continues its battery of water againft it, and either by continued induftry makes its way through it, or perifhes in the attempt. The young ones when even but juft hatched from the egg, have this art of darting forth water, and by that means make their way, as well as by erofion into the wood.

One thing very remarkable is, that the body of the *Teredo* when grown to a moderate fize becomes the habitation at pleafure of a vaft multitude of fmall fea-water infects, which enter with the water into the cavity of the tubules, and are with it received into the body of the animal, and again thrown out againft the wood. In this, doubtlefs, many of them perifh; but millions at a time are alfo to be feen, living perfectly at eafe in the belly of the creature.

The vaft increafe of thefe animals, and their fhelly tubules, naturally leads to a confideration of the manner of their generation; and when we confider that each of thefe creatures is, from the time when it is produced from the egg, immediately lodged in a cell, in which it lives without the leaft poffibility of getting into that of another animal of its own kind, or receiving one of them into its own; it is not eafy to account for the propagation of the fpecies in the common way. This, however, is folved by an accurate anatomical obfervation of the animals themfelves; fince in every individual the parts of generation of both fexes, and both the femen and ovula are found. Each individual therefore evidently ferves by itfelf for the propagation of the fpecies; and this is probably very often the cafe in earthworms, and other of the hermaphrodite animals. All the yet known kinds of thefe being foft-bodied; and probably, though they often meet one another, and copulate in pairs, yet when they have not that opportunity, the parts copulate in the individual.

The eggs are found in great plenty in the bodies of thofe animals in June, and are after this difcharged with the water into the fea, where the far greater part of them, doubtlefs, become food for other fmall animals; and the few that come to good affix themfelves to any piece of wood they are wafhed againft, and there hatch and get into its fubftance in the manner of their parents.

Many other animals are great deftroyers of the eggs of the *Teredo* while they are fixed to the furface of the wood. The fcolopendræ marinæ eat them in great abundance; the fhrimps alfo, and the pulmo marinus devour them.

Poifonous ointments are alfo found to be of fome ufe in deftroying them, on rubbing over the wood; fome have thought that burning the furface was an effectual way of preferving them, but this has been found to be otherwife. The fureft method of avoiding them in particular works, is the ufing bitter or very folid woods; the firft kind they are found never to touch, and in the other they make but flow progrefs. Mixtures of lime, fulphur, and collocynth, with pitch, for covering over the furfaces of boards, *&c.* have been found of fome ufe.

It feems very evident, that boards and other pieces of wood have been fubject to be eaten by thefe animals, from all times that we have any knowledge of; for the ftone called *lapis fyringoides* is evidently no other than wood thus eaten, petrified by long lying in the earth, together with the tubules of the worms. The maffes of this with the grain of wood yet plain in them, are common in many places among fea-fhells, and other marine remains at great depths, and have evidently been brought thither in very diftant times, and before changes were made in the furface of the earth of which we have no accounts in our earlieft hiftories. *Sellii* Hift. Natur. Teredinis.

TERENJABIN, in the materia medica of the antient Arabians, a word ufed to exprefs a kind of manna called by fome *manna maftichina*, from its round globules refembling the drops of maftic, and by the phyficians of many parts of the world at prefent *manna perficum.* See the article MANNA *Perficum.*

Geoffroy indeed makes the *Terniabin*, or *Terenjabin* to be a kind of liquid manna; but this is an error into which he has been led by Bellonius, who, though a very cautious obferver in moft particulars, was evidently deceived in this, by the accounts of the monks of mount Sinai. Bellonius fays, that thefe monks collect a kind of liquid manna, which is called *Tereniabin*, and fold in the fhops at Cairo under that name; and adds, that this is the *mel rofcidum* of Galen, and *mel cedrinum* of Hippocrates; but it is very evident from the general confent of authors that this was not the fubftance called *Tereniabin* by the Arabians, and now *manna perficum.*

It feems indeed very probable, that this liquid manna collected by thefe monks, is the fame fubftance called *drofomeli*, and *aëromeli* by Galen, and *mel cedrinum* by Hippocrates (if there be no error in the text) though not the *Tereniabin.*

The defcription which Galen has left us of the *mel rofcidum*, and of the manner of collecting it on mount Sinai in his time, agrees very well with what Bellonius fays of it; and thefe circumftances feem to be agreed upon by all authors in regard to it, but it does not appear that its ufe as a medicine was known any thing near fo early as in the days of Hippocrates and Galen; the Arabian phyficians feeming to have been the firft who brought it into general ufe as a purge. Galen takes notice of the *mel rofcidum*, or liquid manna, more as

as a curiosity than as a medicine, no where mentioning its qualities as such, or saying any thing about its use. He says, that it was rarely met with in his country, but that it was gathered annually in considerable quantities on mount Sinai. And indeed from the manner in which it is spoken of by the old Greek writer cited by Athenæus, as mentioned by Salmasius, it should seem that it was only used for pleasure, as an agreeable sweet. What he says of it, being that it was sweeter and more agreeable to the taste than honey itself. Mesue tells us, that Galen mixed manna with scammony.

In the spurious piece *de dynamiis*, ascribed to Galen, scammony is indeed ordered to be mixed with honey, but he never once mentions manna in any of his writings on any such occasion. As Galen is known to be very minute and particular in his account of the materia medica at that time in use, his silence is a strong argument that even the mel roscidum was not in use as a medicine, much less any other species of manna. Phil. Transf. N°. 472. p. 90.

TERES (*Cycl.*)—TERES *Folium*, among botanists. See the article LEAF.

TERETRON, the name of a chirurgical instrument, more usually called *Terebra*.

TERFEZ, in natural history, the name given by the Africans to the truffles found in the desarts of Numidia, and other places in that part of the world in great abundance.

These are much more delicately tasted than the European truffles, and are white on the outside. They are called by some of the Africans *kema*, and by the Arabian writers *cantha*, and *camahe*.

TERM (*Cycl.*)—The use of *Terms* is necessary in order to render our abstractions clear and distinct, as also to retain them.

TERMOR, *Tenens ex termino*, in law, he that holds lands or tenements for a term of years, or life. *Litt.* 100. *Blount.*

TERNA, a word used by some authors, to express an impetigo. See the article IMPETIGO.

TERNA *Folia*, among botanists. See the article LEAF.

TERNARY *Number*, in antiquity, was esteemed a symbol of perfection, and held in great veneration among the antient mythologists. Whence Virgil,

——— *Numero Deus impare gaudet.* Ecl. 8. v. 75.

Servius on this place remarks, that the Pythagoræans ascribed the *Ternary* number to the supreme God, as being the beginning, middle, and end of all things. All the heathen gods had a threefold power attributed to them, as the *tria virginis ora Dianæ*, the three-forked thunderbolt of Jupiter, the trident of Neptune, the three-headed dog of Pluto. Again, the parcæ were three, the furies three, Hercules was three nights in begetting, the muses were antiently three, the graces three, &c. *Hofm.* Lex. univ. in voc.

This number was likewise used in most religious ceremonies, but especially in lustrations; whence Virgil, Æn. l. 11. v. 188.

Ter circum accensos, cincti fulgentibus armis
Decurrere rogos.————

TERPENTARIA, in botany, a name used by some authors for the *betonica aquatica*, or great water figwort, called waterbetony. *Ger. Emac.* Ind. 2.

TERRA, *Earth*, (*Cycl.*) in natural history, &c. see the article EARTH.

TERRA *de Baira*, in natural history, the name given by some to an earth of a white colour, found about Baira, not far from Palermo.

It is esteemed a very great medicine in the cure of malignant fevers, and in the stopping hæmorrhages of all kinds. The powder of it is commonly sold in Italy under the name of Claremont powder; a name it obtained from a person who first found out its virtues, and communicated them to the world in a treatise expresly written on the subject. *Boccone* Muf. de Fisic. See the article CLAREMONT *Powder*.

Chia TERRA, in the materia medica of the antients, an earth of the marle kind, found in the island of Chio, and given internally as an astringent; but its chief use among them was as a cosmetic, the ladies esteeming it the finest of all things for cleansing the skin, and defacing wrinkles.

What title it has to these qualities, the world has not of late ages inquired into; but the substance is still in being, and to be had in any quantities from the same place. And the descriptions Dioscorides and Galen have left us of it are so accurate, that there is not the least room to doubt but that the earth now found there was the very kind they used. It is a dense compacted earth, yet very soft and of a texture easily disunited and broken by water.

While in the stratum it is of a dusky greyish or bluish white, very dry, and of a shattery structure; when thrown upon the surface of the earth and left to the weather, it soon breaks into an impalpable powder, or melts into a substance like butter, and sinks into the earth again; but if taken up and dried, it becomes of a pale greyish white, and is seen to be laminated in its structure, or composed of a great number of plates or thin crusts. It is remarkably fine and soft to the touch; it adheres firmly to the tongue, is very easily broken and crumbled to pieces between the fingers, and a little stains the hands. Thrown into water it makes a slight bubbling and hissing noise, and afterwards swells and gradually melts into a substance like a thick cream. It ferments violently with acids, and suffers no change in a moderate fire, except that it becomes a little whiter; and by these characters may be distinguished from all the other white earths. *Hill*'s Hist. of Foss. p. 46.

TERRA *cimolia purpurascens*. See the article STEATITES.

TERRA *Foliata Tartari*. This saponaceous salt, which is a fixed alkali, saturated with distilled vinegar, is an excellent alterative and diuretic, when taken in the quantity of half a dram to two drams. If taken in the dose of three to six drams, it is a mild cathartic which never sinks the spirits, or occasions any violent disorder. It has been found of service in dropsies. Med. Eff. Edinb. abr. Vol. I. p. 166.

TERRA *Goltbergensis*. See the article GOLTBERGENSIS *Terra*.

TERRA *Hydata*, in our old writers, land subject to the payment of *Hydage*. *Selden. Blount.*

TERRA *Lignicensis*. See the article LIGNICENSIS *Terra*.

TERRA *Livonica*. See the article LIVONICA *Terra*.

TERRA *Melia*. See the article MELIA *Terra*.

TERRA *Melitensis*. See the article MELITENSIS *Terra*.

TERRA *Merita*, in the materia medica, a name given by some authors to the curcuma or turmeric root.

It is from a false pronunciation of this name *Terr merit*, that the English turmeric has its origin. *J. Baubin.* V. 2. p. 146.

Persica TERRA. See the article PERSICA *Terra*.

TERRA *Sigillata Magni Ducis*. See the article ETRUSCA *Terra*.

TERRA *Sigillata fusca*, a bole of a beautiful brown colour, found in Germany, England and America.

It is of a dense texture, makes no fermentation with the strongest acids, and if thrown into water, it soon separates into a number of thin flakes.

The Germans give it in fluxes and malignant fevers, being an excellent astringent, and worthy to be introduced into our shops.

Silesiaca TERRA, *Silesian Earth*, in the materia medica, a fine astringent bole, called by some authors *axungia solis*.

It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hands, is naturally of a smooth surface, and is readily diffusible in water, and melts freely into a butter-like substance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acid menstrua. These are the characters by which it is known from all other earths of a like colour. It is found in the perpendicular fissures of rocks near the gold mines at Strigonium in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is, however that be, a good astringent, and better than most of the boles in use. *Hill*'s Hist. of Foss. p. 9.

The *Terra Silesiaca* is also called *Terra sigillata strigoniensis*. *Boyle*'s Works, Vol. I. p. 500, 501.

Montanus gives us a high character of its virtues, and says, it is gold transmuted by nature into an admirable medicine. Sennertus commends it as excellent against malignant fevers, diarrhœas, &c. *Boyle*, ibid.

Agricola tells us, that the spirit of this earth dissolves gold, as well as aqua regia, though more slowly, into a red solution; which, in a few days precipitates the gold in fine powder. He also mentions another earth found at Westerwald, preferable to this Silesian earth. *Boyle*, ibid. See the article WESTERWALD *Earth*.

Sinopica TERRA. See the article SINOPICA *Terra*.

TERRA *Solis*, in natural history, a name given by the German naturalists to a kind of black spungy earth, somewhat approaching to the nature of that English black earth, which we call *kellow*, but containing gold. It is not properly an ore of gold, but is an earth into which some small particles of gold have been washed from some other place, and there detained. A good microscope will discover these particles in the richer pieces of the earth, and they are bright and pure, though very small. The earth is found in fissures of the other strata, not in any beds or strata of itself. It is not to be had in any great quantity, nor does it contain any large portion of gold.

TERRA *Strigonensis*. See the article STRIGONENSIS *Terra*.

Turcica TERRA. See the article TURCICA *Terra*.

TERRA *Virgine aurea*, in natural history, the name of a medicinal earth, mentioned by Boccone.

It is found at a place called Sancto Paolo, in the state of Modena; and is thence sent to Venice, and many other places, where it is esteemed a very famous medicine.

Its great use is in hæmorrhages of all kinds; but it is also given with success in malignant fevers. *Boccone*, Muf. de Fisic.

TERRÆJENBIN, in the materia medica of the antient Arabians, a word used as the name of a kind of manna; it is evidently only a corruption of the word *Tereniabin*, which is plainly that kind of manna now known under the name of *manna persicum*. See the articles MANNA *Persicum*, and TERENJABIN.

TER-

TERRAIGNOL, in the manege, a horſe that cleaves to the ground, that cannot be made light upon the hand, that cannot be put upon his haunches, that raiſes his fore-quarters with difficulty, that is charged with ſhoulders, and, in general, one whoſe motions are all ſhort, and too near the ground.

TERRAIN, in the manege, is the manege ground, upon which the horſe makes his piſte, or tread.

TERRE *Tenant*, *Terræ Tenens*, in law, he who hath the actual poſſeſſion of the land. For example: A lord of a manor has a freeholder, who letteth out his freehold to another, to be poſſeſſed and occupied by him, this third perſon is called the *tertenant*. *Weſt*. Symb. par. 2. *Blount*, *Cowel*.

TERRE *Verte*, in the colour trade, the name of a green earth much uſed by painters, both ſingly for a good ſtanding green, and in mixture with other colours.

The name is French, and ſignifies green earth.

It is an indurated clay, of a deep bluiſh green colour, and is found in the earth not in continued ſtrata or beds, as moſt of the other earths are; but in large flat maſſes of four or five feet in diameter; theſe break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different ſizes. It is of a fine regular and even ſtructure, and very hard. It is of an even and gloſſy ſurface, very ſmooth to the touch, and in ſome degree reſembling the morochthus, or French chalk, but adhering firmly to the tongue. It does not ſtain the hands in touching it; but, being drawn along a rough ſurface, it leaves an even white line, with a greeniſh caſt. It does not ferment with acids, and it burns to a duſky brown colour.

It is dug in the iſland of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been uſed to be eſteemed the beſt in the world; but of late there has been ſome dug in France that equals it. There is alſo an earth dug on Mendip Hills, in the ſinking for coal, which, tho' wholly unobſerved, is nearly, if not wholly, of equal value. *Hill's* Hiſt. of Foſſils, p. 31, 32.

TERRIFICATIO, a word uſed by ſome chemical writers to expreſs the coalition of the earthy particles of ſome bodies after fermentation, or during the time of it.

TERROR. The effect of *Terror*, or of ſudden frights, in diſeaſes, often are very great.

It is generally obſerved, that people who are moſt afraid of the plague in times of contagion, catch the infection ſooneſt, and that thoſe who are moſt terrified and diſheartened at firſt in the diſeaſe, generally die of it. It is indeed uncertain, whether this be to be attributed to the *Terror*, or whether the *Terror* itſelf, as a conſequence of dejection of ſpirits, be not merely a ſymptom of the diſeaſe. *Kerkring*, Spicileg. Anat. Sudden frights, in acute diſeaſes, have evidently killed many, by the agitation into which they have thrown the ſpirits, already too much diſordered. We have alſo accounts of perſons abſolutely killed by *Terrors*, when in perfect health at the time of receiving the ſhock from them: People ordered to be executed, but with private orders for a reprieve, have expired at the block, without a wound. And Kerkring gives an inſtance of a perſon, who, walking along the ſtreets, was foretold by a beggar that ſhe ſhould die on a certain day, then nearly approaching, and who really expired on that day. The world gave the beggar the credit of predicting future events; but the phyſicians rather ſuppoſed that the effects of the *Terror* killed the patient. Id. ibid.

TERSIO, the name given by Pliny, and the antients, to the *porpeſs*. It is ranked among the cetaceous kind, and is the ſmalleſt fiſh of that tribe.

The *porpeſs*, properly ſo called, ſeldom exceeding five feet in length, in which it differs from the dolphin; a fiſh very often confounded with it; but which is frequently ſeen of ten or twelve feet in length. The ſnout of the dolphin is alſo much larger than that of the *porpeſs*; which is another thing that may ſerve to determine their difference.

In the diſſection of the head of this fiſh, the *meatus auditorius* was found to be two inches diſtant from the exterior canthus of the eye, forming a very ſmall hole, which ſeems the provident care of nature, leſt the water, getting in, ſhould prove an inconvenience to it. Ariſtotle and Mr. Ray, indeed, agree in ſaying, that there are no ear-holes found in the head of this fiſh; but a careful inſpection ſhews, that they were both miſtaken.

The *porpeſs* has no gall-bladder, and thence authors have concluded that it has no gall; but this is too haſty a concluſion; for there is a duct which ariſes in the liver, and has a great many branches, and which, tending downwards, joins itſelf to the pancreatic duct; and theſe two, ſo united together, form a canal, or common duct, about four or five lines long, before they diſcharge their contents into the duodenum; from whence it appears that the *porpeſs* has always a diſcharge of bile into the duodenum, though it is thin and diluted, and ſuch as, in other animals, is uſually called *hepatic bile*. *Klein's* Hiſt. Piſc.

TERTHRON, a word properly ſignifying the extreme part of the ſail-yard in ſhipping. Hippocrates uſes it in a metaphorical ſenſe, to expreſs the extremity of a diſeaſe.

TERTIAN (*Cycl*)—The medical writers diſtinguiſh this diſeaſe into two kinds, the ſingle and the double; and beſide theſe, into the legitimate and the ſpurious and ſub-continual. In the ſpurious *Tertian* the cold fits are ſhorter, and the chilneſs leſs intenſe, and the heat ſcarce ever goes off at all; beſide this, it is uſually attended with a cough, and with violent laſſitudes and pains in the limbs after the fits; a vertiginous diſorder in the head, reſtleſsneſs in bed, and a want of appetite.

The ſimple *Tertian* is alſo carefully to be diſtinguiſhed from thoſe acute fevers, principally of the epidemic kind, which frequently affect the appearance of it, when they happen in the ſpring ſeaſon, and the patient is ſubject to crudities in the primæ viæ. Theſe laſt, beſide the appearance of the ſimple *Tertian*, always carry with them the certain marks of malignity, and often are attended with petechial ſpots on the fourth day or later. The juſt diſtinguiſhing all theſe appearances, in diſeaſes that reſemble the ſimple *Tertian*, is extremely neceſſary, as the treatment of them, in the way of the ſimple *Tertian*, muſt be attended with very bad conſequences.

The ſigns of the ſimple Tertian are theſe: It uſually ſeizes people in the morning, frequently about 11 o'clock, and often earlier, and begins with a very remarkable horror and coldneſs, with which the patient trembles violently: This is firſt felt in the region of the loins, and thence propagates itſelf up the back, and ſo to every part of the body; this is ſucceeded by a nauſea, and a ſtraitneſs of the præcordia; and when the *Tertian* is legitimate and genuine, this nauſea proceeds to abſolute vomiting, by which there is uſually voided a thick viſcous and mucous matter; but ſometimes a bilious ſaburra; and in the firſt fits, uſually ſome of the food of the day before, indigeſted. Sometimes there are only violent reachings to vomit, without any thing coming up; and in ſome a diarrhœa comes on in the place of the vomiting. When theſe ſymptoms have continued an hour or two, the coldneſs goes off, and there ſucceeds an univerſal languor and ſoreneſs in the joints; and this is the more violent, as the nauſea has been the leſs ſo. This languor is followed by a violent heat, which ſometimes comes on at once, and ſometimes ſlowly and gradually, and is attended with pains in the head, and a violent thirſt, and bitter taſte in the mouth. *Junker's* Conſp. Med. p. 364.

As ſoon as the violence of the heat abates a little, a ſweat comes on; but this is not great, and often does not appear at all in the firſt paroxyſms. The more ſtill and quiet the perſon is, the more quickly the heat goes off, and the ſweating comes on. The whole fit rarely continues leſs time than ſix hours; uſually it holds eight, and ſometimes eleven hours; but when it continues longer than this, it is to be ſuſpected for being of the ſpurious kind, and degenerating into a continual one. The fit returns in the ſame manner as at firſt every other day, or, as the medical writers term it, every third, including the days of both paroxyſms; and uſually, while undiſturbed, returns on the patient at the very ſame hour.

The double Tertian. The ſigns of this are, that the fits return every day; but then the ſucceeding paroxyſms do not anſwer to one another; but the alternate ones; thus the third fit anſwers to the firſt, the fourth to the ſecond, and ſo on. It is by this, that this diſeaſe is diſtinguiſhed from the quotidian, which has its fits every day coming on at the ſame hour; while in the double *Tertian*, if the firſt fit comes on in the morning, the ſecond comes in the afternoon; then the third comes on in the morning as the firſt, the fourth in the afternoon as the ſecond, and ſo on.

The anomalous *Tertian* obſerves no regular time of coming on at all, but will begin one day in the morning, another in the evening, a third at noon, and a fourth in the afternoon, and ſo on.

Perſons ſubjects to TERTIANS. Young people are much more frequently ſubject to this diſeaſe than older, and men oftener than women. People of an active life are more ſubject to it than thoſe of a ſedentary one: But no people ſo eaſily fall into it as thoſe men who are apt to be ſick after dinner, and make a cuſtom of ſuppreſſing their inclination to vomit.

Cauſes of it. Theſe are the eating immoderately of foods difficult of digeſtion, and eſpecially when this is done againſt the ſtomach, or while that is afflicted with nauſeas, violent commotions of anger, or the other paſſions, immediately after a full meal; and to theſe is to be added, a coldneſs of the abdomen after meals, by which digeſtion is impeded, and the driving back any cutaneous humour.

Prognoſtics and Method of Cure. It is commonly obſerved, that *Tertians*, when not improperly treated, are rather conducive to health, than injurious to it; and that people are uſually much better after they are cured of them, than before they were attacked by them. If thoſe who have a *tertian* uſe a moderate diet and good regimen, it often goes off of itſelf, without the aſſiſtance of medicines; but when ill treated, as by giving violent ſweating medicines in the time of the hot fit, the patients are greatly weakened, and ſometimes very dangerous inflammations of the viſcera, and acute fevers are brought on; and this the more certainly, as the patient is younger, of a more plethoric habit, and uſed to a high diet, and the uſe of wine, or other ſtrong liquors.

The more the gentle ſweat, which ſucceeds the hot fit, is encouraged, the weaker the fits grow at every period, and the diſeaſe

disease finally goes off much more safely by this means, than when violently thrown off at once by astringents.

The *double Tertian* requires the same method of cure with the simple one; for which see the articles PERUVIAN *Bark*, and AGUE. *Junker*'s Consp. Med. p. 366.

Continual TERTIAN, in medical writers, a term used to express a kind of compound fever, which has paroxysms something like those of the *Tertian*, but in which the heat never goes wholly off; but is often so extream, as to continue in great violence from one fit to the time of another.

There are three species of these compound fevers; they are all composed of the intermittents of the several periods, and of an acute fever: The first is the *continual quotidian*, the second this *continual Tertian*, and the third the *continual quartan*.

The first of these is the same with the catarrhal fever of the benign kind. The second here treated of, is what was called by the antients, the *extended Tertian*. For the *continual quartan*, see the article QUARTAN.

Signs of it. The paroxysms are begun in the same manner as in the simple *Tertian*, that is, by a shaking coldness; and this is succeeded by a heat which is at first very violent, but afterwards grows more and more languid, yet never goes wholly off, but continues, in some degree, to the access of the next paroxysm. In this disease the appetite is lost, and the strength fails very sensibly, the sleep is troubled and unsound, and there is a continual head-ach; there is a quick pulse at all the times of the fever, and a dryness of the mouth and tongue, with great thirst. *Junker*'s Consp. Med. p. 396.

Persons subject to it. This fever is very often the consequence of a common simple *Tertian*, when injudiciously treated, especially when it has been suppressed by giving hot medicines just before the coming on of the fit, or when the patient has been cooled in the time of the sweat, or has been blooded during the time of the disease; it sometimes also attacks persons who have had violent cutaneous humours, as the itch, &c. struck in; and sometimes the air alone gives it, from being full of fermentative particles.

Prognostics in it. When the disease is of this epidemic kind, and arises from faults in the air, it is always attended with greater danger, and has worse symptoms than when proceeding from other causes; in this case it is sometimes attended with purple spots on the breast and other parts. When treated cautiously, and with a gentle regimen, it very often changes to a common intermitting *Tertian*, and is then easily cured; but even from this less dangerous state, it sometimes changes into a hectic, when it has been treated with large doses of absorbents under that form; and finally, when it is treated with the common hot medicines and regimen, it too often degenerates into a violent and dangerous acute, and usually inflammatory fever.

Method of Cure. Before the coming on of every fit, the patient should take a scruple of a powder, prepared of diaphoretic antimony, oister-shells sated with juice of lemons, nitre, and tartarum vitriolatum, each in equal quantities; and while the heat continues violent, he must drink plentifully of warm and weak liquors; and when this violent heat is gone off, he must be kept in a gentle sweat, by the milder alexipharmics, till the return of the paroxysm again.

In cases where the heat is very violent, and the temperament of the body is hot and plethoric, the acids, such as lemon-juice, and the like, are of very singular service. During the whole course of the disease, the bowels must be kept open by all means; but they must not be stimulated; and as the force of the distemper wears off, more powerfully laxative medicines are to be given, and that at such times that their effect may not be over at the time of the access of the paroxysm.

The bark can properly have no place in the cure of this disease; and after the cure of it by the means above prescribed, the patient must continue the use of some of the medicines, and must harden himself to the air by degrees, for fear of a relapse. *Junker*'s Consp. Med. p. 399.

TERTIANARIA, in botany, a name given by some authors to the *scutellaria*, or hooded willow herb. *J. Bauhin.* vol. 3. p. 435.

TERTIAS, a word used very frequently in the writings of physicians, with the addition of *ad*; but it is capable of a double signification. *Ad Tertias* is often used to express how far the liquor is to be boiled away in medicinal decoctions; yet it may in this case signify either the boiling to two thirds, or to one third part, of the whole. The more usual sense, however, is to boil away one third part of the original liquor, and in the same manner to fill a vessel *ad Tertias*, does not signify to fill a vessel one third part full, but two thirds, leaving only one empty.

TERTIUM *Sal*, a *third salt*, a term used in chemistry to express a salt resulting from the mixture of an acid and an alkali, which partakes so of the nature of both, as to be itself neither acid nor alkali, but neutral.

TERTIUS *Adducens*, in anatomy, a name given by Spigelius to one of the four muscles called the *quatuor recti oculi* by authors.

This is the muscle called the *adductor* by Molinett; and by some others, the *bibitorius*.

TERTIUS *Hyoidis Musculus*, in anatomy, a name given by Fabricius and others, to the muscle generally known by the name of *stylohyoidæus*.

TERTIUS *Oculum Movens*, in anatomy, a name given by Vesalius to one of the muscles called by Albinus, the *quatuor recti* of the eye; this is the same with the first of that author, the *atollens oculi*, the *superbus* of others.

TERTIUS *Palpebrarum*, in anatomy, a name given by some authors to the muscle called by Albinus and others, *obliquus superior oculi*.

TERTIUS *Thoracis*, in anatomy, a name given by many of the earlier writers to a muscle now called *serratus posterior superior*. See the article SERRATUS.

TERZETTO, in the Italian music, a little tune or air in three parts. See the article TRIO.

TERZO, in the Italian music, sometimes signifies a composition consisting of three parts, or designed for three voices or instruments.

It is also used for a third part of any thing, as *un Terzo di battuta*, a third part of the bar. See the article TRIO.

TERZOLA, in botany, a name by which some authors have called the *eupatorium cannabinum*, or water hemp agrimony. *Ger.* Emac. Ind. 2.

TESSARACONTA, Τεσσαρακοντα, among the Athenians, were forty men who went their circuits round the several boroughs, and had cognizance of all controversies about money, if not above ten drachms; as also of actions of assault and battery. *Potter*, Archæol. Græc. T. 1. p. 122.

TESSARACONTERIS, in the naval architecture of the antients, a word used to express a sort of galley, in which there were no less than forty tires of rowers one above another.

Many have doubted whether such monstrous vessels as these were ever built; but we have absolute accounts of one such of Philopater's, which must have required above four thousand men to manage the oars.

Ptolemy Philadelphus is said to have had one with thirty tires of rowers, requiring three thousand men; and we have accounts of another at the same time of twenty tires, requiring two thousand: But tho' such vessels as these were really built, we are not to suppose they were common. The triremes, or those gallies which had three tires of rowers were found the most serviceable of all others; and from these they built pretty frequently up to the enneeres, which contained nine rows or tires; and these were the largest ever brought into common use, as is fully proved by Meibom against Salmasius, on the authority of Pliny, Plutarch, and Polybius. *Meibom.* de Trirem.

This author has also taken off much of the imaginary height necessary, according to common computation, for these vessels, having found a more convenient way of placing the rowers.

TESSARACOSTON, Τεσσαρακοστον, in antiquity, a solemnity kept by women on the fortieth day after child-birth, when they went to the temple, and paid some grateful acknowledgments for their safe delivery. *Pott.* Archæol. Græc. T. 1. p. 432. and T. 2. p. 335.

TESSELÆ, a word used in pharmacy to express lozenges cut into regular figures.

TESSELARII, among the Romans, artificers of chequered or mosaic work. See the article MOSAIC, *Cycl.*

TEST, (*Cycl*) in metallurgy, is a vessel of the nature of the coppel, used for large quantities of metals at once. The coppels or small vessels made of ashes, serve for operations of this kind, when small quantities only are concerned; but when larger are worked on, vessels of a larger size and coarser texture are employed, which are distinguished by the name of *Tests*.

These are usually a foot and half broad, and are made of wood-ashes, not prepared with so much care as for coppel-making, and mixed with finely powdered brick-dust; these are made into the proper shape either by means of an earthen vessel of proper dimensions, or only an iron ring.

To make them in the first manner, an earthen vessel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked; the inside of this vessel is to be well moistened with fair water, that the ashes to be put into it may adhere the better. Put into this vessel, thus prepared, the ashes and brickdust before-mentioned, and first moistened either with water alone, or with water with a little white of an egg mixed in it; let the quantity of this be so much as will half fill the vessel, then press the mass with a wooden indented pestle, or, if not for a very large *Test*, with a wooden cylinder, only of an inch thick: When thus pressed down, add fresh ashes, and press them in a second time, as in the making of coppels, and repeat this addition of fresh ashes till the earthen vessel be nearly full; then remove the superfluous ashes with an iron ruler, and let the inequalities remaining at the border be smoothed with a wooden ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad spherical segment, not very deep: And lastly, by means of a sieve, strew this cavity carefully and regularly over with dry ashes of bones of animals, ground extremely fine, and squeeze these hard

hard in, by the rotation of the wooden ball. Thus you have a *Teſt* finiſhed, which, together with its earthen pot, muſt be ſet in a dry warm place.

To make the *Teſts* in the other manner, or by means of an iron ring, let a ring of that metal be filled with aſhes mixed with brickduſt, and moiſtened as before-mentioned, in ſuch manner that they may riſe conſiderably above the ring; then preſs them ſtrongly either with your hands, or with an indented peſtle, and afterwards, with gentle blows of a rammer, preſs the aſhes from the circumference toward the center, in a ſpiral line, and that in ſuch manner, that, after having been ſufficiently preſſed, they may be a ſmall matter higher than the brink of the ring. If there are now any vacancies in the maſs, empty the ring, and fill it again with more aſhes; for if you ſhould attempt to fill up theſe by adding, were it but ever ſo little aſhes, the ſecond, or additional quantities, will never cohere ſo firmly with the firſt, but that they may probably ſeparate in the operation.

This done, turn the ring upſide down, and on the other ſide, or bottom, take out the aſhes to the quantity of one third part of the depth of the ring, and again fill the vacuity with the ſame aſhes, in ſuch a manner that there may remain no ſenſible cavity.

When the maſs is thus prepared, cut out a cavity in the larger ſurface of the ring, with a bowed iron, as in the former method.

The Germans have, beſide theſe, another kind of *Teſts*, which they call *treibſcherben*. Theſe are a ſort of veſſels which reſiſt the moſt violent fire, and are ſo extremely compact, that they ſometimes will retain not only melted metals, but even the glaſs of lead itſelf.

The figure and ſize of theſe veſſels may be the ſame with that of the coppel, but they are uſually made larger; and the great difference of theſe *Teſts* from coppels, and from the ordinary *Teſts*, which are indeed only a kind of large and coarſe coppels, is, that the matter of theſe is more compact and coherent.

The matter for the making theſe *Teſts* is thus prepared: Take of the pureſt and fineſt clay a ſufficient quantity, make it into balls, and dry them either in the air, or in the fire; when dried, beat them to powder in a mortar, and pour on the powder a great quantity of warm water: Let this mixture reſt a while, and when the clay has ſubſided, pour off the water which ſwims at top; and let this waſhing be ſo often repeated, that all the moſt minute lumps of the clay be broken, and whatever ſalt it contains perfectly waſhed out: Then add to this fine clay, of the pureſt ſand, of powder of calcined flints, ground, and well waſhed, of faulty, but clean Heſſian crucibles, or of any incombuſtible ſtones ground very fine, ſuch a quantity as will render the maſs thick, and hardly adhering to the hands in kneading it, or pliant when rolled into a thin lamina.

This is the matter for making this ſort of *Teſts*; but before any quantity of the veſſels be made of this earth, it will be prudent firſt to finiſh a ſingle one, and try it, by putting on it a quantity of glaſs of lead, and expoſing it for an hour or more to the ſtrongeſt fire; by this trial you will be certain whether or not the maſs is capable of making veſſels that will reſiſt both the fire and the glaſs of lead; and by no other means but this trial is it poſſible to determine the due proportion of the mixture of the ingredients for this uſe, on account of the variety of the clays. Nature in ſome places affords a clay ſo well tempered, that it is extremely proper for the making of *Teſts* without any preparation, or without the admixture of any other matter. Sometimes this only requires a ſimple waſhing, but commonly it is neceſſary to make it into balls, and powder and waſh them as before directed.

On the trial of a *Teſt* made of this, or the former mixed clay, if it runs into glaſs, you muſt add to it of the powder of ſtones, eſpecially ſuch as beſt reſiſt the fire. Great care is to be taken not to add too much powdered chalk to theſe compoſitions, ſince if the matter is tempered with that alone, the *Teſts* will indeed reſiſt the fire very well, but being too porous, they will yield a paſſage to litharge, which will ſoften them to ſuch a degree, that they will either fall aſunder of themſelves, or be totally cruſhed when taken hold of with the tongs.

Theſe veſſels are to be made in the following manner: Rub over the ſides and bottom of a ſmall mortar, and alſo its peſtle, with oil, or with the fat of bacon; fill it two thirds full of prepared clay, then make a ſlight impreſſion with your fingers in the middle of the clay; then place the bottom of the peſtle there, and force it down with blows of a hammer, the ſtronger the better. When thus properly hollowed, take it out of the mortar, and pare its edges, and dry it as the coppels are dried, in the air, in a dry warm place. *Cramer*'s Art of Aſſ. p. 60, 62.

Teſts, thus prepared, may be uſed as ſoon as dry, unleſs for ſalts, or litharge; but theſe bodies, when melted in veſſels not firſt baked or hardened in the fire, always make their way thro' them.

TEST *Liquor*, a term uſed by our dealers in brandies, &c. for a liquor which they uſe as the *Teſt* of brandy, &c. to prove whether they be genuine, or mixed with home ſpirit.

The people who uſe this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend, that this liquor will ſhew by the colour which it makes, on being poured into brandy, whether it be genuine and unadulterated; or if not, in what proportion the adulterating ſpirit is mixed with it.

The whole fact is this: If a little common green or white vitriol be diſſolved in ſome fair water, it makes a *Teſt* liquor; a few drops of which being let fall into a glaſs of old French brandy, will turn the whole to a purple, or fine violet-colour; and by the ſtrength or paleneſs of this colour, the dealers judge the brandy to be genuine or mixed, in different proportions, with home ſpirits.

Old French brandy, having long lain in the caſk, takes a dilute tincture of the wood of the caſk, that is, of oak; and this being of the ſame nature with a ſolution or tincture of galls, naturally turns bluiſh or blackiſh with vitriol. A new diſtilled brandy, tho' wholly foreign, would not give this *Teſt*; and a common malt ſpirit, with oak chips infuſed in it, will turn as dark as the fineſt brandy. While our diſtillers indeed had nothing in uſe for the colouring their ſpirits but burnt ſugar, it was poſſible to make ſome gueſs at an adulteration with them, becauſe the brandy, in this caſe, would not become blackiſh in proportion to its former colour, the ſugar-colour not turning to ink with the vitriol like the other: But our diſtillers have of late found a way of uſing an extract of oak for the colouring of their ſpirits, and, ſince that, this *Teſt-liquor* is of very little uſe, our common ſpirits, of any kind, turning as deep with it as the foreign brandies.

The very beſt way of making this *Teſt-liquor*, is with a calcined vitriol of iron, diſſolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the fineſt blue to any ſpirituous tincture of oak.

The Engliſh were, at one time, very fond of high-coloured brandies, and it was then that the uſe of this *Teſt-liquor* was moſt eſteemed; afterwards we, as well as other nations, finding that this colour was only owing to the caſk, began to diſlike it, and to favour the pale brandies: At length we fell into the uſe of ſuch as were wholly limpid and colourleſs, and the re-diſtilling of all the old brandies people were poſſeſſed of took place; on this, the *Teſt-liquor* was found to be of no uſe at all, and accordingly rejected; but as we are of late again come into the eſteem of coloured brandies, and that with great juſtice, as the colour, when genuine, is a certain mark of the age of the liquor, this *Teſt-liquor* is again got into more credit than it deſerves.

The famous Helvetian ſtyptic depended wholly on this accident for its colour; and it was no ſmall mortification to our chemiſts, when, ſome years ago, it was introduced into uſe among us, that they could not make it with our own ſpirits, but muſt be at the expence of true French brandy for it; our own ſpirits, though equally coloured, would never make that violet tincture, becauſe their colour was owing to burnt ſugar, not a tincture of oak. At length this myſtery was explained, and a little ſcrapings of galls made all thoſe quantities of this ſtyptic, which had been ſet by as good for nothing, perfectly fine and well coloured. *Shaw*'s Eſſay on Diſtillery.

TESTA, in antiquity, the ſame with *oſtracon*. See the article OSTRACON.

TESTES (*Cycl.*) Theſe are wanting in moſt of the fiſh kind. The ſpinoſe fiſhes in general have neither *Teſtes* nor paraſtatæ; but all the cetaceous fiſhes have them, and not a few of the cartilaginous kinds. Thoſe fiſh that have them, have always two, as in land animals; but they differ much in figure and ſituation in the ſeveral kinds, particularly in the whale and flat fiſh. *Artedi* Ichthyol.

TESTICLE (*Cycl.*) *Tumours in the* TESTICLES. Tumours and inflammations of one or both the *Teſticles* are not unfrequently the conſequence of falls, blows, and contuſions, and very often are alſo brought on by venereal diſorders.

The beſt external applications to diſperſe theſe are vinegar of litharge, lime-water, ſpirit of wine camphorated, and ceruſs, tutty, or lapis calaminaris mixed in it. But in the night-time, when the applications of fomentations are not ſo convenient, a plaſter of the mercurial kind, doubly ſated with mercury, or, in ſlight caſes, one of ſimple diachylon, may very properly be kept on. Internal medicines, ſuch as nitre, and the thin decoctions of diſcutient remedies, are to be uſed; and, if occaſion call for it, bleeding in the arm is very proper.

This may be the method with tumours of theſe parts, from external injuries; but when they are from venereal cauſes, it is always neceſſary to give briſk purges, with the addition of a proper doſe of calomel to each, and warm and weak drinks ſhould be taken frequently, and by this means theſe tumours are often diſperſed. But if either remedies are applied too late, or the inflammation is very violent, the tumour generally ends either in a ſuppuration or gangrene. In this caſe the maturating remedies are to be applied, ſuch as warm cataplaſms, and the like; and if the tumour does not break of itſelf at a proper time, from the application of theſe, it muſt be carefully opened with the knife, and the matter being diſcharged, the wound is to be cleanſed by injecting vulnerary decoctions with a

a syringe, and afterwards healed by the balsams, as that of Peru, or the like.

The taint that occasioned the tumour is sometimes wholly eradicated, and the patient freed from it by a proper management of these abscesses. It not unfrequently happens indeed in them, that the scrotum is in part consumed, so as to leave the part bare, but this loss of substance may generally be restored by proper treatment, with digestive and balsamic remedies. *Heister's* Surgery, p. 191.

TESTICULATED *Roots*, are those composed of two tuberose knobs, resembling a pair of testicles. Of this kind are the orchises, *&c.*

TESTICULI *Musculus*, in anatomy, the name given by Fallopius, and some others, to the muscle now generally known by the name of the *cremaster*.

TESTO, in the Italian music, is applied to those words of a song, to which some air or tune is to be composed.

It is a matter of great importance in music, to understand well how to appropriate or adapt the music to the words of a song, to express the sense, and make a just application of the long and short syllables to the notes and times with which they are to be connected.

But this branch of the science, which depends greatly on the knowledge of poetry, has lain a long time almost unregarded, and even at present very little care is taken with respect to this in the modern music.

TESTUDO (*Cycl.*)—TESTUDO, the *Tortoise*, in the Linnæan system of zoology, makes a distinct genus of animals; the characters of which are, that the body is defended by a thick crust, and is furnished with a tail. *Linnæi* Syst. Nat. p. 50. See Tab. of Quadrupeds, N°. 28.

The *Tortoise* is a well known animal, of which there are several species. The shell, which covers this creature's body, is composed of a number of variously shaped pieces, often pentangular; these are affixed to a bony substance, like the skull of some animals, which surrounds the animal, and has two apertures; one before, which gives way to the going out of the head and the fore-legs; and the other behind, through which the hinder legs and thighs are protruded.

This bony substance is, in different parts of very different thicknesses; in some places an inch and half, in others not an eighth part of an inch. It is composed of two pieces, the one covering the creature's back, the other its belly; these are joined at the sides by very strong ligaments, but not so rigidly closed but that they easily give way to the creature's motions. *Ray's* Syn. Quad. p. 253.

This is the general order of nature in the structure of the shell of this creature; of which we have several species in different parts of the world, the shells of which are of different value.

1. The common *Tortoise*. This is variegated with black and yellow spots and lines on the back. The upper shell is extremely convex, and the under one flat. Its head is small, and like that of a snake, and it can thrust out this, or draw it into the shell at pleasure. It has no eye-lids, nor any external ears; this is a very long-liv'd creature, and passes the winter without food under ground.

2. The *Jaboti* of the Brasilians, called by the Portuguese *Cagado de Terra*. This has a black shell with several hexagonal figures engraved on it; the head is like that of the other kinds, and is brown, as are also the legs, but variegated with spots of a dusky greenish hue. The liver of this species is esteemed a very delicate dish.

3. The *fresh-water Tortoise*, or the *mud-Tortoise*. This lives in muddy places, frequently in the ditches that surround the walls of towns. The shell of this kind is scarce at all convex on the back, and the creature very disagreeable and ugly; it is also remarkable for the length of its tail, which is slender and tapering like a rat's. The shell is black, and is composed of several small pieces nicely joined together: it can at pleasure thrust out its head, or draw it back into the shell; it feeds on snails, insects, *&c.* and will live a long time without any food; and even when the head is cut off will retain motion and an appearance of life in the limbs and body for a long time.

4. The *common Turtle*, or *Sea-tortoise*. This much resembles the common land *Tortoise*, but that it is larger, and its shell much less beautiful and softer. Its feet are made like the fins of fishes, and well adapted for swimming. They have on each jaw a continued series of bone, which is received in a sinus in the opposite jaw, and serves to chew with.

They come out of the sea to lay their eggs, which they deposit on the earth in prodigious numbers; one female sometimes laying an hundred, and these are left to be hatched by the heat of the sun.

5. The *Jurucua* of the Brasilians, or *Tartaruga* of the Portuguese, called also the *Frank Tortoise*. This has a sort of fins in the place of feet, the fore-ones six inches long each, the hinder ones considerably shorter; and their shells are very elegantly variegated with different figures. *Ray's* Syn. Quad. p. 258. See the article JURUCUA.

6. The *Cawuanne Tortoise.** This is a sea-kind, much resembling the former in shape; but the shell is thicker, and the flesh but ill tasted.

7. The *Carette Tortoise*. This is a small kind, and does not deposit its eggs in the sand, as the others; but lays them among gravel and heaps of small pebbles. The flesh of this species is but ill tasted, but its shell is extremely valuable for ornamental works.

8. The *Jurura* of the Brasilians, or *Cagado d'Agoa* of the Portuguese. This is smaller than the other kinds, and its shell is of an elliptic figure. The shell of this species is considerably convex on the back; its head is long, and its tail short. Marggrave kept one of this species in his house one-and-twenty months without food.

9. The *small East-Indian Land-Tortoise*. This is not above three inches long, when at its full growth; its shell or crust is composed of three orders of scales, and a general rim surrounding them all. Its colours are white, purple, yellow, and black, and it is a very beautiful kind; when the scales of this shell are taken off, the vestiges of them are plain in a mottled black and white colour, with some yellowness. The lower shell is white, and marked with a great number of beautiful lines. The head and beak in this species, are like those of the parrot; and the upper part of the head is variegated with red and yellow; the neck is slender, and the fore-legs are covered with small scales. The feet are flat, and are divided into four toes. The hinder legs are much longer and slenderer than the fore ones, and are only covered with a tough skin; the feet however of these are scaly, and have four toes, as the others. The tail is slender and tapering, and about three inches long. *Ray's* Syn. Quad. p. 259.

10. The *lesser chequered Tortoise*, marked with stars. The shell of this is about seven fingers breadth long, and five wide; it is black, and marked out into rhomboidal figures; and is composed of three orders of prominences, beside the general surrounding rim; from the middle of these eminences there arise five, and from the sides four tubercles, from which there are a number of stellar figures radiated. The lower shell consists of eight pieces, two of which are much larger than the rest, and this is of a blackish and yellowish mottled colour.

11. The *great chequered Tortoise*. This species is found in the island of Madagascar, and is the most convex of all the *Tortoises*. It is a foot long, eight fingers broad, and six high. This is the size of one kept in the Museum of the Royal Society.

12. The *tessellated Surinam Tortoise*. 13. The *tessellated Virginian Tortoise*. And, 14. The *scaly Tortoise*. This is of the mud or fresh-water *Tortoise* kind. It is usually about a foot long, ten inches broad, and three and a half high; and the middle of the back rises into a very remarkable longitudinal ridge. This is somewhat allied also to the *carette Tortoise*. *Ray's* Syn. Quad. p. 260.

TETARTEMORION, among the antients, denotes the fourth part of the zodiac. *Pitisc.* in voc.

TETHALASSOMENOS, a term used by the old medical writers, to express wine mixed with sea-water.

TETIMIXIRA, in zoology, the name of an American fish, more usually known by the name of the *Pudiano*. It is a small fish resembling a pearch, with a purple back, and yellow sides and belly. *Marggrave's* Hist. Brasil. See the article PUDIANO.

TETRACERA, in botany, the name of a genus of plants; the characters of which are these: The cup is a six-leaved perianthium. The leaves are roundish, and stand expanded. There are no petals so far as can be seen in the dried specimens, and the growing plant has not been examined since the time that Houston was deceived by its external resemblance with the petræa, and described its fruit and the flowers of the petræa under the character of one genus, which he called petrea. The stamina are numerous simple filaments, of the length of the cup; they are permanent also, and the antheræ are simple. The germina of the pistil are four in number; they are of an oval figure, and gape open one from another. The styles are subulated, and very short; and the stigmata are obtuse. The fruit is composed of four capsules, which are oval and crooked; and are composed of one valve containing only one cell, and opening at a suture near the top when ripe. The seeds are single and roundish. *Linnæi* Gen. Plant. p. 249.

TETRACHORD (*Cycl.*)—The names of the sounds of a *Tetrachord*, considered by itself, were hypate, parypate, paranete, and nete. Aristoxenus calls them hypate, parypate, lychanos, and nete. *Wallis's* Append. at *Ptolem.* Harm. p. 159, 160.

When *Tetrachords* came to be joined, the parypate was sometimes called *trite*, as being the third from the *nete*; and the paranete was sometimes called lychanos, as in the fore-mentioned place of Aristoxenus. *Wallis*, ibid. See the article LYCHANOS.

The *Tetrachord of Mercury*, contained four strings or chords, in the proportions of 12, 9, 8, and 6; so as to give the fourth, fifth, and octave of the lowest chord. This is the opinion of Boëthius, and after him of Zarlino. Vid. *Wallis's* Append. Ptolem. Harm. p. 178.

TETRACTIS, in natural history, a name given by Linkius, and other authors, to a kind of star-fish, composed only of four rays, the more common kinds having five.

TETRA-

TETRADECARHOMBIS, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ.

The word is derived from the Greek τετρὰς, four, δεκὰς, ten, and ῥόμβος, a rhomboidal figure, and expreſſes a rhomboidal body conſiſting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the ſame form with the common ſelenitæ; but that in theſe each of the end planes is divided into two; and there are by this means eight of theſe planes, inſtead of four. *Hill's* Hiſt. of Foſſ. p. 120. See the article SELENITES.

Of this genus there are only three known ſpecies. 1. A thin pellucid one, with tranſverſe filaments; which is frequent in the clay-pits of Northamptonſhire, and ſome other counties. 2. A dull thicker kind, with very ſlender tranſverſe filaments; this is a very rare ſpecies, and found as far as is yet known only in Leiceſterſhire in the yellow brick clay, and at ſmall depths. And, 3. A large ſcaly kind, conſiderably long, and of a very rough ſurface; this is found in Yorkſhire, and that ſometimes looſe on the ſides of the hills, but more frequently buried in the ſtrata of clay. *Hill's* Hiſt. of Foſſ. p. 133, 134, 135. See Tab. of Foſſils, Claſs 2.

TETRADYNAMIA, in botany, a claſs of plants, whoſe flowers have four of their ſtamina of more efficacy than the reſt: Theſe are always known by having the four efficacious ſtamina longer than the reſt.

The word is formed of the Greek τετρὰς, four, and δυναμὶς, power. Of this claſs of plants are ſcurvy-graſs, muſtard, radiſh, &c. See Tab. 1. of Botany, Claſs 1.

The *Tetradynamia* of Linnæus include thoſe called by Tournefort *cruciformes*, and by Ray *ſiliquoſæ*, and *ſiliculoſæ*. The general characters of the claſs are theſe:

The perianthium is of an oblong figure, and is compoſed of four leaves, which are oval, oblong, hollow, obtuſe, and converging toward one another, and are gibbous at the baſe; theſe all fall off with the flower, and ſtand in pairs; the oppoſite ones being always equal in length, this cup is properly the nectarium of the plant, and it is on this occaſion that it is gibbous at the baſe. The flower is of that kind, called by Tournefort, *cruciform*; it conſiſts of four equal petals, which have ungues of the length of the cup, erect, and flat; the petals are broad at the top, and obtuſe, and ſcarce touch one another at the ſides; and the inſertion of the petals and of the ſtamina is in the ſame place.

The ſtamina are ſix ſubulated erect filaments, the two oppoſite ones are of the length of the cup, the other four are ſomething longer, and are of a leſs length however than the petals. The antheræ are oblong and pointed, thick at the baſe and erect, with apices bending ſideways. The nectariferous gland in the different genera of this claſs is differently ſituated. It uſually however is found near the ſtamina, and moſt frequently of all is affixed to ſome ſhort filaments, and ſtands near their baſe. Two of the ſtamina are often curved, that they may not preſs upon this gland; and it is often owing to this, that two are ſhorter than the reſt. The germen of the piſtil is placed above the receptacle, and is every day in its growth raiſed higher and higher. The ſtyle is ſometimes wanting, but in ſuch plants as have it, it is of the length of the longer ſtamina. The ſtigma is always obtuſe.

The fruit or capſule is always a bivalve pod, which often contains two cells; this, when ripe, opens by ſplitting from the apex to the baſe, and it has always a little membranous ſubſtance ſerving within as a ſeptem, when the pod is bilocular; this ſtands out beyond the apex, and is the rudiments of what was before the ſtyle. The ſeeds are roundiſh, and the pod uſually narrow and oblong.

This is a very natural claſs of plants, and has been received as ſuch under whatever name by all the ſyſtematical writers in botany.

The plants of this claſs are generally ſuppoſed to be all antiſcorbutics. This claſs of plants is naturally ſubdivided into two ſeries: The one containing the ſiliculoſe plants, and the other the ſiliquoſe. The firſt have a ſhort pod, the others a long and ſlender one. The firſt pods uſually have more of the remains of the ſtyle than the others. *Linnæi* Gen. Plant. p. 309.

TETRAETERIS, τετραετηρὶς, in the Athenian chronology, a cycle of four years; for which ſee *Potter*, Archæol. Græc. l. 2. c. 26. T. 1. p. 459, ſeq.

TETRAGONIA, in botany, the name given by Linnæus to a genus of plants called by others *Tetragonocarpos*. The characters are theſe: The cup is compoſed of four oval coloured leaves, curled at their edges, and remaining after the flower is fallen. There are no petals. The ſtamina are twenty capillary filaments, ſhorter than the cup. The antheræ are ſhort, and incumbent. The germen of the piſtil is roundiſh, quadrangular, and placed under the receptacle. The ſtyles are four, ſubulated, crooked, and of the length of the ſtamina. The ſtigmata are longitudinal and hoary. The fruit is a coriaceous cruſt, formed into a kind of ſquare figure, by four longitudinal alæ. The ſeed is ſingle, oſſeous, and contains four cells, with oblong nuclei. *Linnæi* Gen. Plant. p. 249.

TETRANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with four ſtamina or male parts in each. See Tab. 1. of Botany, Claſs 1.

The word is formed of the Greek τετρὰς, four times, and ἀνὴρ, male. Of this claſs of plants are the teaſel, madder, plantane, &c.

TETRANGURIA, in botany, a name uſed by ſome authors for the citrul, a plant of the gourd kind, whoſe ſeeds are uſed in medicine. *Chabræus*, 133.

TETRAO, in the Linnæan ſyſtem of zoology, the name of a genus of birds of the order of the gallinæ; the diſtinguiſhing characters of which are, that the feet have each four toes, and the eyelids are naked and full of fleſhy tubercles. Of this genus are the pheaſant, partridge, quail, &c. *Linnæi* Syſt. Nat. p. 48.

TETRAO, is alſo uſed for a large bird of the gallinaceous kind, whereof there are two ſpecies, the one larger, and the other leſſer; they are called alſo by authors, the *urogallus major*, and *minor*.

The larger is common in Italy, and on the Alps; ſee the article UROGALLUS. The leſſer is common in ſome parts of England, and is called the *black game*, or the *grouſe*. *Ray's* Ornithol. p. 123. See the article GROUSE.

TETRAPHOE, in botany, a name given by the people of Guiney to a plant, which they give in decoction as a cure for fluxes. This plant grows alſo in Malabar, where they uſe the roots boiled in whey in the piles; and in the colic they give the root in powder, about a ſcruple for a doſe. It is called in this latter place *wellia cadavalli*, and by Petiver *xanthium malabaricum capitulis lanuginoſis*. The ſtalks of it are woody and hoary, eſpecially about the tops. Its leaves ſtand by pairs on ſhort foot-ſtalks, and while young they are hoary underneath, with a very ſoft and velvety down; the others are rough like the ſpotted lungwort, but ſeldom are ſo large. The flowers grow in ſpikes, and conſiſt each of fine green leaves filled with ſcarlet filaments: After theſe the fruit ripens, and is a ſort of woolly bur covered with ſoft and hooked prickles, very like the common Engliſh burdock, but not of a third part of the bigneſs. Phil. Tranſ. Nº. 232.

TETRAPYRAMIDIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek τετρὰς, four, and πυραμὶς, a pyramid.

The bodies of this genus are ſpars influenced in their ſhape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four ſides.

Of this genus there is only one known ſpecies, which is uſually of a browniſh colour, and is found in Saxony; as alſo in Devonſhire, Cornwal, and other counties of England, where there is tin. *Hill's* Hiſt. of Foſſ. p. 378.

TETRASTŒCHON, in botany, a term often uſed by the the Greek writers, and generally miſunderſtood by thoſe who copy their accounts. Pliny has made an error in the deſcription of the euonymus, which has confounded two different ſhrubs together ever ſince, by miſtaking the ſenſe of this word, uſed by Theophraſtus in his account of it. He ſays, that the fruit is divided within into four orders or ſeries of ſeeds; this he expreſſes by the word *Tetraſtœchon*, which Pliny ſuppoſing to be the ſame with the word *Tetragonon*, has tranſlated into *granum quadrangula figura*.

But this is by no means the ſenſe of the word which was uſed by the Greeks, to expreſs, that a thing had τέτταρας τάξεις, four rows, orders, or ſeries of ſeeds in it: Nor does it at all expreſs the ſeed's being ſquare, much leſs its being ſingle; for the original derivation of the word was from the term κατα ϛοιχὸν, uſed in dances. Theſe were compoſed of ſeveral ſeries of perſons, called ϛοιχοι, *ſtœchi*; and every ſtœchon conſiſted of ſeveral perſons, who all moved together.

It is plain from this, that *Tetraſtœchon* could not ſignify a fruit's having ſingle ſquare ſeeds, but muſt mean that it had four ſtœchi or orders of ſeeds in it; ſuch was the euonymus of the Greeks, which had a pod like that of ſeſamum to contain them; and had flowers of an offenſive ſmell, like that of corrupted blood. Theſe are all characters ſo very different from that of our euonymus or fuſanus, that it never would have been ſuppoſed by any perſon that they meant the ſame plant that we do by that name, had not Pliny led the world on to that opinion by his falſe and ſcarce intelligible tranſlation of the words of Theophraſtus.

TETRATONON, in muſic, the ſuperfluous fifth is ſometimes thus called, as containing four tones. *Broſſard*.

TETRAX, in zoology, the name of a bird of the gallinaceous kind, called by ſome authors *anas campeſtris*, or the field-duck; and by others the *canna*.

It is a very common bird in France, where it is called *canne patriere*, and ſeems indeed peculiar to that country; it is not called anas from any reſemblance it has to the duck, or any other water-fowl, in its make or ſtructure; but from its ſitting on the ground, juſt as the duck does on the water. It is of the ſize of a pheaſant, and has a beak like that of the common hen. It is taken with nets, as the partridge: It runs very ſwiftly, and, like the buſtard, has no hinder toes; and it ſeems properly a bird of that kind. Its belly is white, and its back is variegated with grey, red, and black. It feeds on vegetables, and on ſmall inſects. *Bellonius* de Avibus.

TETRASARIUS, a word uſed by ſome of the medical writers, to expreſs half an ounce.

TETREUMA, in botany, a name given by the people of Guinea to a species of shrub, very common among them, and used to cure whitlows. They dry the leaves, and reduce them to powder; and, moistening them with any liquor, apply them to the place. Petiver has called this *arbor guineensis laurustini facie*, from its great likeness to the common shrub, which we call the laurustine. The leaves are opake and stiff, and are an inch and a quarter broad, and two inches and a half long. These stand alternately on all sides the stalk, and are fixed on short pedicles. The flowers grow out of the bosoms of the leaves, and stand in clusters in the manner of those of the common laurustine. Phil. Transf. N°. 232.

TETTAR, in the manege, is an ulcer almost as broad as one's hand, that appears commonly upon a horse's croupe, sometimes on his head, and sometimes on his neck. It proceeds from bilious blood, that consumes and eats through the hide or skin, and causes such a violent itching, that it is a hard matter to keep the horse from scratching, and so enlarging and spreading the ulcer.

TETTIGES, τέττιγες, grasshoppers, in antiquity, a title the Athenians assumed to themselves. *Pott.* Archæol. Græc. l. 1. c. 1. T. 1. p. 2. See the article GEGENES.

TETTIGOMETRA, in natural history, a name by which the antients called the nymph of the Cicada, or *Tettyx*; and they named this nymph from which they frequently saw that fly hatched *Tettigometra*, which signifies the *mother of the cicada*.

It has been a great error in our dictionary writers, to call the *cicada* a grasshopper. It is a large four-winged fly, common in Italy, and other hot countries, and its noise is very troublesome there. This noise is made by means of certain organs placed in the belly. See HARVEST-*Fly* and CICADA.

This creature lays its eggs with a wonderful art in the dead branches of trees, and from these eggs are produced small animals like fleas, with six legs and a long trunk; these soon fall off from the tree, and, burying themselves in the earth, feed and enlarge themselves into a sort of hexapode worms; after this they pass into a state like that of the nymphs of our flies, or the chrysalis of butterflies; but they move and eat in this state.

They live in the form of the nymph more than a whole year, after which they crawl out of the earth, and climbing up the bodies of trees, there fasten themselves by their claws, till they are transformed into flies. In the time when they are in this nymph state they are found in great abundance buried about the roots of trees, often at two or three foot deep.

The antient Greeks used to dig them up from these places, and eat them; they were accounted a very good dish among them; and, according to Aristotle, were most valued, and esteemed the greatest delicacy, just before the time of their skin breaking to let out the fly. The antients also eat the cicada in its winged state, preferring the female when full of eggs, and the male at all other times. At present, though this creature is very common in most of the hot countries, and very troublesome by its continual noise; there is no account of their being eaten any where.

TETTIGONIA, in natural history, a word used by the antients to express the smaller species of *cicada*, with which they were acquainted. They called the larger *acheta*.

It is generally supposed that the *Tettigonia* was the same with our smallest kind, called by the French *cigalon*; but Mr. Reaumur observes, that as the antients knew two kinds of the *cicada*, we know three; and that our middle one seems to have been their *Tettigonia* or small *cicada*, and that they were not acquainted with our smallest kind, or cigalon, which is not larger than a hornet. See the articles HARVEST-*Fly*, and CIGALON.

TEUCHITES, in botany, a name used by some for the scænanth or schænanth, camel's hay.

It was originally used only as an epithet added to the name *Schænanth*, to signify the place from whence a peculiar kind of it was brought; but after-writers appropriated it as a name of the plant itself.

Dioscorides distinguishes the Arabian *Schænanth* from the Nabatæan; but this seems an unaccountable error, since Dioscorides one would think could not but know, that Nabatæa was only a region in Arabia. He afterwards makes the Babylonian the same with the Arabian, and says that it is called *Teuchites*. Pliny, on the other hand, gives the name *Teuchites* to the Nabatæan *Schænanth*.

Authors do not seem well to have explained the word. It is evidently an epithet given to the *Scænanth*, from the name of the place where it was brought, and probably it ought to be written *Teuochitis*. There is a city *Teuochis* in Ægypt near the borders of Arabia, and the geographers all mention a lake in the neighbourhood of this city; in this lake it is probable the *Scænanth* might grow; and being gathered there, and sold in the adjoining city of *Teuochis*, the purchasers might distinguish it with an epithet formed of the name of the place where they bought it. See the article SCHÆNANTH.

TEUCHTLACOT-*Zanhqui*, in zoology, a name by which the natives of some of the American nations call the rattle-snake. *Ray's* Syn. An. p. 291. See the article RATTLE-*Snake*.

TEUCRION, according to Pliny, a name given by some of the antient botanists to the *Chamædrys*, or germander.

This author supposes that plant and the *serrata* or *serratula*, to be the same in the accounts of some of the more early authors; but it does not appear, upon a strict enquiry, that they ever called any other plant than the common sawwort by the name *serrata*, though they called this plant by a great many other names beside that, as *betonica*, *cestrum*, &c.

TEUCRIUM, *Tree-germander*, in botany, the name of a genus of plants; the characters of which are these. The flower consists of one leaf, and is of the labiated kind; the stamina supplying the place of the upper lip; the lower lip is divided into five segments, the middle one being largest and hollowed like a spoon; the others standing over-against one another in the neck of the flower. The cup is bell-fashioned, and from it arises a pistil which is fixed in the manner of a nail to the hinder part of the flower, and is surrounded by four embryos, which afterwards become four roundish seeds, and ripen in the bell-shaped cup of the flower.

The species of *Teucrium*, enumerated by Mr. Tournefort, are these: 1. The shrubby *Teucrium*, with sinuated leaves, the Bœtic *Teucrium* of authors. 2. The broader-leaved Spanish *Teucrium*. 3. The American fox tail *Teucrium*. 4. The procumbent perennial *Teucrium*, with spear-pointed leaves. 5. The jagged-leaved annual procumbent *Teucrium* of Portugal. *Tourn.* Inst. p. 208.

TEUGA, in botany, the name given in the Hortus Malabaricus, to a genus of plants called by Linnæus and others, *coccus*. Hort. Mal. L. 1. 4. See the article COCCUS.

TEUTHOPHACE, a word used by the antients, to express a sort of food made of beet-roots and lentils, often prescribed as a good diet for the sick.

TEXT, TEXTURE, in chemistry, is used for any thing having a texture in a proper sense, or for an aggregate formed by admotion, composition, co-ordination, construction, whether fortuitous, or designed for some end, so that without such a texture the end could not be obtained; of which therefore, this texture must be considered as the true instrument.

In this sense living bodies have a texture, and may be strictly named *Texts*; and the more so, if they be sentient and have local motion; all which bodies, whether small or great, are formed of innumerable mixt and compound individual corpuscles. Vid. Observat. Halens. Tom. 4. Obs. 14. §. 8.

TEXT differs from *Aggregate*. See the article AGGREGATE.

TFUOI, in the Chinese manufactory of porcelaine, a word used to express a particular sort of varnish for that ware with violet colour and gold. The usual method of doing this at first, was by mixing gold with the common varnish, breaking the leaves very small, and then adding the common blue and the powder of calcined agate of a coarse kind, found in great plenty on the shores of their rivers. But they have since found, that the brown varnish called *Tsekin* succeeds greatly better, for when the blue is mixed with this, its brown colour is lost, and the gold lies on much better than it would any other way.

They had once a method of a varied varnish, which was very beautiful, but is much neglected now; this was the giving a vessel the brown varnish on the outside with a large portion of gold, and the common white varnish within. They also varied the degree of colour on the outside, by laying on more or less of the varnish; and gave this way a variety, even in the same colour. Observ. sur les Coutumes de l'Asie, p. 308.

THACAS, Θᾶκας, in antiquity, a general name given to the place or seat where the augurs made their observations. *Pott.* Archæol. Græc. T. 1. p. 322. See the article AUGUR.

THAIS, a name given by Ægineta, to a cosmetic cerate, intended to give a beautiful red to the face. Galen uses the same word to express a sort of bandage.

THALAMEGUS, among the antients, a ship of pleasure, or yacht used by princes. It was always provided with a good cabin, or bed-chamber. *Pitisc.* in voc.

Philopater king of Egypt had a very remarkable ship of this kind, for sailing in parade with his wife and children on the Nile. It is said to have been half a stadium, or 312 feet long; its breadth more than 30 cubits, and its height, with the pavilion erected on it, about 40 cubits. Its structure was likewise very singular, being broad-bottomed, and very wide above, especially towards the fore-part; and accommodated both with a double prow, and a double stern. On its decks were two long galleries of ivory, for walking in. *Hofm.* Lex Univ. in voc.

THALAMII, among the antients, those rowers who sat in the lowest part of the ship. *Pitisc.* in voc. See THALAMITÆ.

THALAMIUM, among the antients, a port-hole, through which the oars of the rowers in the bottom of the ship went. *Pitisc.* in voc.

THALAMITÆ, in the naval architecture of the antients, a term used to express those rowers in the Polyerete galleys, or those which contained several series of rowers, who sat on the *Thalamus* of the vessel, and made the lowest row. These moved their oars and hands under the seats of the row that sat

fat next above them. The word occurs chiefly in the defcription of the *Triremes*, or three-rowed galleys, in which the fecond row of the men were called *Zygitæ*, and the uppermoft *Thranitæ*. *Meibom.* de Trirem.

THALAMUS, in botany, a term ufed to exprefs that part of the flower in the capitated or flofculous flowered plants, where the embryo fruits of every feparate flofcule are lodged, and where afterwards the feeds are contained. This is the bottom of the cup, in the central part of which it adheres to the ftalk. *Tourn.* Inft. p. 438. See Tab. 1. of Botany, Clafs 1.

THALASSOMELI, the name of a medicine ufed as a purge among the antients. It was compofed of equal parts of honey, fea-water, and rain-water, expofed to the fun in the dog days, in a veffel pitched on the infide. It purged in the fame manner that fea-water alone would do, but only in a milder way.

THALIA, in botany, the name of a genus of plants, called by Plumier *cortufa*. The characters of which are thefe: The cup is a fpatha of an oval figure, terminating in a point, and compofed of only one valve. The flower is compofed of five petals, which are of an oblong ovated figure, and are hollowed and undulated at the margin; two of thefe, which are neareft the cup, are fmall and convoluted; the others are nearly equal in fize, and are ftrait and hollowed. The germen of the piftil is of an ovated figure, and the fruit is a berry of an oval figure, having only one cell, and within that a fingle bony feed which has two cells, in each of which is a thin kernel. *Plumier* 8. *Linnæi* Gen. Plant. p. 522.

THALICTRUM, *Meadow-rue*, in botany, the name of a genus of plants. The characters of which are thefe: The flower is of the rofaceous kind, being compofed of feveral petals arranged in a circular form. The piftil arifes from the center of the flower, and is furrounded by a vaft congeries of ftamina. This finally becomes a fruit compofed of feveral capfules gathered into a fort of head; thefe are fometimes alated, and fometimes plain, and each of them contains one oblong feed.

The fpecies of *Thalictrum*, enumerated by Mr. Tournefort, are thefe: 1. The larger *Thalictrum*, with angular or ftriated feed-veffels. 2. The larger *Thalictrum*, with fmooth feed-veffels. 3. The great yellow-flowered *Thalictrum*, with yellow ftamina, and bluifh-green leaves. 4. The columbine-leaved alpine *Thalictrum*, with purple ftamina. 5. The great columbine-leaved alpine *Thalictrum*, with white ftamina and green ftalks. 6. The leffer alpine columbine-leaved *Thalictrum*, with white ftamina and green ftalks. 7. The purple-ftalked columbine-leaved Canada-*Thalictrum*, with white ftamina. 8. The fmaller American *Thalictrum*. 9. The great yellow-flowered fweet-fcented *Thalictrum*. 10. The large-flowered afphodel-rooted fmall *Thalictrum*. 11. The early-flowering mountain-*Thalictrum*. 12. The leffer *Thalictrum*. 13. The narrow-leaved meadow-*Thalictrum*. 14. The little French *Thalictrum*, with thick fhining leaves. 15. The narroweft-leaved meadow-*Thalictrum*. 16. The fmall ftinking *Thalictrum*. 17. The little broad-leaved mountain-*Thalictrum*. 18. The little mountain-*Thalictrum*, with deep red fhining leaves. *Tourn.* Inft. p. 270.

THALLOPHORI, Θαλλοφοροι, in antiquity, the old men and women, who, in the proceffion of the feftival *Panathenæa*, carried olive boughs in their hands. *Potter*, Archæol. Græc. T. 1. p. 421.

THALYSIA, Θαλυσια, in antiquity, a facrifice offered by the hufbandmen after harveft. For the origin and ceremonies of which, fee *Potter*, Archæol. Græc. T. 1. p. 400.

THAMAR, a word ufed by the Arabian phyficians, to exprefs a date. Hence a pectoral decoction made with dates and other ingredients, was called *diathamyron*; and the word was afterwards corruptly written *dicameron*.

THAOCINUS *Color*, a term ufed in the Latin tranflations of the Arabian writers to exprefs what we call a blue purple, and the Latins *pavonaceus color*, peacock colour; which is alfo the literal fignification of the Arabian term.

The antient writers all tell us, that their *Indicum* when diluted, made the moft beautiful colour imaginable of that kind. This is one of many reafons for fuppofing the *Indicum* of the antients, and our *Indigo* to be the fame fubftance, becaufe this blue purple is the very colour of that drug when diluted.

THAPSIA, in botany, the name of a genus of plants; the characters of which are thefe. The flowers are difpofed in umbels, and are of the rofaceous kind, being compofed of feveral petals, difpofed in a circular order on a cup, which afterwards becomes a fruit compofed of two long ftriated feeds, furrounded with a foliaceous edge, and from both fides emarginated inwards. See Tab. 1. of Botany, Clafs 7.

The fpecies of *Thapfia*, enumerated by Mr. Tournefort, are thefe: 1. The largeft broad-leaved *Thapfia*. 2. The large hairy broad-leaved *Thapfia*. 3. The ftinking *Thapfia*, with libanotis-leaves. 4. The ftinking Portugal white-flowered *Thapfia*, with parfley leaves. 5. The narrower leaved Italian *Thapfia*, called *panax afclepium*, and Efculapius's all-heal. 6. The broadeft-feeded *Thapfia*, or giant-turbith. 7. The fhining alpine *Thapfia*, with thalictrum-leaves and white flowers. 8. The hairy thalictrum-leaved Portugal *Thapfia*. *Tourn.* Inft. p. 311.

The root of the *Thapfia* is ufed in medicine: There are two kinds of it, the white, and the black.

The white *Thapfia*, called alfo by fome grey turbith, is the root of a plant fomewhat refembling fennel. This is full of a milk-like juice, fo very fharp that it will bring off the fkin, if fuffered to touch the face. This root is feldom ufed under its own name, but is fometimes fold for the turbith root. They may be diftinguifhed however, by the turbith's being of a reddifh grey without, and of a whitifh grey within, and heavy and hard to break; on the contrary, white *Thapfia* is light, wrinkled, and of a filvery grey on the outfide, and fo hot and acrid to the tafte, that if new it will blifter the mouth.

The black *Thapfia* is of too dufky a colour to be ufed as an adulteration of turbith, and too hot and acrid to be prefcribed internally. *Lemery*'s Dict. des Drog.

Some of our druggifts receive the roots of this plant inftead of turbith, and fell it as fuch. It is happy for us, that it is not much in ufe. It purges very violently both upwards and downwards, and ought to be banifhed from among the number of medicinal fimples.

Befide the poifonous root known by the name *Thapfia*, the antients have defcribed three other vegetable fubftances under it. The Lycium-wood ufed at this time, as alfo of old in Crete, as a yellow dye: The *Scythica radix*, or liquorice; and the *luteola*, or dyers weed. The Greek *Thapfos* fignifies a pale dead yellow colour, and is applicable either to the fubftance or the juice or tincture of all thefe.

Paulus Ægineta and Alexander Trallian, in their catalogues of the things ufed to dye the hair yellow, mention the plant which they call *robia*, or *herba robia*, which they fay dyed every thing of a gold colour.

Democritus calls the fame plant *æcomenia*, and places it alfo among the herbs, ufed in tinging the hair. And fome of the more modern Greeks have called it *cymene*. It is ftill frequent in many parts of Greece, and is ufed there as well as here, to dye things yellow. Some have called it *carniola*; and Macer makes it the fame with the *ifatis* or woad; but very erroneoufly. Some have called it *rubia*; but thefe have carefully diftinguifhed it from the *rubiæ radix*, or madder, which dyes red. The old fcholiaft on Ægineta has alfo called this plant by the fame name with woad, and plainly fhews he thought the two names fynonymous, by rendering the *ifatis* of his author by the word *cymene*, which is plainly the fame plant with the carniola, that is the *luteola* of the Romans. See the article CYMENE.

THAPSOS, in the materia medica of the antients, a name given to a kind of wood of a pale yellow colour, ufed of old in dying linnen and woollen cloths.

It has by fome been fuppofed, that *Thapfos* and *Thapfia* were the fame plant; but there is no one circumftance in any of the accounts of authors, to favour fuch a conjecture. The *Thapfia* was always defcribed as a plant whofe root was poifonous; but the *Thapfos*, as a tree, whofe wood was not efteemed dangerous, and was ufed by the dyers; not the root, but the wood of the trunk and large branches. The natural colour of the wood being of a livid and dull yellow, it became an emblem of death; and the word *Thapfos* is ufed by fome of the Greek writers, as a name for the colour of dead corpfes.

The people of Crete at this time ufe the lycium-wood in dying a yellow colour, and it is probable that the *Thapfos* was this very tree. Diofcorides tells us, that the wood of this tree was alfo ufed at his time to tinge the hair yellow, which was a favourite colour with the Greeks. The lycium is of a colour fomewhat deeper than our box-wood, and parts with its ftain fo eafily that it feems very proper for fuch a purpofe. See the article THAPSIA, *fupra*.

THAPSUM, among the old Roman writers, a common name for the *verbafcum*, or mullein; but as there were many other plants, very different in their nature, yet whofe names refembled this; fuch as the *Thapfia*, or deadly carrot, and the *Thapfum*, or *geniftella tinctoria*; it was foon found neceffary to add fome other name, and it was then called *Thapfum barbatum*, or *barbaffum*.

The Greeks ufed the word *Thapfon* for a yellow colour, and called in general all yellow things by that name. Hence the great confufion that has arifen by calling the *Thapfia* root the liquorice root, the lycium wood, and the geniftella flowers, all by the common name *Thapfum*. The reafon of the geniftella being called *Thapfum*, was, that its flowers were yellow, and were ufed to colour the ladies hair; that being the favourite colour of thofe days. The flowers of mullein are yellow, and feem more fit for the colouring the hair, than thofe of the geniftella; their colour being more eafily feparated, and continuing on fo well that the glovers of many parts of England ufe them in the feafon for colouring their yellow gloves.

It is probable, that the ladies of old ufed this, as well as the geniftella, for this purpofe; and it might hence obtain the common name *Thapfum*. The other part of its diftinction, barbatum,

barbatum, feems owing to the leaves being fo covered with a woolly down that they look bearded. And when this word is written *barbaffum*, it may probably be given as the name of fome of thofe fpecies of mullein, which are not hairy, as our black or fage-leaved mullein, and be a corruption of the word *verbafcum*. This black mullein has no lefs title than the white or bearded kind, to the name *Thapfum*. Its flowers being of a yet finer yellow than thofe of that kind, and being as fit for the ufe of ftaining. The glovers of Hertfordfhire ufing this fpecies for their leather gloves.

THARGELIA, Θαργήλια, in antiquity, an Athenian feftival, in honour of the fun, and his attendants the hours; or, as others think, of the Delian Apollo and Diana. For an account of the ceremonies of this folemnity, fee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 400. feq.

THARGELION, Θαργηλιών, in chronology, the eleventh month of the Athenian year. It contained thirty days, and anfwered to the latter part of our April, and the beginning of May. See the article MONTH.

It took its name from the feftival *Thargelia*, kept in it. See the article THARGELIA, *fupra*.

THASIUM *Marmor*, in the writings of the antients, a name given to a fpecies of marble, ufed in building. It had its name from the ifland Thafus, one of the Cyclades, where it was dug; it was of a dufky greyifh white, and feemed to be compofed of the fame matter with the common white marbles with greyifh veins; only that the matter of the veins here did not run into thofe determinate parcels, but were blended among the whole mafs.

THAUGHTS, or THOUGHTS, in a boat, are the benches on which the rowers fit to row.

THEATRIC *Bandages*, a term ufed by Hippocrates, to exprefs the parade of furgery in applying bandages for fhew, when there was no real ufe in them. All fuch bandages he called *Theatric*, proper only to be looked at.

THEBANUS *Ophites*, in natural hiftory, a name given by fome of the antients, to that fpecies of the *Ophites*, or ferpentine marble, more commonly called *Ophites niger*, the black ferpentine. See the article OPHITES.

THEDO, in ichthyology, a name given by Figulus and others, to the trout. See the article TRUTTA.

THEIOCRUS, in the materia medica of the antients, a name given by fome to the *Melanteria*, a mineral fubftance of a vitriolic nature, and of a yellow colour, but turning black on touching common water.

This name *Theiocrus* fignifies only fulphur-coloured, and was at firft ufed with the name of vitriol, as expreffive of the difference of this kind from others; but in time it became common to ufe it alone.

THELE, a word ufed by fome to exprefs the nipple, and by others for the whole breaft.

THELIGONIUM, in botany, the name of a genus of plants, called by the common authors of botany, *cynocrambe*. The characters are thefe: The male and female flowers are produced in the fame plant. In the male flower the cup is compofed of one leaf, of a turbinated form, lightly divided into two fegments with the jaggs turning downward. There are no petals. The ftamina are numerous, being ufually twelve at leaft; they ftand erect, and are of the length of the cup; and the antheræ are fingle. The female flower has an extremely fmall one-leaved cup, which is bifid, and its fegments gape open. There are no petals. The piftil has a globofe germen; the ftyle is fhort, and the ftigma obtufe. The fruit is a globofe capfule, of a coriaceous texture, having only one cell, and containing only one globofe feed. *Linnæi* Gen. Plant. p. 406. *Tourn.* Inft. p. 485.

THEMIS, in aftronomy, a name given by fome to the third fatellite of Jupiter. *Lowth.* Abr. Philof. Tranf. Vol. 1. p. 408.

THENAR, (*Cycl.*) a very thick and flefhy mufcle, in fome meafure pyriform, lying on the firft phalanx of the thumb toward the palm of the hand, the large eminence in which is chiefly formed by it. It is fixed to the bone which fupports the thumb, and to the neighbouring part of the great internal annular or tranfverfe ligament of the carpus. It is in fome meafure bicipital; two diftinct portions anfwering to the two infertions. As it runs along the firft phalanx, thefe two portions unite, and diminifhing in thicknefs, are both inferted by one tendon in the lateral internal part of the head of the firft phalanx, in the lateral part of the bafis of the fecond, and in the lateral ligament of that joint. The void fpace between the two portions of this mufcle gives paffage to the tendon of the *flexor pollicis longus*. That portion which lies neareft the hollow of the hand is largeft; and its tendinous extremity is inferted in the firft fefamoide bone, fituated at the bafis of the fecond phalanx. *Winflow's* Anat. p. 196.

THENAR *Pedis*, a mufcle made up of feveral portions, and lying on the inner edge of the fole of the foot. It is fixed by three or four flefhy fafciculi to the lower and inner part of the os calcis, fcaphoides, and cruciforme majus, and a little in the annular ligament under the inner ankle, which belongs to the tendon of the flexor longus. From all thefe infertions the fafciculi approach each other, as they advance under the firft bone of the metatarfus, and are fixed in the internal fefamoide bone, and infide of the firft phalanx near its bafis; and there is another fafciculus fixed by one end of the os fcaphoides, and cuneiforme majus; and by the other to the external fefamoide bone, and outfide of the firft phalanx of the great toe. *Winflow's* Anat. p. 222.

THENSA, among the Romans, a veil or canopy, ufed in the chariots at games; and likewife to cover a feat of ftate. *Pitifc.* in voc.

Thenfæ could not be granted to any but by the exprefs allowance of the fenate. Hift. Acad. Infcript. Vol. 1. p. 359.

THEOBROMA, in botany, the name of a genus of vegetables, including the cacao and the guazuma of Plumier. The characters are thefe: The cup is a three-leaved perianthium reflex and open, and is compofed of oval, concave, and deciduous leaves. The corolla is compofed of five petals, erect, open, concavely galeated, and terminated by a bifid briftle. The nectarium is campanulated, and confifts of five petals; it is fmaller than the flower, and confifts of five connected parts. The ftamina are five-pointed filaments of the length of the nectarium; each has its top divided into five fegments, and carrying five apices or antheræ. The germen of the piftil is oval, the ftyle is pointed, and is of the length of the nectarium, and the ftigma is fimple. The fruit is a woody fubftance, ribbed in five places on the furface, and divided into five lodgments of feeds within. The feeds are numerous, flefhy, and of an oval figure. There is fome difference in the fruit of the feveral fpecies of thefe trees; the cacao having a long fruit, tapering at each end, and the guazuma a globular one, full of tubercles, and perforated in the manner of a fieve, but divided into five lodgments within. *Linnæi* Gen. Plant. p. 367. *Plumier*, Gen. 18. *Tourn.* Inft. p. 444.

THEODOLITE (*Cycl.*)—This inftrument is now commonly made ufe of by furveyors. One of the beft of the kind feems to be Mr. Sifon's lateft improved *Theodolite*; a defcription of which may be found in Mr. *Gardner's Practical Surveying improved*; from whence it has been inferted in a late treatife of practical geometry, publifhed at Edinburgh 1745, in 8°. under the care, as it is commonly thought, of the late celebrated Mr. M^cLaurin.

In this inftrument the three ftaves, by brafs ferrils at top, fcrew into bell metal joints, moveable between brafs pillars, fixed in a ftrong brafs plate; in which, round the center is fixed a focket with a ball moveable in it, and upon which the four fcrews prefs that fet the limb horizontal. Next above is fuch another plate, through which the faid fcrews pafs, and on which round the center is fixed a fruftum of a cone of bell-metal, whofe axis, being connected with the center of the ball, is always perpendicular to the limb, by means of a conical brafs ferril fitted to it, whereon is fixed the compafs-box, and on it the limb, which is a ftrong bell-metal ring, whereon are moveable three brafs indexes, in whofe plate are fixed four brafs pillars, that joining at top, hold the center-pin of the bell-metal double fextant, whofe double index is fixed in the center of the fame plate. Within the double fextant is fixed the fpirit level, and over it the telefcope.

The compafs-box is graved with two diamonds for north and fouth, and with 20 degrees on both fides of each, that the needle may be fet to the variation, and its error alfo known.

The limb has two flower-de-luces againft the diamonds in the box, and is curioufly divided into whole degrees, and numbered to the left hand at every 10° to twice 180°, having three indexes (with Nonius's divifions on each for the decimals of a degree) that are moved by a pinion fixed below one of them without moving the limb, and in another is a fcrew and fpring under, to fix it to any part of the limb: It has alfo divifions numbered for taking the quarter girt in round timber; to which a fhorter index is ufed, having Nonius's divifions for the decimals of an inch; but an abatement muft be made for the bark, if not taken off.

The double fextant is divided on one fide from under its center (when the fpirit-tube and telefcope are level) to above 60 degrees each way, and numbered at 10, 20, &c. And the double index (through which it is moveable) fhews on the fame fide the degree and decimal of any altitude or depreffion to that extent, by Nonius's divifions; on the other fide are divifions numbered for taking the upright height of timber, &c. in feet, when diftant ten feet, which at 20 muft be doubled, and at 30 trebled; and alfo the quantities for reducing hypothenufal lines to horizontal: It is moveable by a pinion fixed in the double index. See the article SURVEYING.

The telefcope is a little fhorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and fhew a diftinct object as perfect, as moft of treble its length; in its focus are very fine crofs wires, whofe interfection is in the plane of the double fextant, and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; fo that whenever the limb is fet horizontal (which is readily done by making the fpirit tube level over two fcrews, and the like over the other two) the double fextant and telefcope are moveable in a vertical plane, and then every angle taken on the limb (though the telefcope be never fo much elevated or depreffed) will be an angle in the plane of the horizon, and this is abfolutely neceffary in plotting

ting an horizontal plane. Treat. Pract. Geom. p. 75. seq.

THEOGAMIA, Θεογαμια, in antiquity, a Sicilian festival in honour of Proserpine, which seems to have been instituted in memory of her marriage with Pluto. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 402.

THEOMANTIA, Θεομαντεια, in antiquity, divination by the supposed inspiration of some deity. For a particular account of which, see *Potter*, Archæol. Græc. l. 2. c. 12. T. 1. p. 298 seq.

THEOPHANIA, Θεοφανεια, in antiquity, a festival observed by the Delphians upon the day whereon Apollo first manifested himself to them. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 402.

THEOPHRASTA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: The cup is a small perianthium, lightly divided into five obtuse segments, and remaining when the flower is fallen. The flower consists of a single petal, in form of a bell, slightly divided into five obtuse segments. The stamina are five tapering filaments, shorter than the flower. The antheræ are simple. The germen of the pistillum is of an oval figure. The style is tapering, and shorter than the flower. The stigma is acute. The fruit is a very large globose capsule, containing only one cell. The seeds are numerous and roundish, and are affixed to every part of their receptacle, which is loose. *Linnæi* Gen. Plant. p. 66.

THEOPHRASTICS, a name given to the followers of Paracelsus, from his name Theophrastus.

THEOPNEUSTÆ, Θεοπνευσται, an epithet given to enthusiastical diviners. *Pott.* T. 1. p. 302.

THEOPROPIA, Θεοπροπια, a designation given to oracles. See the article ORACLE, *Cycl.*

THEORI, Θεωροι, in antiquity, an appellation given to those Athenians who performed the solemnity called *Theoria*. See the next article.

THEORIA, Θεωρια, in antiquity, a solemn annual voyage to Apollo's temple in the island Delos, performed by the Athenians always in the same ship in which Theseus went. For the particularities of this naval procession, see *Potter*, Archæol. Græc. l. 2. c. 9. T. 1 p. 284. seq.

THEORY (*Cycl.*)—THEORY *of Chemistry*. Under the *Theory* of this art are to be laid down all the general truths which the particular experiments of chemists have hitherto demonstrated. These are, on this occasion, to be taken for granted, and the whole body of such truths makes the universal *Theory* of chemistry, for chemistry is no science formed *a priori*; 'tis no production of the human mind, or raised by reasoning, but collected *a posteriori* from experiments; it took its rise from various operations casually made, and observing those that had one and the same uniform tendency, without any expectation of what followed; and was only reduced into an art, by collecting and comparing the effects of such uncertain experiments, and noting the tendency thereof: So far then as a number of experiments agree to establish any unquestionable truth; so far they may be considered as constituting the *Theory* of chemistry. Such a *Theory* is necessary to be premised to every art; and something equivalent to this is practised by every artisan, in teaching his disciple how to proceed orderly in the exercise of his art; and accordingly it would be impossible to teach the practice of chemistry to advantage, without having first given some such *Theory*. Thus it would be to little purpose, to give a novice a parcel of rosemary, for instance, and bid him, without any addition, distil a water from it, which should contain the natural taste and odour of the plant; unless he knew before-hand this general truth, that plants, exposed to a gentle heat, like that of the summer's sun, do exhale their most subtle and volatile parts, which, being collected and condensed by means of proper vessels, appear in form of water, and are the thing required. *Shaw's* new Meth. of Chem. p. 3.

In the forming such a *Theory* of chemistry, a direct use may indeed be made of the demonstrations in physics, as particularly in mechanics, hydrostatics, and hydraulics; since the properties common to all bodies, and what farther affections certainly flow therefrom, have their place in chemistry. One cannot, however, be too reserved in this use, since those singular properties found in some bodies, will, if applied to others, falsify the mechanical demonstrations, which might hold true every where else. Thus Galilæo has fully demonstrated the law, by which an heavy body, let fall from on high, descends in a spiral or elliptic line, with a certain degree of acceleration to a point of the earth, perpendicular to the horizon of the point from whence it was first let fall; but if a loadstone be thus let fall, and in the course of its descent enter the sphere of activity of another load-stone, the demonstration will not hold. So what Archimedes has shewn, concerning bodies equiponderant in water, holds infallibly true, if considered only in common cases, but proves false in the instance of gold; which, tho' it sink in other fluids, is suspended and dissolved in light aqua regia. *Boerhaave*, Chem. p. 3.

Due regard being had to this rule, the discoveries of naturalists and mathematicians will always be advantageous, never injurious to the art of chemistry.

Chemistry, as now conceived, is an assemblage of very different parts, which antiently subsisted separate, or at least had a subsistence prior to each other, as the preparing of metals for human uses, the attempts of transmuting the baser metals into gold, the preparing of medicines, &c. If we are to trace the antiquity of chemistry, as an art that teaches to convert other metals into gold, or to procure an universal remedy for all diseases, the research will not carry us far back; but as it relates to the discovery of metals in the mine, and the digging, separating and purifying them, it challenges even the highest antiquity.

The art of metals is, no doubt, of very early standing. To find, procure, fuse, refine, and render malleable, and apply metal to use, is even of antediluvian origin, and was attributed by the antients to their gods. Moses, the oldest author extant, in his genealogy of the patriarchs, relates that Tubal Cain, the eighth from Adam, was the instructor of every artificer in brass and iron, to prepare the instruments and utensils of life; and 'tis apparent nothing of this could be effected without the knowledge of metallurgy. This account given us by Moses, is surprisingly seconded by prophane history and fables; for Diodorus Siculus, who lived in the time of Cæsar, when Ægypt was become a Roman province, had a fair opportunity of searching into the antiquities of the Ægyptians; and he relates, as the result of his enquiry, a very antient tradition of one Hephaistos, whom that people hold the first inventor of all arts and operations about metals, and every thing else that undergoes the fire; together with their uses; which art he delivered down to posterity, so far as it might be of service to mankind. This Hephaistos of the Ægyptians and Greeks, is the same with the Mulciber and Vulcan of the Latins, to whom the same art or invention is ascribed; and the Vulcan of the Latins we generally suppose to have been the Tubal Cain of the Hebrews, here mentioned by Moses as the inventor of the said art.

It appears from Homer, Hesiod, Orpheus, and all the most antient writers, that Vulcan had the art of working brass and iron; and that, living under mount Ætna, he was employed in forging arms for the gods and heroes. As Diodorus Siculus relates the story, he was the son of Jupiter and Juno, and the first king of Ægypt, and that he was afterwards preferred to be a god, for having invented fire, and taught men the use of it. The Ægyptians, as the same Diodorus observes, adored their god Vulcan as the inventor of the whole art and application of metals; so that the account of Moses and Diodorus perfectly agree, and prove the chemistry of metals almost coeval with mankind. *Shaw's* Chem. p. 10.

THEOXENIA, Θεοξενια, in antiquity, a festival in honour of all the gods, and celebrated in many cities of Greece, but especially at Athens. *Potter*, T. 1. p. 402.

THEOXINI *Malagma*, the name of a sort of cataplasm, good against pains of the feet.

THERAPIDION, in botany, a name given by some authors to the common oister-green, or sea-laver, a plant of the tremella kind. See the article TREMELLA.

THERMASMA, a word used by some of the antients to express any thing that warms the body, and by others particularly for a warm fomentation, prescribed by Hippocrates for removing pains in the side, and giving ease in pleurisies.

THERMOMETER (*Cycl.*)—Dr. Martin has made useful remarks on the construction and graduation of *Thermometers*, and has reduced the most remarkable of these instruments, which have been employed in different parts of Europe, for observing the changes in our atmosphere, to one general standard, so as to enable us to compare the several observations together. See his Physical and Medical Essays.

THERMOPOLIUM, a name for a sort of public houses among the antients, in which hot liquors were sold, in the manner of our coffee-houses.

THESEIA, Θησεια, in antiquity, an Athenian festival, in honour of Theseus, and celebrated on the eighth day of every month. For the ceremonies of this solemnity see *Potter*, Archæol. Græc. T. 1. p. 404.

THESIS, (*Cycl.*) in music, denotes the fall of the hand in beating time. The Latin writers call it *depressio*. *Brossard*.

THESMOPHORIA, Θεσμοφορια, in antiquity, a festival in honour of Ceres, which was celebrated by many cities of Greece; but especially the Athenians observed it with great devotion and pomp. For the ceremonies of this solemnity, see *Potter*, Archæol. Græc. T. 1. p. 403. seq.

THESMOTHETÆ, Θεσμοθεται, in antiquity, an appellation given to six of the nine Athenian *archons*; the first and chief of the nine was called, by way of eminence, *archon*; the second in dignity was called *basileus*, the third *polemarchus*, and the other six *Thesmothetæ*; for an account of whose power and jurisdiction, see *Potter*, Archæol. Græc. T. 1. p. 77.

THESPHATA, Θεσφατα, in antiquity, an appellation given to oracles. See ORACLE, *Cycl.*

THESPIANA, the name of an antidote, intended for internal abscesses.

THETA, Θ, among the antients, one of the Greek letters. It was used as a mark on the ballots of judges, by which they condemned the person to death, it being the first letter of the word Θανατος, death. Whence it had the epithet of *niger* and *infelix*, thus:

O multum ante alias infelix litera Theta.

 THETES,

THETES, Θῆτες, in antiquity, the loweſt claſs of people at Athens. Ariſtides repealed Solon's law, by which the *Thetes* were made incapable of bearing any office in the government. *Potter*, Archæol. l. 1. c. 4. p. 16.

THEVET, a name of one of the Hebrew months, anſwering to our December moon. See the article TEBET.

THEXIS, a word uſed by the old medical writers, ſometimes for wounds made by puncture with ſmall inſtruments, and ſometimes for the operation of the future, or the ſowing together the lips of a wound, to make it heal with a leſs ſcar.

THIGH (*Cycl.*)—THIGH-*Bone*. We have an account in the Philoſophical Tranſactions of a large piece of a young man's *Thigh-bone* being taken out, and the place ſo well ſupplied by a callus, that he walked ſtrait. See N°. 461. Sect. 2.

Fractured THIGH-*Bone*. The *Thigh-bone*, though the largeſt and ſtouteſt in the whole body, is yet frequently broken, both near its middle, and towards its ends or articulations; but more particularly near that part uſually called its neck, near its articulation with the hip-bone; and when this is the caſe, it is very difficult to ſet it, and retain it in its place. When the bone is broke in two places at once, which ſometimes happens, the danger is yet much greater; and if the patient, in this caſe, eſcapes death, which he ſeldom does, he is commonly lame, ever afterwards.

Sometimes this bone is broken tranſverſely, ſometimes obliquely, and at other times the ends ſlip a great way over one another, which makes it a very bad caſe; for the muſcles of this part being very robuſt, and ſtrongly contracted, draw the lower end of the bone with a conſiderable force upwards, ſo as to make it require great ſtrength to extend and replace it.

The oblique fracture of this bone more frequently ſlips out of its place again than the tranſverſe, and generally leaves the *Thigh* ſomewhat ſhorter than the other, notwithſtanding all the caution the ſurgeon can uſe in the ſetting it. It is therefore neceſſary, in theſe caſes, beſide the means that are common to all the fractures, to uſe a more ſtrict and tight bandage in this than in the tranſverſe fracture, to prevent the bones from being eaſily removed. When a fracture of the *Thigh-bone* happens near its middle, or towards it lower head, it is to be extended and replaced with the hands like other fractures, except that the extending force required is very great; and where the hands of a ſtrong aſſiſtant are not enough, ſlings, napkins, or linnen bandages, are to be bound round each head of the *Thigh*, whereby the fractured bone may be extended both ways, by the ſtrength of three or four perſons at once, while the ſurgeon cautiouſly reduces the fracture with his hands, and ſecures it with a proper bandage and dreſſing; there are ſometimes caſes where the joint ſtrength of three or four men, applid in this manner, are not ſufficient to make the neceſſary extenſion; in which caſe the ſurgeon is obliged to have recourſe to ropes and pullies, by means of which one man will pull more forcibly and equally than ſeveral can without them. But caſes that require this treatment are not common.

When the neck of the *Thigh-bone* is fractured, to which, from its oblique or tranſverſe direction, and ſpongy or brittle ſubſtance, it is very ſubject; it makes a fracture not only very difficult to reduce, but ſuch a one alſo as can ſeldom be cured without leaving the limb ſhorter than it was before. The reaſons of which are, that the fragments cannot but with great difficulty be preſſed into their right places, by reaſon of the great thickneſs and ſtrength of the muſcles which cover them; and that it ſeldom happens that the bones can be retained in their natural poſition, after they have been ever ſo well reduced; becauſe the muſcles which paſs over and are inſerted below the neck of this bone, draw its lower part upwards; and both theſe accidents happen the more naturally and eaſily, becauſe of the oblique poſition of the neck of this bone, which is inſerted into its head in a direction not perpendicular, nor parallel, but as it were ſloping on one ſide; ſo that it is no wonder that lameneſs, and other bad accidents, are the conſequences of this ſort of fracture.

To all theſe reaſons we may alſo add, that it is very difficult to diſcover when the neck of the *Thigh-bone* is fractured, this caſe being uſually taken for the head of the bone being ſlipped out of its ſocket or acetabulum; and this indeed, till of late, has been almoſt a general error. When we can think the external force to have been ſtrong enough to have produced a fracture, when the patient cannot bear any ſtreſs upon the limb, by ſetting his foot on the ground, when very acute pains are felt about the articulation itſelf; and when we find the affected limb ſhorter than the ſound one, it being an eaſy matter to turn the foot almoſt round from one ſide to the other, and any cracking or grating of the bones be perceived in that motion, me may reaſonably ſuppoſe the neck of the *Thigh-bone* is fractured; the limb muſt then be extended very gently and gradually, till it be brought to the ſame length with the ſound one; this may be eaſily done, either by means of a napkin, or the hands of an aſſiſtant in moſt caſes, in ſuch a manner, that the ſurgeon may be able to rejoin, in ſome meaſure, if not perfectly, the neck of the *Thigh-bone* with its head, ſtill firmly remaining in its ſocket: And though a ſhortneſs of the limb, or lameneſs, is generally left behind after this fracture; yet becauſe there are ſome cured without thoſe miſfortunes, it is always beſt to uſe, for that end, ſo ſtrict or tight a bandage, that it may retain the neck and head of the bone together, ſo that they may be in a way of uniting evenly. The bandage called *ſpica inguinalis* is the moſt convenient for this purpoſe, and a large and broad napkin, or other linnen cloth, is, with this, placed between the *Thighs*, to keep the body of it from ſubſiding; and laſtly, ligatures are put about the knee and ancle, by which the foot is faſtened to the lower part of the bed, to prevent the limb from being contracted upwards.

If the fracture of the *Thigh-bone* be accompanied with a wound, it makes the caſe very difficult and dangerous. And if theſe accidents happen to be inflicted on the neighbouring joint, death is generally the conſequence, more eſpecially when any of the large blood-veſſels are alſo wounded, which will be readily enough known by the hæmorrhage. In theſe fractures, with a wound, the eighteen-headed bandage is to be uſed for the dreſſing; and if the wound be much contuſed, ſo that extravaſated blood be lodged under the ſkin, and about its interſtices, it is to be carefully opened by ſeveral inciſions, of a ſufficient depth, that the extravaſated blood, which would in a ſhort time putrify, may be diſcharged. The injured parts are to be afterwards waſhed with lime-water, mixed with a fourth part of ſpirit of wine camphorated, till the contuſed parts are digeſted.

When this kind of fracture is accompanied with no very violent loſs of blood, nor the bone near, the proper dreſſing is dry lint folded up, with which the wound is to be filled. If the flux be greater, rectified ſpirit of wine, or other aſtringent liquors are to be uſed; but if the hæmorrhage be very violent, from an artery, the tourniquet is to be uſed, and the veſſel ſecured by a ligature. After the blood is ſtopped, and the wound cleanſed, the fragments of the bone are to be replaced, and the limb carefully bound up with compreſſes, ſplints, and the eighteen-headed bandage, and defended by a caſe of ſtraw. But if the fracture is attended with a violent hæmorrhage, and great ſplintering of the bone, from gun-ſhot wounds, ſo as to indicate the great crural artery to be wounded, the beſt method is to amputate the *Thigh*, and tie up the artery in time; for the crural artery is ſo large, that it ſeldom grows together; and if it does, the lower parts are ſoon ſeized with a gangrene. *Heiſter*, 129.

We have the deſcription and draught of a machine for reducing fractures of the *Thigh-bone*, by Mr. Ettrick, in the Phil. Tranſ. N°. 459. Sect 4.

Luxated THIGH. It has been formerly imagined, that the head of the *Thigh-bone* being diſplaced out of its acetabulum, was a very common caſe; but more knowledge in anatomy and ſurgery have convinced us now, that this accident is very rare. The reaſon it was before ſuppoſed common, was, that a fracture of the neck of the *Thigh-bone* was generally miſtaken for this luxation.

It will eaſily be conceived, that this is the true ſtate of the caſe, and that a real diſlocation of the *Thigh-bone* is very rare, if we conſider how very deep the ſinus or acetabulum is, into which the head of this bone is received, with what a broad concave cartilage the head of this bone is covered, how extremely ſtrong the ligaments are with which it is faſtened, how greatly it is defended with thick and ſtrong muſcles, and at the ſame time reflect how very weak and brittle the neck of the *Thigh-bone* is, in compariſon of any other part thereof; and from all theſe conſiderations, how vaſtly more eaſy it muſt be for the ſame force to break the bone off juſt under its head, than to diſplace it out of its ſocket. And, indeed, when luxations of the *Thigh-bone* do happen, it is much more frequently from internal than from external cauſes. For phyſicians have obſerved, that the ligaments of the *Thigh-bone*, though naturally of extreme ſtrength, may be, by various cauſes, and particularly by a flux of humours, ſo relaxed and weakened as to let the head of that bone ſlip ſpontaneouſly out of its acetabulum or ſocket; ſo that the *Thigh*, though not eaſily luxated by external violence, may eaſily happen to be ſo without any external violence, and while the patient lies in his bed. This is an accident, however, that happens much more rarely to adults than to infants.

Whenever the head of the *Thigh-bone* is thruſt out, it is almoſt always wholly diſplaced; ſo as to make a perfect luxation; the exact roundneſs of this head, with the great ſtrength of the circumjacent muſcles, and the narrowneſs of the ſides of the acetabulum, will not admit the bone to be partially diſlocated or thruſt out of its place a little way only; for as ſoon as the head of the bone is thruſt up to the edge of the acetabulum, it muſt unavoidably either turn quite out, or fall back again into its right place.

The thigh is found to be capable of luxation four ways, upward and downward, and backward and forward; but it is moſt frequently diſlocated downward and inward, toward the large foramen in the os pubis. For beſide, that the cartilaginous defence, on the lower part of the acetabulum, is not ſo high as in the reſt, the ligamentum rotundum is ever found to give way more readily in that part than in any other; and laſtly, the adjacent muſcles are found to be weakeſt in their reſiſtance on this part. And there is, beſide all theſe, a certain eminence in this edge of the acetabulum, which prevents the head of the bone from falling back again eaſily into its right place, when

when once it is got this way out of it. But if the head of this bone be diſplaced outwards, it generally ſlips upwards at the ſame time, it being ſcarce poſſible but that the very ſtrong muſcles of the *Thigh* muſt then draw the bone upwards; and there is no eminence in this edge of the acetabulum to reſiſt the head of the bone in that paſſage.

When the *Thigh* is diſlocated forwards and downwards, which is what moſt uſually is the caſe, the leg hangs ſtradling outward, and is longer than the other; the knee and foot alſo both turn outwards, and the head of the bone itſelf will be felt near the lower part of the inguen and os pubis. Sometimes there is a ſuppreſſion of urine in this caſe, which is occaſioned by ſome nerve which communicates with the bladder being violently compreſſed; in the buttock there alſo may be perceived a cavity from the trochanter major, and the reſt of the bones being diſplaced; and if the *Thigh-bone* be not timely reduced into its acetabulum, the whole limb withers ſoon afterwards. The patient, for this reaſon, can bear little or no ſtreſs upon that limb, but muſt always incline and throw the weight of his body upon the other; when he moves forward, he muſt move that limb in form of a ſemicircle, and ſupport his body by crutches under the arms; though there are not wanting particular caſes, where the head of the luxated *Thigh-bone* has grown ſo firmly to the adjacent parts, without the acetabulum, as to become, in proceſs of time, ſo ſtrong as to ſupport the body without ſticks, though the perſon could not, in any of the caſes that have been known of this kind, walk without halting.

If the *Thigh-bone* be diſplaced backward, it is uſually drawn upward alſo, as before obſerved, at the ſame time; hence there will be perceived, in this caſe, a cavity behind the inguen, and a tumour upon the buttock, becauſe the head, and trochanter of this bone, will be placed there. The tumour on the buttock being thruſt upward, the limb will become ſhorter than before, and the foot will be inclined to turn inwards. The heel will not touch the ground, but the perſon ſeem to ſtand upon his toes; and laſtly, the luxated limb will be much more eaſily bent than extended.

It is extremely rare that the *Thigh* is luxated forward or backward, without being alſo drawn upward or downward; but if it ſhould ſo happen, it will yet evidently be diſcovered by the rules before given, and by conſidering the nature of the articulation of the bone: As it is, however, at beſt very difficult to diſcover when the *Thigh-bone* is diſlocated, and when it is fractured, either by feeling or inſpecting, becauſe of the great thickneſs of the muſcles and integuments, it is therefore a matter of ſome conſequence to propoſe the ſigns by which one of theſe caſes may be known from the other. There is reaſon to judge the *Thigh-bone* to be luxated, when we find the ligaments of the bone have been relaxed by ſome preceding congeſtion of humours, when no external violence has been exerted upon it, when neither violent pain, tumours, nor inflammation follow; and laſtly, when the whole limb may be bent, and turned about at the acetabulum, without the ſurgeon's diſcovering any grating or cruſhing of the bones; and the contrary of theſe ſigns, which are what uſually take place, in what have been uſed to be called luxations of this bone, are very ſtrong indications of a fracture.

When the bone is found to be really diſlocated, it is to be reduced in a method agreeable to the nature and direction of the diſlocation. When it is diſplaced forward and downward, the patient is to be laid flat upon his back on a table; then a linnen napkin, or ſtrong ſling, is to be made faſt about the groin, over the part affected, ſo that one end of the ſling may come over the belly, and the other over the nates and back, to be both tied together in a knot upon the ſpine of the os ileum, and afterwards either faſtened to a hook fixed in ſome poſt, or held firm by ſome aſſiſtance: In like manner at the bottom of the *Thigh*, a little above the knee, there muſt be faſtened another napkin or ſling, or elſe the girt of Hildanus, with a compreſs between it and the *Thigh*; both theſe ſlings being drawn tight, the *Thigh* is to be extended, but that not vehemently; but only ſo much as is ſufficient to draw the bone out of its ſinus, that it may be replaced into its proper acetabulum by the ſurgeon's hands; to this purpoſe the ſurgeon is, with one hand, to preſs the head of the *Thigh-bone* outward, while the other conducts the knee inward. Or the reduction may be made by napkins faſtened about the *Thigh* near its extremities, in the manner of ſlings, and the limb extended that way, the knee being at the ſame time preſſed inward by the hands.

If theſe methods are not ſufficient, it will be neceſſary to have recourſe to the polyſpaſton or pulley, well known to the ſurgeons on theſe occaſions. This is to be the method of reduction of the *Thigh-bone* when it is diſlocated forward; but when it is found to be luxated backward, the patient is to be placed flat on a table, with his face downward; the *Thigh* is then to be extended more ſtrongly than in the former caſe, and the reduction is then to be performed by the ſurgeon's hand, an aſſiſtant all the while turning the limb ſomewhat inwards, and by this method the head of the *Thigh-bone* generally ſlips very readily from this ſort of diſlocation into its proper place. The limb is then to be ſecured with proper bandages, and the patient to be kept to his bed for three or four weeks. *Heiſter*, Surg. p. 167.

Saltzmannus relates an inſtance of a luxation of the *Thigh-bone*, without any fracture of its neck, and confirms what Ruyſch had obſerved of the epiphyſis of the os femoris, being as it were annihilated, or at leaſt changed ſo, as it could not be obſerved, when ſought after in one who had it broken.

THIGH, in the manege. The effect of the horſeman's *Thigh* is one of the aids that ſerves to make a horſe work vigorouſly. See the article AID.

Fore-thigh, or *arm* of a horſe, is that part of the fore-leg that runs between the ſhoulder and the knee: Though the *fore-Thigh* does not bend or bow, yet we commonly ſay, a horſe goes fine, that bends well the *fore-Thigh*, importing thereby, that he bends well his leg.

THILYPTERIS, in botany, a term uſed by Dillenius to expreſs the common female fern or brakes. *Dill.* Cat. 174.

THIMHIO, in the materia medica, a name uſed by ſome authors for a peculiar ſort of lignum aloes, which is blackiſh and very heavy, and extremely ſweet. *Camell.* Syll. p. 87.

THIN, in the materia medica, a name given by the Arabian writers to earth of any kind.

Thus the bole armenic of Galen is called by Aviſenna *thin armeni*; and hence the word *muthin*, an adjective ſignifying earthy, or approaching to the nature of earth; a term applied to many medicines of this kind.

THINA, in botany, a name by which ſome authors have called the larix or larch tree. *Ger.* Emac. Ind. 2.

THIRD (*Cycl.*)—THIRD *Major*. The logarithm, or meaſure [a] of the octave $\frac{2}{1}$ being 1 . 000000, the meaſure of the greater *Third* $\frac{5}{4}$ will be, 0 . 321928. [b]—[[a] See INTERVAL. [b] *Euler*. Tentam. Nov. Theor. Muſ. p. 109.]

The *third major* is by practitioners often taken for the *third* part of an octave; but this is a great error, ſince three greater *Thirds* fall ſhort of the octave by a dieſis: For $\frac{5}{4} \times \frac{5}{4} \times \frac{5}{4} \times \frac{128}{125} = \frac{2}{1}$; or by logarithms $3 \times 0 . 321928 +$ log. dieſis $= 0 . 965784 + 0 . 034215 = 0 . 999999$ or 1 . 000000 the logarithm of the octave. See the article DIESIS.

THIRD *Minor*. The logarithm or meaſure of the octave $\frac{2}{1}$ being 1 . 000000, the meaſure of the *third minor* $\frac{6}{5}$ will be 0 . 263034. Hence it appears that four leſſer *Thirds* exceed the octave. But practical muſicians are apt to ſuppoſe them equal to the octave, as they are apt to confound three greater *Thirds* with that interval. Three leſſer *Thirds* exceed the octave by a dieſis and a comma; as is eaſily proved by logarithms. *Euler*. Tent. Nov. Theor. Muſ. p. 109. See the article INTERVAL.

Diminiſhed THIRD, in muſic. We meet with ſeveral kinds of *Thirds* in the writings of muſicians, as greater and leſs, commonly called ſharp and flat; diminiſhed, ſuperfluous, deficient, and redundant. See the articles INTERVAL, DEFICIENT, REDUNDANT, &c.

THIRST (*Cycl.*)—It is ſaid, that thoſe who travel through the ſcorching deſarts of Arabia, Perſia, &c. find that brandy, and the ſtrongeſt wines, quench their *Thirſt* beſt. *Boyle*, Works abr. vol. 1. p. 52.

THISMA, a name uſed by ſome for any ſubterranean vein, or bed of a mineral.

THISTLE, *Carduus*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of ſeveral floſcules, which, at the upper end, are divided into ſegments, and ſtand upon the embryo ſeed. The general cup which contains theſe floſcules is of a prickly ſtructure; and the embryos finally become ſeeds winged with down. See Tab. 1. of BOTANY, Claſs 12.

The ſpecies of *Thiſtle*, enumerated by Mr. Tournefort, are theſe: 1. The calcitrapa, or ſtarry-headed *Thiſtle*. 2. The ſtarry-headed *Thiſtle*, with deep purple flowers. 3. The ſtarry-headed *Thiſtle*, with bright red flowers. 4. The ſtarry-headed *Thiſtle* with white flowers. 5. The ſtarry-headed *Thiſtle*, with broad jagged leaves, and large flowers. 6. The ſtarry-headed *Thiſtle*, with whole leaves ſerrated at the edges. 7. The yellow-flowered ſtarry-headed *Thiſtle*, with leaves like the blue-bottle or cyanus. 8. The yellow-flowered ſtarry headed *Thiſtle*, with leſs ſcaly or prickly heads. 9. The ſtarry-headed *Thiſtle* with undivided leaves, and purple flowers. 10. The aſſes *Thiſtle*, with ſmall heads, or the common wild *Thiſtle*. 11. The broad-leaved ſpear-*Thiſtle*. 12. The white-flowered broad-leaved ſpear-*Thiſtle*. 13. The very large and tall exotic ſpear-*Thiſtle*. 14. The very prickly *Thiſtle*, with alated and prickly ſtalks. 15. The purple-flowered *Thiſtle* with a bending head. 16. The white-flowered *Thiſtle* with a bending head. 17. The bear's-breech *Thiſtle*. 18. The common ladies *Thiſtle*, or milk *Thiſtle*. 19. The ladies *Thiſtle* with no white variegations. 20. The eryngo-like *Thiſtle* with prickly heads. 21. The great exotic milk *Thiſtle*, with brown ſeeds. 22. The galactite *Thiſtle* of John Bauhine. 23. The galactite *Thiſtle* with white flowers. 24. The common woolly *Thiſtle*, with acanthus-leaves. 25. The white-flowered woolly *Thiſtle* with acanthus-leaves. 26. The woolly acanthus-*Thiſtle* with narrower leaves. 27. The white-flowered woolly narrower-leaved acanthus-*Thiſtle*. 28. The very tall acanthus-leaved Portugal woolly *Thiſtle*. 29. The Portugal acanthus-leaved woolly *Thiſtle*. 30. The great-flowered Aleppo woolly *Thiſtle*, with acanthus-leaves. 31. The purple *Thiſtle* with round woolly heads,

32. The white-flowered *Thiſtle* with round woolly heads. 33. The Pyrenean woolly *Thiſtle*, with glomerated purple flowers. 34. The common *Carduus* or polycantha. 35. The Spaniſh polycanthus, with very ſhort leaves, armed with very long prickles. 36. The yellow centaury-like corn *Thiſtle*. This has been called by many, the yellow *knapweed* with prickly heads. 37. The hoary ſea-*Thiſtle*, with very tall ſtalks. 38. The hoary cretic *Thiſtle*, with a yellowiſh purple flower. 39. The hoary Portugal-*Thiſtle*, with alated ſtalks, and woolly heads. 40. The prickly round-headed *Thiſtle*, called by ſome the globular-headed jacea. 41. The ſuccory leaved purple Spaniſh *Thiſtle*. 42. The hairy jagged-leaved *Thiſtle*, with white flowers. 43. The powdered or duſty *Thiſtle*. 44. The knapweed-leaved *Thiſtle*, with ſmall heads and three-pointed ſcales. 45. The rockett-leaved Malteſe *Thiſtle*, with yellow flowers. 46. The Malteſe *Thiſtle*, with conglobated heads. 47. The Portugal-*Thiſtle*, with large hairy coronopus leaves, and yellow flowers. 48. The Portugal-*Thiſtle*, with hairy, rigid, coronopus-leaves, and ſaffron-coloured flowers. 49. The yellow Portugal-*Thiſtle*, with ſmooth and rigid coronopus-leaves. 50. The rape-leaved cretic *Thiſtle*, called by ſome the prickly *cyanus*, and prickly *knapweed* of Crete. *Tourn.* Inſt. p. 440. ſeq.

Gentle THISTLE, *Cirſium*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of a number of oblong floſcules, divided into many ſegments at their edges, and placed on the embryo ſeeds. Theſe are all contained in a ſcaly but not prickly cup; and the embryos finally become ſeeds winged with down; to this it is to be added, that the leaves are ſurrounded with ſoft prickles. The diſtinguiſhing characters of the *Cirſium* and jacea are therefore theſe: The *Cirſium* has prickly leaves, and not prickly cups, and the jacea has no thorns either on the leaves or cups.

The ſpecies of *Cirſium*, enumerated by Mr. Tournefort, are theſe: 1. The great *Cirſium* with aſphodel-roots. 2. The great *Cirſium*, with a large ſingle head, and purple ſtamina. 3. The great *Cirſium*, with a large ſingle head, and white ſtamina. 4. The great *Cirſium*, with a ſingle large head, and hoary divided leaves. 5. The great *Cirſium*, with a ſingle large head, and with green ſmooth leaves much divided. 6. The hoary large *Cirſium*, with ſingle heads, with large ſcales. 7. The *Cirſium* with ſmall ſingle heads. 8. The *Cirſium* with ſmooth leaves and compact flowers. 9. The *Cirſium* with narrow and undivided leaves. 10. The common narrow-leaved *Cirſium*. 11. The broad-leaved meadow *Cirſium*, with aſphodel-roots. 12. The aſphodel-rooted meadow *Cirſium*, with finely divided leaves. 13. The purple-flowered *Cirſium*, without a ſtalk. 14. The ſilver-ſpotted *Cirſium*. 15. The purple-flowered field-*Cirſium*, with creeping roots, and ſow-thiſtle leaves. 16. The white-flowered field-*Cirſium*, with creeping roots, and ſow-thiſtle leaves. 17. The creeping-rooted ſow-thiſtle-leaved field-*Cirſium*, with tuberous ſtalks. 18. The common many-headed meadow *Cirſium*. 19. The broad-leaved *Cirſium*, with burdock heads. 20. The low narrow-leaved *Cirſium*. 21. The mercury-leaved alpine *Cirſium*. 22. The *Cirſium* with very large leaves, of the ſhape of thoſe of the ferratula. 23. The many-headed *Cirſium*, with a winged ſtalk, and ſinuous leaves. 24. The alpine *Cirſium*, with leſs divided leaves, armed with very frequent and long prickles. 25. The three-headed alpine *Cirſium*. 26. The purple-flowered acanthoide alpine *Cirſium*. 27. The acanthoide mountain *Cirſium*, with yellow flowers. 28. The many-headed meadow alpine *Cirſium*, with aſphodel-roots. 29. The many-headed alpine *Cirſium*, with ſmall purple flowers, and prickly ſtalks. 30. The tall Pyrenean *Cirſium*. 31. The oriental *Cirſium*, with jagged leaves. *Tourn.* Inſt. p. 447.

Torch-THISTLE. See the article TORCH.

Globe-THISTLE. See the article ECHINOPUS.

THISTLE *Fly*, in natural hiſtory, a ſmall fly produced from a fly-worm, hatching in the protuberances of the carduus hæmorrhoidalis. In the protuberances of this *Thiſtle*, while they are cloſed in all parts, the worm of this fly, from whoſe injuring it, at the time of depoſiting the egg from which it was hatched, the protuberances aroſe, undergoes its laſt transformation. It here makes of its own ſkin a ſhell, in form of an egg, within which it puts on the nymph ſtate. When this nymph becomes a living fly, the leaſt part of its difficulty is the finding its way out of this ſhell; it has a much ſtronger priſon than that, and before it can obtain its liberty, muſt force its way through the much more cloſely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult work, but that of inflating its head, and throwing out the bladder or muzzle with which all theſe creatures are provided in this ſtate. See the articles NYMPH, MUSEAU, and THISTLE-*Galls*, infra.

This is a difficult operation, and many of the creatures periſh in the attempt; but what much forwards the ſucceſs of it, in many caſes, is, that the ſtalk of the *Thiſtle* often becomes naturally half rotten before the time of the fly's egreſs. *Reaumur*, Hiſt. Inf. vol. 4. p. 338.

THISTLE-*Galls*, a name given by the more accurate authors to the protuberances on the ſtalks of a ſpecies of *Thiſtle*, called by authors, *carduus hæmorrhoidalis*, from theſe tubercles, which are ſuppoſed to reſemble thoſe of the hæmorrhoidal veins, in perſons ſubject to the piles. Theſe have been ſuppoſed a natural production of the plant; but they are far otherwiſe. The whole hiſtory of them is, that the juices of this plant, being peculiarly agreeable to the worms of a certain ſpecies of fly, that creature always depoſits its eggs on the ſtalks; and the young ones, when hatched, gnaw their way into the ſubſtance of the ſtalk, and the copious derivation of the juice, occaſioned by their ſucking, produces the turbercles which are found on it. See Tab. of Inſects, N°. 28.

Theſe tubercles are of a roundiſh or oblong figure, and are of various ſizes, from that of a pea to the bigneſs of a nutmeg; they are much harder than the reſt of the ſtalk, approaching to a woody ſtructure; when cut open, they are found to contain each ſeveral oblong and narrow cells; theſe have no communication with one another, and are each inhabited by a ſmall white worm, which has two hooks at the head; with theſe it breaks the fibres of the plant, in order to get at its juices. When it has arrived at the time of its change into the nymph ſtate, it ceaſes to eat, and drawing up its body much ſhorter than uſual, its ſkin hardens, and forms a ſhell, under which it changes into a very beautiful two-winged fly.

The wings of this animal are of a very ſingular appearance; they are whitiſh and tranſparent in the middle, but ſurrounded at the edges with a border of black in the form of a chain of figures like the letter Z. When the fly is ſeen in ſome lights, the white parts of the wing is loſt, and the whole appears a circle of theſe notched figures.

The body and breaſt of this fly are of a beautiful black, with ſome ſlight variegations of yellow; and the ſhoulders are elegantly ſtreaked with the laſt colour. The anterior part of the head is white, which gives the creature a very ſingular appearance, and its back part is edged with a fine yellow down or hairyneſs. The antennæ are reddiſh; and the legs are in part black, and in part of a fine clear brown. In obſerving the changes of the worms of theſe galls, there are often obſerved ſome which go through them in a different manner from the reſt, and finally produce a very different ſpecies of fly. Theſe are the progeny of the eggs of ſome other ſpecies of fly, whoſe worm being carnivorous, is lodged by the art of its parent, while it is yet in the egg ſtate in the ſubſtance of this gall, there to prey upon the defenceleſs inhabitants.

There are many other ſpecies of galls, the inhabitants of which are expoſed to the ſame ſort of enemies. In thoſe it is common to find the proper inhabitant and the devourer in the ſame cell; the one feeding on the juices of the plant, the other on its juices; but this is not the caſe here, theſe worms immediately deſtroying the proper inhabitants, and being found always alone in their cells. *Reaumur*, Hiſt. Inſ. vol. 6. p. 221.

THLASIAS, a term uſed by the antients to expreſs an eunuch made by a compreſſion or contuſion of the teſticles, not by the cutting them out.

THLASIS, a word uſed by the antients to expreſs either a contuſion without a wound, or a wound made by ſome blunt inſtrument, which contuſed the parts.

THLASMA, a word ſometimes uſed like *thlaſis*, to expreſs a contuſion either with or without a wound; ſometimes applied particularly to a receſs of the cranium inward without a fracture, an accident principally affecting children.

THLASPEOS *Semen*, in the materia medica, the name of a ſeed produced by the common *thlaſpi arvenſe ſiliquis latis*, or common treacle muſtard. See the article THLASPI, infr.

It is a plant of about eight inches high; the leaves are broad and oblong, and the flowers are white, and each compoſed of four leaves. The ſeed-veſſels are broad and flat, and the ſeeds ſmall and dark coloured. It grows wild in England, but is not very common.

The ſeed ſhould be choſen clean and freſh, of a reddiſh caſt, and very ſharp, and biting on the tongue. Great care ſhould be taken in the buying this ſeed, becauſe it is often adulterated, and the ſeeds of common garden creſſes are too frequently ſold in its place. It is an ingredient in ſeveral of our ſhop compoſitions, and is eſteemed attenuating, deterſive and aperient, and is ſaid to promote urine, and the menſes, and to expel the after-birth. *Lemery*, Dict. of Drugs.

THLASPI, *Treacle Muſtard*, in botany, the name of a genus of plants, the characters of which are theſe: The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and finally becomes a roundiſh fruit, of a flatted ſhape, and uſually terminated all round with a foliaceous edge ſplit at the extremity, and divided by an intermediate membrane into two cells, which uſually contain a number of flat ſeeds. To theſe marks it is to be added, that all the *Thlaſpis* have whole, not divided leaves, in which they evidently differ from the *naſturtium*, or creſs kind.

The ſpecies of *Thlaſpi*, enumerated by Mr. Tournefort, are theſe: 1. The common *Thlaſpi*. 2. The ſmaller hoary-leaved *Thlaſpi*. 3. The field-*Thlaſpi* with broad pods. 4. The hairy podded *Thlaſpi*. 5. The *Thlaſpi* with heart-faſhioned pods. 6. The *ſecrodo-Thlaſpi*, or *Thlaſpi* ſmelling ſtrongly of garlick. 7. The larger perfoliated field-*Thlaſpi*. 8. The ſmaller perfoliated field-*Thlaſpi*. 9. The little red-flowered rock-*Thlaſpi*. 10. The purple-flowered alpine

alpine *Thlaspi*, with round fleshy leaves. 11. The little Portugal scurvygrass-leaved *Thlaspi*. 12. The little alpine *Thlaspi*, with thick narrow leaves. 13. The *Thlaspi* called the rose of Jericho. 14. The Virginian *Thlaspi*, with leaves like the Iberis, but broader and serrated at the edges. 15. The ever-green mountain-*Thlaspi*. 16. The candy-*Thlaspi*, with red and white flowers. 17. The bitter umbellated field-*Thlaspi*. 18. The lesser umbellated candy-*Thlaspi*, with white umbellated flowers of a sweet scent. 19. The grassy-leaved purple-flowered umbellated Portugal-*Thlaspi*. 20. The grassy-leaved umbellated Portugal-*Thlaspi*, with white flowers. 21. The rock-*Thlaspi*, with verniculated leaves. *Tourn.* Inst. p. 212. See the article THLASPEOS *Semen*, *supra*.

THLASPIDIUM, in botany, the name of a genus of plants; the characters of which are these. The flower consists of four leaves, and is of the cruciform kind. The pistil arises from the cup, and finally becomes a sort of double fruit, flat, and composed of two parts separated one from the other by an intermediate membrane, and each containing usually one long-shaped flatted seed.

The species of *Thlaspidium*, enumerated by Mr. Tournefort, are these: 1. The French *Thlaspidium*, with hairy leaves like those of hawkweed. 2. The hairy *Thlaspidium*, with auriculated flower-cups. 3. The pale yellow-flowered annual *Thlaspidium*. 4. The reddish-leaved *Thlaspidium*. 5. The ever-flowering shrubby *Thlaspidium*, with leucoium leaves. 6. The ever-flowering shrubby *Thlaspidium*, with variegated leaves. 7. The alkanet-leaved *Thlaspidium*. 8. The spiked Italian *Thlaspidium*. 9. The narrow-leaved smooth mountain-*Thlaspidium*. 10. The dwarf alpine rough *Thlaspidium*. *Tourn.* Inst. p. 214.

THLIBIÆ, in antiquity, a kind of eunuchs. See the article CASTRATION.

THOCOS, Θῶκος, in antiquity, the same with *Thacas*. See the article THACAS.

THOKES, in our old writers, fish with broken bellies, forbid by statute to be mixed or packed with *Tale-fish*. 22 Ed. IV. c. 2. *Blount*, *Cowel*.

THORACIS *Primus*, in anatomy, a name given by many of the anatomical writers to the muscle called by the French the *Souclavier*. See the article SUBCLAVIUS.

THORACIS *Quartus*, in anatomy, a name given by many of the earlier writers to a muscle called by the modern writers *serratus porticus inferior*. The same authors gave the name of *tertius Thoracis* to the *serratus posticus superior*.

THORÆ *Radix*, in the materia medica, the name of a root which keeps its place in the catalogues of officinal simples, but is seldom used.

The plant which produces it is the *Thora valdensis* of Gerard. It is kept in the gardens of the curious, but grows wild in the mountainous parts of Germany. The root is composed of a number of granules or small lumps, like that of the common ranunculus; the leaves are roundish and stand on small pedicles, and the stalks are about six inches high, and the flowers yellow, and like those of our common wild ranunculus's.

The root is acrid and corrosive, and the juice of the leaves is said to poison animals, and to have been used by the antients for that purpose. *Pomet's* Hist. of Drugs, p. 41.

THORAX (*Cycl.*) – Dr. Hoadley thinks it proved from Mr. Hales's experiments, in his vegetable statics and hæmastatics, that there is air in the cavity of the *Thorax*, between the lungs and the pleura. See his Lectures on Respiration.

Abscesses in the THORAX, or breast. One of the most remarkable accounts we have ever had of the effects of an abscess in the *breast*, is from Mr. Chicoyneau, of the academy of Montpelier, given in the Memoirs of the Academy of Sciences of Paris, in 1731.

The case was this: A young lady of about nine years old, of a thin habit, a sprightly temper, and dry constitution, seemed to be growing crooked, both her shoulders but particularly the left were more raised than they naturally should be, and her whole body became somewhat more bent than usual toward the right side. Mr. Chicoyneau was sent for at this time, to know whether any stop could be put to the progress of this bad arrangement of the parts. On examining the lady it was found, that though she was naturally lean, yet there was a fullness all about her shoulders, and that the edges of the shoulder blades toward the spine were so elevated as to have between them and the ribs a space of two fingers breadth wide; and the spine of the back, instead of running down in a perpendicular line was crooked, and from the fourth vertebra downwards was pushed out of its natural situation; this bending continued down to the loins, and formed a sort of arch, the convexity of which was toward the left-side, and was so sensible a little below the shoulder-blade, that it seemed two fingers breadth out of its place. It seemed from this that the consequences must be very bad, and that the young lady would inevitably fall into a terrible deformity, which neither art nor nature could prevent, and that the organs of respiration would be greatly injured, as is commonly the case in these bad arrangements of the parts.

Mr. Chicoyneau took his leave with giving her parents some flattering hopes that nature might restore the parts in their farther growth, as children whose bones are disordered by rickets often have them right again in more advanced years, and was intending to prescribe a slight regimen; when, about five days afterwards he was again called in on account of a fever which attacked the young lady with great violence, and was always worst during the night, going off by gentle sweating toward the morning; on thoroughly enquiring into the symptoms this appeared to be a putrid fever, and, beside all the other symptoms of that disease, the patient had a constant and terrible pain in her shoulders, and with this a very troublesome dry cough, and a difficulty of respiration, whence it appeared too plainly, that either the lungs or the pleura were threatened with an inflammatory fluxion: After twenty days the fever began to abate, but still did not quite leave her; and it was not long after when all the signs of an internal suppuration appeared, and Mr. Chicoyneau dreaded an incurable phthisis. The pulse after this grew much worse, and was very irregular; and two other physicians being called in, all agreed that the child had but few days to live, ordered only some gentle cordials, and acquainted the parents with the danger. When all hopes were over, the nurses acquainted the doctors on one of their visits, that since their last the patient had discharged by stool at several times a very large quantity of a white viscid matter, resembling pus; and that before every one of these evacuations the young patient had great irritations, and violent pains in the belly.

Nature had not given the patient over, though her doctors had, and soon shewed that she could do what baffled the efforts of art. The matter voided was found, on examination, to be true pus, with a very small mixture of blood, the voiding it by stool continued many days with the same frequency and violence, and the fever and other symptoms all going off at this time by regular degrees, the discharge was soon found to be critical, and there were some hopes of nature's performing a cure by it.

The discharge continued about twelve days, and at the end of a little longer time the patient was perfectly recovered. There is no doubt, from the cough and all the symptoms, that this matter was contained in the breast, and though it has appeared incredible to many, that matter thus formed should be taken up into the blood-vessels and carried in the course of circulation to the intestines, and there discharged, yet this case seems an incontestible proof of the possibility of it.

There remained now no danger to the patient, but that of the increase of her deformity by the progress of the displacing of the spine, and other bones, as there was all the reason in the world to believe, that during the time of this long and terrible illness these parts had grown much worse; but, on inspection, nature was found here to have been as good a physician as in the other case; and, to the amazement of all that were present, the bones were all found in their natural places.

It was easy to see from this, that the displacing of the bones had been wholly owing to this tumor within the breast, the inflammation and suppuration of which had occasioned all the illness the patient had endured. The tumor was doubtless formed in the posterior region of the *Thorax*, whence it enlarged itself afterwards, extending to the neighbouring parts, and as to this alone was owing the cause of the displacing the bones, it is no wonder that when this cause no longer subsisted, they again reassumed their places. Mem. Acad. Scienc. 1731.

Mr. le Dran remarks, that whenever any considerable quantity of pus is contained in either cavity of the *Thorax*, that side will appear larger than the other. Med. Eff. Edinb.

Wounds of the THORAX. The wounds of the *Thorax* or breast, are of three kinds; either the wound is inflicted on the external parts only, or it penetrates into the cavity of the breast; or thirdly, the contents of the *Thorax* partake also of the wound.

It may be discovered whether wounds do or do not penetrate into the cavity of the *Thorax*, either by the sight or by the hearing, observing whether any sound proceeds from the wound at the time of inspiration, by feeling with the probe or a finger, and observing whether they pass into the cavity, or meet with any resistance, by injecting warm water, which if the wound does not penetrate will return strongly upon you; and lastly, you will be convinced that it does not by the absence of bad symptoms, such as difficulty of breathing, fainting and sick fits, which always attend a wound that penetrates into this cavity. If the wound is found not to penetrate, it is to be treated as a common slight wound. But sometimes an external wound of this kind runs very deep, and obliquely between the muscles and the ribs, and is thereby rendered very difficult to be cleansed from grumous blood and matter; and the matter in this case frequently destroys the neighbouring parts, and produces ulcers, and very dangerous or incurable fistulæ; nay, sometimes it makes its way through the pleura, into the cavity of the *Thorax*, and forms an empyema, or brings on a phthisis, and death itself.

The great business in this case is to clear the sinuses from the blood and matter confined in them; and this is to be done either by pressure, or by ordering the wound to be sucked by

a

a healthy perſon, or by drawing it out with a ſyphon, or making farther openings with a knife. A proper ſyringe with its mouth applied to the wound, and a ſtrong ſuction made, often will fill itſelf with the confined blood and matter, and by repeating the operation prove of very ſignal ſervice.

In wounds that penetrate into the cavity, when a large quantity of blood is ſpilt into the cavity of the *Thorax*, the expanſion of the lungs, the office of reſpiration, and the courſe of the blood through the lungs are impeded, and the blood in the lungs being inſpiſſated by frequently being retarded there, life cannot be ſupported; but where the quantity of extravaſated blood is not ſo large as to occaſion theſe accidents, there ſtill is danger that it ſhould putrify by degrees, and corrupt either the diaphragm, pleura, or lungs, which muſt occaſion very bad ſymptoms, and finally death itſelf, and that in a ſhort time. When blood is extravaſated in the *Thorax*, we muſt therefore uſe all diligence to get it away. If the wound is inflicted on the middle or lower part of the *Thorax*, and has not a very narrow opening, it will be convenient to lay the patient upon the wounded ſide, and adviſe him to fetch his breath deep, or cough; and if the diſcharge is hindered by lumps of grumous blood ſtopping up the orifice, they muſt be removed with a probe, or with the fingers, or drawn out with a ſyringe. If the blood is become too thick to flow out of the wound, an injection of barley-water with the addition of a little honey of roſes and a ſmall quantity of ſoap muſt be uſed; this is to be injected, and the patient made afterwards to lie on the wounded ſide, to let it run out again; and this muſt be repeated, till it appears that all the grumous blood is waſhed away. But if the wound is ſo narrow and oblique that this method cannot be uſed, it muſt be enlarged with the inciſion-knife. Great caution is to be obſerved not to fatigue the patient too much, by attempting to diſcharge all the extravaſated blood at one time. It will be more ſafe to do it by intervals, at different times, eſpecially if he be ſubject to ſwoonings; but the wound muſt be kept open in the mean time, by introducing a ſilver or leaden pipe into it, or at leaſt a large tent with a ſtring faſtened to it. This method of cleanſing the cavity of the *Thorax* is to be repeated, till the diſcharge ſhall entirely ceaſe, and the external wound can be conveniently healed.

When a wound is made in the upper part of the breaſt, the patients lying on the wounded ſide cannot at all let out the matter in the cavity; but an opening muſt be made in the lower part of the *Thorax*, between the ſecond and third rib, counting upwards, if it is on the left ſide; but if it is on the the right ſide then between the third and fourth rib, about a hand's breadth from the ſpine. The place where the opening is to be made ſhould be firſt marked with ink, and the inſtrument generally uſed to make it is the *trocar*, which muſt be driven above the rib into the *Thorax* with great caution, and gentleneſs; after it has penetrated, the ſteel inſtrument is to be drawn out, and the pipe left in as a paſſage for the extravaſated blood to be let out by; and if it does not readily make its way out by this, its evacuation may be forwarded by the ſuction of a ſyringe. The trochar is in common uſe on this occaſion; but as the lungs are very liable to be wounded by the paſſing of this inſtrument forcibly into the cavity of the *Thorax*, it is better to divide the common integuments with an inciſion-knife, as alſo the muſcles and pleura, carefully avoiding the lungs, which are very apt to adhere to the pleura in this part; when this perforation is properly made, it is carefully to be kept open as long as neceſſary, and the wound above to be healed up as ſoon as poſſible.

The cavity of the *Thorax* being thus cleanſed, the wound is to be dreſſed once every day, and the dreſſing performed with all poſſible expedition; and the utmoſt diligence uſed to guard the contents of the *Thorax* from the injuries of the external air. *Heiſter*'s Surg. p. 70.

THOS, Θώς, in zoology, a name given to an animal of the wolf kind, but larger than the common wolf. It never touches men or cattle, and rather provides its food by cunning than open force; preying chiefly on poultry and water-fowl. *Hofm.* Lex. univ. in voc.

THOUGHTS, in a boat, a name given by ſeamen to the benches, on which the men ſit down to row.

THOWLES, in a boat, are thoſe pins in its gunnel, between which the men put their oars when they row.

THRACIA *Gemma*, a ſtone mentioned by Pliny, and deſcribed by him to be of three kinds; the one of a plain green, but a conſiderably deep and ſtrong colour, the other of a paler green without variegation, and the third ſpotted with blood-coloured ſpots. This is a ſhort deſcription, but the ſtone ſeems to have been a jaſper, of the nature of our green oriental jaſper and heliotrope.

THRACIUS *Lapis*, in the natural hiſtory of the antients, a ſtone often mentioned, and firſt called *benæ lapis*, from the place where it was firſt found, which was in the neighbourhood of Bina, or Bena, a town in Thrace.

It has been by ſome authors allowed a place in the catalogues of the materia medica; but it is impoſſible for us to ſay with any certainty which of ſeveral ſubſtances now known (which all anſwer in ſome degree to the accounts left us of it) is the real body they meant by that name.

It was an inflammable body, found in mines, and in the beds of rivers; and, in burning, afforded a very offenſive ſmell. Some of the late authors have ſuppoſed it was our common pit-coal, the antients expreſſed by this name; others, that it was jet; and others, the common cannel coal. *Hill*'s Theophraſtus, p. 34.

THRANITÆ, in the Roman trireme gallies, or thoſe which had three rows of rowers; thoſe of the upper row were called by this name, the ſecond the *Zygitæ*, and the loweſt *Thalamitæ*.

The *Zygitæ*, or middle row of men, in theſe veſſels took up but very little room, having a conveniency of moving their hands and oars under the ſeats of thoſe who ſat next before them.

Meibom, in his diſcourſe of the naval architecture of the antients, has proved that the builders of theſe veſſels found much better places for the ſeveral tires of rowers, than the commentators on the works of the authors who mention them have done; and that hence the vaſt height ſuppoſed neceſſary in theſe veſſels is much of it imaginary, and that the teſſaraconteris of Philopater, a veſſel ſaid to have forty tire of oars, may have been built and managed, though requiring four thouſand men to row it.

This author is of opinion, that according to the plan he has given of the Roman naval architecture, we might very much improve our own gallies and galleaſſes. He acknowledges our form indeed to be preferable in general to theirs; but would have the ſame proportions kept up by us that were by them in their long veſſels. *Meibom.* de Trirem.

THRASOS, a term uſed by Hippocrates, to expreſs a wildneſs and fierceneſs in the eyes of perſons, who approach to a delirium in fevers.

THRAUPIS, in zoology, the name given by many authors to the bird more commonly called *citrinella*; a ſmall bird of the ſize of a linnet, kept in cages in Italy for its ſinging, and of a green, yellow, and grey colour. See the article CITRINELLA.

THRAUSMA, a name given by the antients to a kind of gum ammoniacum, which was drier than the common, and more eaſily crumbled to pieces.

THRAUSTOMICTHES, in natural hiſtory, the name of a genus of compound earths. The word is derived from the Greek θραυστος, brittle, and μιχθεις, mixt.

The bodies of this genus are loams compoſed of ſand and a leſs viſcid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally uſed to make bricks; and there are ſeveral ſpecies of them. 1. A whitiſh one, dug in great plenty in Staffordſhire, and ſome other counties. 2. A browniſh white one very plentiful about London. 3. A pale yellow one, common in moſt parts of England at ſmall depths. 4. A ſharp rough one, of a deep yellow, dug near the town of Hedgerley near Windſor, and commonly called Windſor loame: It is not found in any other place, and is of great value; it makes the bricks uſed for the iron furnaces, and ſerves at the glaſs-houſes and among the chemiſts as a very ſtrong and valuable lute; and is not only uſed in England, but carried to Holland and Germany, and many other parts of the world. 5. A deep duſky yellow one, dug in moſt parts of England, near the ſurface. 6. A hard brown one, found at ſome depth in Buckinghamſhire, and uſually found full of ſmall ſhells: It is uſed for covering the ridges of barns, and copings of walls; and makes very firm and durable barn-floors. 7. A light pale brown one, the looſeſt and moſt friable of all the genera, uſed in many places for making the bell-founders moulds. 8. A yellowiſh brown one: This is common in moſt parts of the kingdom, and makes the fine red bricks uſed for ornamenting buildings. *Hill*'s Hiſt. of Foſſ. p. 424.

THREAD (*Cycl.*)—The *Thread* of the Laplanders is very fine, white and ſtrong, but it is of a very different nature from ours; they know nothing of flax or hemp, nor of any other plant whoſe ſtalks might ſupply the place of theſe in making *Thread*, but theirs is made of the ſinews of the rain-deer. They kill of theſe animals a very great number continually, partly for food, partly for the ſkins which they uſe in cloathing themſelves, covering their huts, and on many other occaſions; the ſinews of all that they kill are very carefully preſerved, and delivered to the women, whoſe province it is to prepare this neceſſary matter. They beat the ſinews very well, after having ſteeped them a long time in water, and then they ſpin them out.

The *Thread* they thus make is of any degree of fineneſs they pleaſe; but it never is any longer than the ſinew from which it is made. They uſe this in ſowing their cloaths, ſhoes, gloves, &c. and the trappings of their rain-deer. The *Threads* of the ſame ſinew are laid up together, and are all of a length; and as the different ſinews afford them of very different lengths, they accordingly pick out ſuch as the preſent uſe requires, both in regard to length and fineneſs. This ſort of thread is made with much more labour than ours; but it is greatly ſuperior to it on many occaſions, where ſtrength is rather required than beauty.

Theſe people have, beſides this, a way of making a ſort of yarn

yarn of sheeps wool, which they weave into garters and a sort of ribbands, used by way of ornament; but they place no value on it, because of its want of strength. *Scheffer's* Hist. Lapland.

Air-THREADS, a term used by some to express those fine long white filaments or thready substances, which we meet with in vast numbers floating about in the air, in August and September. The world has been much perplexed about the generation of these, till it was known that they were the work of spiders, and that they served these creatures to move from place to place by. They are long, downy, and very soft, and though they hold together when untouched, they stick to the fingers in handling, and easily break with a slight touch.

The greater number of spiders have the property of spinning this sort of *Thread*. The long-legged field-spider, called the *shepherd*, and some others, want it; these have nothing to do with the *Air-threads*, so much wondered at; but all the others, that is, all those which nature has endowed with a power of spinning, make them.

The general method of these creatures spinning and weaving their webs, is by letting down the thread and then drawing it after them, and so disposing it as they think proper; but in the midst of their work of this sort, if they are closely observed, they will be sometimes found to desist, and turning the tail to the contrary way of the wind they will emit a thread with great violence, no less than that with which a jet of water is discharged from a cock. In this manner they continue darting forth the thread, which the wind takes, and carrying it forward it soon becomes many yards long. Soon after this the creature will throw herself off from the web, and trusting herself to the air with this long tail, will ascend swiftly, and to a great height with it. The fragments of these lines, or the whole lines, and the spiders attached to them though unobserved, make these *Air-threads*, and the use nature destines them for, is evidently the wafting the creature along the air, and giving it an opportunity of preying on gnats, and many other insects that inhabit the air, out of the reach of these creatures by any other means.

The young spiders, as well as the old ones, have this property of spinning *Threads*, and sailing in the air by means of them; and it is common to see very minute spiders at the ends of very long lines. No one particular kind is famous more than the rest for this practice, but all that can spin, at the proper season of the year do it.

The threads themselves shew the use they are of to the creature in seizing its prey; for they, as well as the webs below, are usually found filled with the fragments of devoured animals, the legs of flies, and the like.

When the *Threads* are newly spun, they are always single, and are generally seen ascending up higher and higher in the air; but when they are seen coming down, they are found sometimes composed of three or four others, and either without any spider at the ends, or with two or three or more. It is plain that this happens from the meeting of these threads one with another in the air, and their tangling together; and this incommodes the creatures, and brings them down. The whole process of the workmanship of these threads is easily seen, by observing some of the spiders which have not yet mounted into the air, but seem to be meditating their flight. It is common to see one of these creatures at such a time mount the top-most branch of a bush, and from thence dart out at its tail one after another several of these long *Threads*, by way of assaying what it can do, and how it shall like them. When the creature has darted out a thread to the length of several yards, it will of a sudden draw it all up again, and wind it up into a link with its fore-feet; but more frequently they break it off, and let it go. One spider will sometimes dart out, and break off in this manner a great number of *Threads*, before it spins one that it will trust to; but at length it will please itself with some one, and commit itself to the air on it.

These broken *Threads* are what fill the air with the loose threads we see in autumn; and as these soon entangle together, and bring one another down, it is no wonder that they are more frequent in the lower regions of the air, than those with the spiders adhering to them, which usually rise to great heights, and sustain themselves there. And hence the origin of the *Threads* was much perplexed among the enquirers, because they were found without any mark of the animal to which they owed their existence. The business of feeding is not all the use of these *Threads*, but the creatures evidently sport and entertain themselves by means of them, floating about in the air, and changing height and place at pleasure.

When a spider has once raised itself from the earth in this manner, it does not descend always on the same *Thread* it arose by, but draws that up at times, and winds it up into a hank with its fore-feet, and darts out another by way of support; and the new *Thread* is made more or less long, as it is intended for a higher or lower flight.

These *Air-threads* are not only found in autumn, but even in the depth of winter. The serene days about Christmas bring out great numbers of them; but the *Threads* are at this season only short and slender. They are the produce of the young spiders, hatched only the autumn before, and are seldom used to sustain the animal, but seem a mere sporting of it, being thrown out and broke off at small lengths. The thicker ropes of the autumn are the only ones intended for the support of the old spiders in the air, when there is plenty of small flies that inhabit the airy region, and make it worth the creature's while to take up its habitation among them. Phil. Trans. N°. 50.

THREX, among the Romans, an appellation given to gladiators, either because they were natives of Thrace, or wore armour after the manner of that country. *Pitisc.* in voc.

THRIFT, *Statice*, in botany. See the article STATICE.

The several more common species of this plant have been used to be raised promiscuously for making the edges of flower-beds, instead of box; but the necessity of transplanting them every year to keep them within due bounds, has made them of late much disused.

They are all propagated by parting their roots; the best time for doing which is in autumn, and they will grow with very little trouble, and flower in the May following, continuing in flower about three weeks or a month, if the weather is not too dry. *Miller's* Gardener's Dict.

THRIO, Θρίω, in antiquity, a festival in honour of Apollo. *Potter*, T. 1. p. 405.

THRIPS, in natural history, a name used among the antients, to express a sort of worm hatched from the egg of a beetle; which, while in the worm-state, eats its way into wood, and forms cells and cavities in it of various shapes, and in various directions, often resembling the figures of letters or other things.

The antient Greeks are said to have used small pieces of the wood thus eroded in particular forms, as seals before the engraving of these utensils was invented, and indeed they must very well have served this purpose, since it is scarce possible to conceive how one of these pieces of corroded wood should be counterfeited, or the impression imitated.

Lucian mentions his marking his olives with a signature of one of these pieces of wood greatly eroded, and uses the word *Thrips*, not as the name of the animal, but of the piece of wood eroded by it. Theophrastus, Pliny and Aristotle, also use the same expression; and we find that the word *Thrips* was as frequently used to signify the pieces of wood eroded, as the animal which eroded them.

THRISSA, in ichthyology, the name given by the Greeks and by the modern Latin writers, to the fish which we call the *shad*, or the mother of the herrings.

This is called by Artedi the clupea, with the top of the upper jaw divided, and with black spots on each side. This accurate author observes also, that the *agonus* or *agone* of Salvian, the *saracbus* of Charleton, and the *alosa minor* and *harengus minor* of Willughby, and others, which we call the pilchard, differ only from the *Thrissa* in size; all being the varieties of the same species of fish, and all charactered by this specific name.

THROAT (*Cycl.*)—*Sore*-THROAT, in medicine. See the article QUINZY, *Cycl.* and *Suppl.*

THROAT-*Wort*, in botany, the name of a plant of the bell-flower kind, called in Latin *Trachelium*. Its characters and species, see under that head.

This plant yields, when wounded, a milky juice in great plenty, and this if received into a shell or other small vessel, curdles immediately, and the whey runs from the thick part; this whey is of a brown colour, whereas that of the wild lettuce is of a fine purple, and dries into a cake that may be crumbled into a purple powder. The juice of the *Throat-wort* smells sour, and its curdled part being dried burns like resin at the flame of a candle. Phil. Trans. N°. 224.

THROMBUS, a word used by some medical writers, to express a grume or clot of blood.

THROSTLE, an English name for the common mavis, or song-thrush. See TURDUS.

THROWING, among bowlers. See the article BOWLING.

THRYALLIS, in botany, a name given by Nicander, and some other writers, to a species of mullein used in the coronæ and garlands of the antients; and, as he expresly says, different from the common wild mullein.

Dioscorides seems to make this his third species, and calls it *lychnitis*, from its use in lamps; the Greeks beating out its thready stalks, and using them for the wicks of lamps. We have a kind of *verbascum*, or mullein, which we call *lychnitis*, in commemoration of Dioscorides's name; but it does not appear to be the same species that Nicander and the other Greeks called by that name. Some also called it *nekeia*, or *necuia*, from its use in making a kind of torch; that was the thing with which they kindled the funeral piles of the dead.

THUMB, *Pollex*, in anatomy, one of the members, or parts of the hand. See the article HAND, *Cycl.* and *Suppl.*

The first phalanx of the bones of the *Thumb* is not like those of the other fingers. Antient authors reckon it among the bones of the metacarpus, which it resembles very much, and by this means allow only two phalanges to the *Thumb*, and

make five metacarpal bones. The convex fide of this phalanx is very much flatted, and is much broader toward the head, than toward the bafis. On the concave fide is a kind of angular line, which in fome meafure diftinguifhes it into two parts. Its head is like thofe of the metacarpal bones, only flatted at top. The articular fide of its bafis is proportioned to the digital fide of the *os trapezium* of the carpus, and framed in fuch a manner as that the figmoide cavities and eminences in the two bones crofs one another. This articulation has fomething very particular in it; it is a kind of double ginglymus, which readily allows of flexion and extenfion, adduction and abduction, but with difficulty permits the oblique motions, becaufe then the two fides run counter to each other.

The fecond phalanx of the *Thumb* is fhorter than the firft; its body is convex or femi cylindrical on one fide, flat on the other, and contracted between the edges. The articular fide of the bafis is gently concave, and is furrounded near the edges by fmall tuberofities; as alfo near the angle of the phalanx. The head is the regular portion of a pulley, which projects more on the concave, than on the convex fide; and on each fide of it there is a fmall foffula, and fome inequalities in form of tubercles. On the flat or concave fide of the phalanx are two rough lines, one near each edge; they are the impreffions or marks of the articular vaginæ. The connection of this phalanx with the firft, is by a kind of arthrodia, or by a flat enarthrofis, which permits a motion in feveral directions, though more limited than in other articulations of the fame kind. It is articulated with the third by a very perfect ginglymus.

The third phalanx of the *Thumb* reprefents the half of a fort of cone, cut lengthwife, and by joining it to the fame bone of the other *Thumb*, an entire cone is formed; the convex fide is more even than the flat fide, and on each edge there is a tuberofity near the bafis: The bafis has two hollow fides, which form a ginglymus with the head of the fecond phalanx The head is flat and fmall, ending in a rough femi-circular border, which on the flat fide of the bone reprefents a horfe-fhoe. *Winflow*'s Anat. p. 87.

THUNDER (*Cycl.*)—The noife of *Thunder* and the flame of lightning are eafily made by art. If a mixture of oil or fpirit of vitriol be made with water, and fome filings of fteel added to it, there will immediately arife a thick fmoak, or vapour, out of the mouth of the veffel; and if a lighted candle be applied to this, it will take fire; the flame will immediately defcend into the veffel, and this will be burft to pieces, with a noife like that of a cannon.

This is fo far analogous to *Thunder* and lightning, that a great explofion and fire are occafioned by it; but in this they differ, that this matter when once fired is deftroyed, and can give no more explofions; whereas in the heavens one clap of *Thunder* ufually follows another, and there is a continued fucceffion of them for a long time. Mr. Homberg explained this by the lightnefs of the air above us, in comparifon of that here, which therefore would not fuffer all the matter fo kindled to be diffipated at once, but kept it for feveral returns.

THUNDER-*Stone*, in natural hiftory, the fame with that called by authors *Brontia*. See the article BRONTIA.

THUNDER-*Storms*. It is frequent in the *Thunder-ftorms* in hot climates, to fee a bituminous matter fall with the lightening to the ground, and there continue for fome time burning in a mafs, or elfe burft at once into a multitude of fparks, which burn every thing they touch, and always leave a violent fmell of brimftone behind them.

Something of this nature, but concreted into a folid form and refembling common brimftone, was fome years ago obferved in the ifle of Wight; of which Mr. Cook, an inhabitant of Newport there, has given the following account:

The month of July, in the year 1737, had been very fultry, and the nights often ftormy, in particular there was one evening a very violent ftorm of *Thunder* and lightening, attended toward the end with a great deal of rain. The morning afterwards, as a countryman was walking over a meadow near the fea-fide, he obferved a yellow ball of a fhining matter, lying loofe upon the turf or grafs. When he had taken it up, he found it to be no other than a lump of fulphur, of an uncommonly ftrong fmell, and covered all over with a multitude of fine fhining cryftals of a yellowifh colour, which fell off on the lighteft touch. The whole fubftance appeared to be fomewhat fpungy, and it had a large hole in one part; it was near an inch long, and fomewhat more than half an inch in diameter, and when put to the fire proved readily inflammable, and burnt with a whiter flame than common brimftone, and with lefs acid and fuffocating fumes.

The author of this account feems to think, that there is great probability that this ball was generated, not under ground but in the air, and that it was of the nature of thofe maffes of bituminous matter falling fo frequently in *Thunder-ftorms*, in the hotter countries, but that by fome accident it miffed taking fire, and was therefore left perfect in its folid form. It feems not to have been generated under ground, fince if it had, it could never have been found on the furface fo perfectly clean, with its pores all empty not filled with earth, and its covering of cryftals untouched, though they adhered fo very lightly to it that the gentleft touch threw them off. Phil. Tranf. N°. 450. p. 449.

THURIBULUM, among the Romans, a cenfer or veffel, in which incenfe was burnt at facrifices. *Pitifc.* in voc.

THURIFICATI, in church hiftory, a defignation given to thofe, who, to avoid the perfecution of the Roman emperors, offered frankincenfe to the heathen gods. *Hofm.* Lex. in voc. See the article PERSECUTION.

THURSIO, in ichthyology, a fpecies of fifh, mentioned by Pliny, l. 9. c. 9. It is thought by fome to be the *Phocæna*, or porpoife; and by others the *Sturgeon*. *Hofm.* Lex. univ. in voc. See the articles PORPOISE, and STURGEON.

THURUS, in natural hiftory, the name of a creature defcribed by Gefner, and fome others, as a diftinct fpecies of wild bull; but the accounts of it feem either fabulous, or miftaken defcriptions of the wild bull. See the article Bos.

THUYA, *Tree of life*, in botany the name of a genus of trees, the characters of which are thefe: The embryo fruits are of a fquammofe ftructure, and finally become a fort of oblong fruit, between the fcales of which there lie a fort of marginated feed. To this it is to be added, that the leaves are fcaly.

The fpecies of *Thuya*, are the common *arbor vitæ*, and the Chinefe kind. *Tourn.* Inft. p. 587.

THWART *the Hawfe*, in the fea language. See the article HAWSE.

THYIA, Θυια, in antiquity, a feftival in honour of Bacchus, celebrated by the Eleans. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 405.

THYITES *Lapis*, in the materia medica of the antients, the name of an indurated clay, approaching to the nature of a ftone. It was found in Egypt, and ufed in diftemperatures of the eyes.

This fubftance has been very much mifunderftood by the late writers, and by moft of them fuppofed to be loft at this time; but this was wholly owing to their miftaking the clafs of bodies among which they were to look for it. Some imagining it to have been a fpecies of green marble; and others the turquoife-ftone, that Diofcorides meant by this name. It is very plain however, that it was no other than an indurated clay of the morochthus kind, and no more a ftone than that fubftance, that being alfo frequently called *lapis morochthus*.

It is of a fmooth, even and regular texture, very heavy, of a fhining furface, and of a pale green, without the admixture of any other colour. It does not at all adhere to the tongue, nor ftain the fingers in handling; but drawn along a rough furface, leaves a flender white line. It melts flowly in the mouth, and is of a fharp acrid and difagreeable tafte; and when rubbed down with water on a marble, it melts into a milky liquor of a pure white, not the leaft greennefs being fenfible in it. It is found at prefent in the great mine at Goffelar in Saxony, and feems to owe its colour to particles of copper; to which alfo it owes the virtues attributed to it by Diofcorides, acting as a weak kind of verdigreafe. *Hill*'s Hift. of Foff. p. 36.

THYLACION, a word ufed by the antient medical writers, to exprefs the bag formed by the membranes of the fœtus at the orifice of the pudenda, before the birth.

THYLLA, Θυλλα, in antiquity, a feftival in honour of Venus. *Potter*, T. 1. p. 405.

THYMALLUS, in ichthyology, the name of a fifh of the truttaceous kind, called in Englifh the greyling, or umber.

It is of a long and flatted body, the belly is fomewhat broad, and the back rigid and thin. It feldom exceeds a pound, or at the utmoft a pound and half weight. Its back is of a dufky brownifh green, with a fomewhat bluifh caft intermixed, and its fides of a more blue fhining glofs with an admixture of gold colour. The fcales are of a fort of rhomboidal form, and the fide-lines are much nearer the back than the belly. The fides are variegated with black fpots placed irregularly; but there are none of thefe near the tail. The back has two fins, and the tail is forked. The head is fmall, the eyes large and protuberant; the mouth is moderately large, and the upper jaw larger than the under; it has no teeth, but the whole jaws are rough like a file.

It is caught in the frefh rivers in the mountainous counties of England, and in the like fituations in Germany, and other kingdoms, and is one of the fineft tafted of all the frefh-water fifh. It feeds on worms, and fpawns in May. See Tab. of Fifhes, N°. 31. and *Willughby*'s Hift. Pifc. p. 187.

THYMBRA, in botany, the name of a genus of plants; the characters of which are thefe: The flowers and feeds are in all refpects like thofe of thyme, but that they are placed verticillately round the ftalks.

The fpecies of *Thymbra*, enumerated by Mr. Tournefort, are thefe: 1. The *Thymbra*, fimply fo called, and named by others *candy favory*. 2. The Spanifh *Thymbra*, with leaves like marjoram, called *marum*, and *maftichina*; and by fome *clinopodium*. 3. The roundifh-leaved Spanifh *Thymbra*. 4. The Spanifh *Thymbra*, with leaves like the coris, called by fome *ferpillum*; and by others a fpecies of thyme. And, 5. The St. Julian *Thymbra*, or true favory, called alfo by fome fpiked favory, and the St. Julian's Savory. *Tourn.* Inft. p. 197.

THYME, *Thymus*, in botany, *&c.* See the article THYMUS.

THYMELÆA, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is funnel-shaped, and cut into four segments at the edges; from the bottom of this there arises a pistil, which finally becomes an oval fruit; which in some species is succulent, and in others is dry; but in all contains oblong seeds.

The species of *Thymelæa*, enumerated by Mr. Tournefort, are these: 1. The flax-leaved *Thymelæa*. 2. The African flax-leaved *Thymelæa*, with pale-coloured, and very sweet-scented flowers. 3. The African flax-leaved *Thymelæa*, with broad, obtuse, and shining leaves. 4. The African flax-leaved *Thymelæa*, with flowers collected into clusters. 5. The dwarf alpine flax-leaved *Thymelæa*, with purple sweet-scented flowers. 6. The dwarf alpine flax-leaved *Thymelæa*, with sweet-scented white flowers. 7. The small hairy knot-grass-leaved Portugal *Thymelæa*. 8. The common toad-flax-leaved *Thymelæa*. 9. The Spanish *Thymelæa*, with toad-flax-leaves. 10. The African *Thymelæa*, with very narrow, and short rosemary-like leaves. 11. The African *Thymelæa*, with long and narrow rosemary-like leaves. 12. The rosemary-leaved African *Thymelæa*, with long flowers. 13. The white-flowered shrubby African *Thymelæa*, with rosemary leaves. 14. The Spanish *Thymelæa*, with broad olive-like leaves. 15. The Italian silvery olive-leaved *Thymelæa*. 16. The olive-leaved rock *Thymelæa*. 17. The white-flowered alpine *Thymelæa*, with leaves hoary on both sides. 18. The smooth *Thymelæa*, with leaves like the polygala. 19. The hairy *Thymelæa*, with polygala-leaves. 20. The chamelæa-leaved *Thymelæa*, with short hairy leaves. 21. The woolly kali-leaved *Thymelæa*. 22. The juniper-leaved *Thymelæa*, with procumbent branches. 23. The Pyrenean juniper-leaved Thymelæa, with erect branches. 24. The African *Thymelæa*, with narrow heath-like leaves. 25. The *Thymelæa*, with white, soft, and silky leaves. 26. The African *Thymelæa*, with tufted flowers. 27. The woolly *Thymelæa*, with small houseleek leaves. 28. The Spanish *Thymelæa*, with hoary myrtle-like leaves. 29. The African *Thymelæa*, with butcher's-broom leaves. 30. The shrubby African *Thymelæa*, with milkwort-like leaves and jasmine flowers. 31. The narrow-leaved jasmine-flowered African *Thymelæa*. 32. The nepa-leaved prickly African *Thymelæa*, with small purple flowers. 33. The ever-green bay-leaved *Thymelæa*, called the *laureola mas*, or male spurge-laurel. 34 The bay-leaved *Thymelæa*, with deciduous leaves, called the female spurge-laurel. And 35. The bay-leaved *Thymelæa*, with deciduous leaves, with white flowers and yellow fruit. *Tourn.* Inst. p. 494.

THYMELÆÆ *Radix*, in the materia medica, the dried root of the *Thymelæa foliis lini* of Tournefort and other authors.

It is a light root of different sizes, of a reddish colour without, and greyish within, woody, and full of fibres, and tastes sweet at first, but is hot as fire when it has been held a little time in the mouth. It loses however both this fiery taste, and its acrid quality, in long keeping, and with them its virtues.

It is to be chosen new, well fed, and not worm-eaten. The fruit of this plant is the *granum cnidium* of the shops. They are both of an acrid quality, and are not in use in the shops at present. *Pomet*'s Hist. of Drugs, p. 46.

THYMELÆA is also a name by which some authors have called the *laureola*, or spurge-laurel, an ever-green shrub, common in our woods: But it is more usually made the name of the *mezereon*, or spurge-olive, and, with many, is understood only as the name of the spurge-flax. *Tourn.* Inst. p. 415. *Boerhaave*'s Index, vol. 2. p. 213.

THYMELE, in the antient theatre, a kind of pulpit, where the fingers called *thymelici* performed. See the articles THYMELICI and LOGEUM.

THYMELICI, among the Romans, were musicians, who sung in the interludes, or who danced and kept time with their gestures. The place where they performed was called *Thymele*, whence Juvenal. VI. 66.

Attendit thymele, thymele nunc rustica discat.

THYMIAMA, Θυμιαμα, in antiquity, an offering of incense to God. See the article INCENSE, *Cycl.*

THYMIAMA, in the materia medica, a name by which some authors have called the *cascarilla bark*; called by some *cortex thuris*, or Indian bark. *Ray*'s Hist. Pl. vol. 2. p. 1841.

THYMIAMATA, a kind of fumigations among the antients, the ingredients of which were so various, that it appears they always consulted utility as well as pleasure, in their composition of them. Many of the ingredients, named in the oldest prescriptions for the making them, being the names of things not sweet-scented, the commentators have supposed that the antients expressed other things by those words, and not those which we at present mean by them; but all this is founded on the error of supposing these things intended only as sweet-scented preparations.

We find the gum ammoniacum of the antients used in them: And Neophytus reconciles the use of it in this manner very easily, by alledging, that it had the smell of coriander-seeds, which, as he observes justly, is an agreeable scent, and might do very well in mixture with others of this kind. It is pretty certain, that the ammoniacum of the antients was not the same gum which we now know by that name; but as the account of Neophytus, as to its smell, comes from an older Greek author, Dioscorides, we are to refer to him for the certainty of the expression; and by this it appears that Neophytus errs greatly, in attributing to ammoniacum the smell of coriander-seeds; for that the word used by Dioscorides, and which he has translated coriander, is κορὶυ; and this, as we find by many other passages of the same author, is an abbreviation of the word *castorei*, καστορίυ.

The smell of castor is also attributed to ammoniacum by Theophrastus and others; whence it is evident that the antients used salutiferous as well as sweet-scented things in these fumigations. Galbanum is a worse smell than ammoniacum, and yet this also we find, together with myrrh, and other gums, is made an ingredient in the oldest prescriptions of this kind. And Pliny mentions the ammoniacum with the schænanth, and other sweets used for this purpose.

THYMOXALME, in the materia medica of the antients, was a composition used externally in the gout, and many disorders of the limbs, and was given inwardly in distemperatures of the stomach, a quarter of a pint for a dose. It operated as a purge, and was prepared in the following manner: Take two ounces of bruised thyme, as much salt, a little meal, rue, and penny-royal. These were to be put into a pot, and three pints of water, and fourteen ounces of vinegar are to be poured upon them; after which they are to be covered with a coarse cloth, and set in the sun for some time. *Dioscorides*, l. 5. c. 24.

THYMUS, *Thyme*, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, and is of the labiated kind: The upper lip is erect, and usually bifid, and the lower is divided into three segments. The pistil arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and surrounded by four embryos, which afterwards become as many seeds, and ripen in the cup of the flower. To these marks it may be added, that the stalks are usually hard and woody, and the flowers collected into heads.

The species of *Thyme*, enumerated by Mr. Tournefort, are these: 1. The common-headed *Thyme*. 2. The common broader-leaved *Thyme*. 3. The common narrow-leaved *Thyme*. 4. The white narrow-leaved strong-scented *Thyme*. 5. The white procumbent sweet scented *Thyme*. 6. The scentless *Thyme*. 7. The small-headed *Thyme*. 8. The Portugal *Thyme*, with narrow hairy leaves, and large long purple heads. 9. The Portugal *Thyme*, with narrow hairy leaves, and round heads of purple flowers. 10. The great-headed Portugal *Thyme*. 11. The small-headed Portugal *Thyme*. 12. The headed Portugal *Thyme*, with large scales. *Tourn.* Inst. p. 196.

We have three or four species of this plant propagated in our gardens, partly for use in the kitchen, and partly for curiosity. They are propagated either by sowing, or by parting the roots, both which should be done in March.

The seeds should be sowed on a bed of light earth, and must not be buried too deep. When they come up, they must be kept clear of weeds, and watered at times; and in June they should be thinned, leaving the plants at about six inches asunder. After this they will grow very fast, and will require no farther care.

If they are to be propagated the other way, the roots should be taken up, and parted into as many slips as can be, and each planted at six or eight inches distance, on beds of light earth, watering and shading them till they have taken root.

The common garden *Thyme* is a cephalic. It also is good in all obstructions of the viscera, in the rheumatism, and in flatulencies.

The serpillum, or wild mother of *Thyme*, is one of the greatest nervous simples of our own growth. An infusion of it alone will do wonders in tremors, lowness of spirits, and headachs. It makes a very agreeable liquor, drank in the manner of tea, and this, continued for some time, has proved a remedy in many cases where every thing else has failed. It is almost infallible in the cure of that troublesome disorder the nightmare.

THYMUS, (*Cycl.*) in anatomy. Dr. Pozzi says, that the *Thymus* of a calf, softened by maceration, discovers a lobe, from which a milky liquor runs out when wounded; and if air is afterwards blown into it, the whole *Thymus* is distended, and may be dried, when it plainly appears to be composed of cells communicating with each other; upon the sides of which muscular fibres are to be seen: From which structure he concludes, that the *Thymus* in fœtuses supplies the use of the lungs, serving as a receptacle for the chyle to be prepared in. Med. Ess. Edinb.

The *Thymus* is thought by some to furnish the liquor found in the thorax of fœtuses. See Mem. de l'Acad. des Scienc. Par. 1733.

THYNNIA, Θυννια, in antiquity, a sacrifice offered to Neptune by the fishermen, after a plentiful draught.

The word comes from Θυννος, a tunny, that being the sacrifice offered.

THYNNUS, in ichthyography, the name of a fish called in English the *tunny*, or Spanish mackrel, common in the Mediterranean,

diterranean, and others seas, and sometimes, though not frequently, caught on the English coasts.

It is a very large fish, growing sometimes to seven or eight foot long, and more than an hundred weight. It is of a rounded and thick body, growing gradually smaller toward the tail, till it is at length extremely slender. It very much resembles the *pelamys* in its whole figure, but that it wants the oblong black streaks which that fish has on its sides, and is much larger. The back is black, or, if held in some lights, is of a shining bluish or greenish hue. Its belly and half its sides are of a silvery whiteness. Its scales are very small. Its snout pointed. Its jaws both of equal length, and armed each with one row of teeth. The mouth is large and black within, except that part of the palate is red. The eyes are large. The larger black fins are two in number; the foremost placed near the head, and rising out of a cavity in the back, and the other at a small distance behind that; and, in some fish of this species, of a reddish or yellowish colour; and behind this last, there are eight, nine, or ten small fins running down the ridge of the back at equal distances to the tail. The tail is very forked. The fins at the gills are black, small, and terminate in a point. The belly fins are placed but at a small distance behind these, and are also small; and both these, and the gill-fins have sinuses in the body of the fish, into which they may be depressed. Behind the anus is a fin like that on the back, and behind it eight more small ones, answering to those on the back also; and the skin of the sides, near the tail, is extended into two fins; so that this part of the fish looks in some sort square. It is a good fish for the table, and is salted in vast quantities in Spain and Italy. See Tab. of Fishes, N°. 29. and *Ray*'s Ichthyography, p. 176.

THYOS, Θυος, in antiquity, an offering of fruits, leaves, or acorns, which were the only sacrifices at first in use. *Potter*, Archæol. Græc. T. 1. p. 213.

THYREOSTAPHILINUS, in anatomy, a name given by Douglass to a muscle, called by Albinus and others, *palatopharyngæus*. See the article PALATOPHARYNGÆUS.

THYRRÆUM *Vinum*, a sort of wine among the antients remarkable for its thickness and dark colour; it was sweet, and luscious, and not astringent.

THYRREUS *Lapis*, in natural history, the name of a fossil, which the writers of the middle ages have called *syrus*.

It has many virtues ascribed to it; but all the account we have of its real properties are from Pliny, who observes that it swam upon the water while whole; but when broken into small pieces, these sunk to the bottom. It seems to have been a sort of bitumen of a spongy structure.

THYSSELINUM, in botany, the name of a genus of umbelliferous plants, the flowers and fruit of which are the same with those of the *petroselinum*, or mountain parsley; from which it differs in nothing, except that it yields a milky juice when broken or wounded.

The species of *Thysselinum*, enumerated by Mr. Tournefort, are these: 1. The *Thysselinum* of Pliny, or milky parsley. 2. The marsh *Thysselinum*, called by some the *milky seseli*. *Tourn.* Inst. p. 319.

TIBERIADES *Water*, the water of a hot spring near *Tiberiades* in Egypt.

Dr. Perry, when on the spot, tried some experiments on this water, which give us a much better idea of its nature, than we have from any other accounts of it. Half a dram of oil of tartar being mixed with an ounce and half of the water, it becomes turbid and muddy; and after twelve hours, three parts of the whole appear like white wool, only leaving a small portion of clear water at the top. This white woolly matter dried, produced only a small quantity of yellow ochre.

Spirit of vitriol added to the water in the same quantity, affords a large unctuous sediment of a white colour. A solution of sublimate being mixed in the same quantity, it became turbid and yellowish, and yielded an earthy sediment in small quantity; whence it seems evident, that it contains a sal murale. Saccharum saturni being added in the same quantity, the water deposited a lateritious sediment in a small quantity. Mixt with spirit of sal armoniac, it turns to a bluish green turbid liquor, and finally yields a woolly sediment. Sugar of violets mixed with it, turned it to a yellowish colour; and the scrapings of galls mixed with it, turned it to a deep purple; and on shaking, this became as black as ink.

It appears from these experiments, that the water contains a good deal of a gross fixed vitriolic salt, some alum, and a sal murale. It is too salt and nauseous for internal use; but it must be of use as a bath in all cutaneous foulnesses, especially in scorbutic and leprous cases; for it will powerfully deterge, scour and cleanse the excretory pores, and it may, by its weight and stimulus, restore them to their natural state and tone, and restore the true state of the vitiated solids in general. Phil. Transf. N°. 462. p. 52.

TIBERIANUM *Marmor*, in the natural history of the antients, the name of the green and white marble, common in tables, &c. at this time, and by our artificers called *Ægyptian marble*. The Romans applied this name, however, only to one appearance of this species of marble, which was, when its white part was not arranged into regular lines, or arched figures, but diffused irregularly through the whole mass; for where it was thrown into these sort of arches, it was called the *augustan* marble. These were, however, very idle distinctions, since the same block, to this day, often affords us the white veins, in both these dispositions, in its different parts.

The antient Romans had it from Ægypt, and we also have the finest pieces thence; though the greater part of what we use is not brought quite so far. *Hill*'s Hist. of Foss. p. 481.

TIBERIANUM *Tormentum*, in medicine, a name given by some to the colic. See COLIC.

TIBIA (*Cycl.*)—*Cartilages of the* TIBIA. The *Tibia* has four or five proper cartilages, and two additional ones. The two proper cartilages which cover the two superior surfaces of the head of the *Tibia*, are the thickest. These are both gently hollow; but the internal, or that next the other *Tibia*, is more depressed in the middle than the other. The third proper cartilage covers the small surface which lies on the lower part of the external condyle. The fourth covers the lower surface of the basis of the *Tibia*, being continued over the outside of the inner ankle. There are likewise superficial cartilaginous incrustations on the back part of this basis, behind the inner ankle, and likewise on the backside of the outer ankle, all for the passage of tendons.

The additional cartilages of the *Tibia* are two in number, called semilunar from their figure, and intermediate or interarticular from their situation; each of these cartilages is in the shape of a crescent, or Roman C. Their convexity, or greatest curvature, is very thick; their concavity, or smaller curvature, very thin, and something like the edge of a sickle. They lie on the two upper surfaces of the head of the *Tibia*; each cartilage is broad enough to cover about two thirds of the surface of the *Tibia* on which it lies, leaving one third bare in the middle; their under sides are flat, their upper sides hollow, and, together with the middle portions of the surfaces of the head of the *Tibia*, they form cavities proportioned to the convexity of the condyles of the os femoris. *Winslow*'s Anatomy, p. 128.

Ligaments of the TIBIA. This bone is connected to the os femoris by several ligaments, two lateral, one posterior, two middle, and one capsular. The innermost and broadest of the two lateral ones is fixed pretty low down on the inner side of the superior part of the *Tibia*. The external, which is narrower and thicker than the former, is fixed partly in the *Tibia*, immediately above the fibula, and partly in the upper extremity of the fibula; both these ligaments lie a little behind the middle of the articulation. The posterior ligament is fixed by several expansions in the posterior part of the head of the *Tibia*. One of the crucial ones is fixed by one end to the internal superficial impression in the notch of the os femoris, and by the other, to the notch in the head of the *Tibia*: The other is fixed by one end to the external impression in the notch of the os femoris, and by the other between the anterior portions of the superior surfaces of the head of the *Tibia*. The cornua of the semilunar cartilages degenerate into ligaments, short and strong, by which they are fastened, and communicate by some small portions with the crucial ligaments: They have likewise a common ligament, which like an arch runs transversely between their anterior convexities, to the tuberosity or spine of the *Tibia*. The patella is fastened also by a strong ligament; this runs directly down from the apex of the patella; and, beside this, it has several small lateral ligaments fixed in the lower part of its edge on each side, and inserted anteriorly and a little laterally in the edge of the head of the *Tibia*.

The capsular ligament is fixed round the edge of the head of the *Tibia*, and in the edge of the patella. The crucial ligaments, and those of the semilunar cartilages, are inclosed in this capsule; but the lateral and posterior ligaments, and those of the patella, lie without it. The capsule is also joined to a considerable portion of the circumference of the semilunar cartilages, and is strengthened by many ligamentary fibres. Its inside is smooth, and shining; and where it is not covered with tendons, is very thin. There is likewise a very thin ligament, fixed by one end to the lower part of the cartilaginous side of the patella, and by the other to the anterior part of the great notch between the condyles and the os femoris. The use of which seems to be, to prevent the articular fat from being compressed in the motions of the knee. *Winslow*'s Anatomy, p. 129.

TIBIÆ *Quintus*, in anatomy, a name given by the old authors to a muscle called the *biceps cruris* by Albinus and Winslow, and the rest of the moderns.

TIBIALIA, among the Romans, a kind of swaths with which they used to cover their legs. *Pitisc.* in voc.

TIBIALIS (*Cycl.*)—TIBIALIS *Gracilis*, a muscle of the leg, called also *plantaris*. It is a small pyriform muscle, situated obliquely in the ham, below the external condyle of the os femoris, between the poplitæus, and external gastrocnemius; and its tendon which is long, flat, and very small, runs down on the side of the gastrocnemius internus all the way to the heel. The fleshy body, which is no more than about two inches in length and one in breadth, is fixed by a short flat tendon above the outer edge of the exterior condyle of the os femoris; from thence it runs obliquely over the edge of the poplitæus, and terminates in a very small, but long flat tendon. This tendon runs between the body of the gastrocnemius externus and soleus all the way to the inner edge of the upper part of the tendo achillis, and from thence continuing

its course downward, it joins this tendon, and is inserted, together with it, in the outside of the posterior part of the os calcis, without communicating with the aponeurosis plantaris. Sometimes this muscle is wanting, and in some subjects it is situated lower down. *Winslow*'s Anatomy, p. 220.

TIBIALIS *Anticus*, a long muscle, fleshy at the upper part, and tendinous at the lower, situated at the fore-side of the legs, between the *Tibia* and the extensor digitorum pedis longus. It is fixed above by fleshy fibres in the upper third part of the external labium of the crista tibiæ, and of the inside of the aponeurosis tibialis, or of that ligamentary expansion which goes between the crista tibiæ, and the anterior angle of the fibula. It is likewise fixed obliquely in the upper two thirds of the outside of the tibia, or that next the fibula. From thence it runs down, and ends in a tendon, which first passes through a ring of the common annular ligament, and then through another separate ring, situated lower down; afterwards the tendon is fixed, partly in the upper and inner part of the os cuboides, and partly in the inside of the first bone of the metatarsus. *Winslow*'s Anatomy, p. 217.

TIBIALIS *Posticus*, a long fleshy penniform muscle, broader above than below, situated between the tibia and fibula, on the backside of the leg, and covered by the extensor digitorum longus. It is fixed above by fleshy fibres, immediately under the articulation of the tibia and fibula, to the nearest part of those two bones, chiefly to the tibia, reaching to the lateral parts of that bone above the interosseous ligament, which is here wanting. From thence its insertion is extended below the oblique line or impression in the tibia, over all the neighbouring part of the interosseous ligament, and through more than the upper half of the internal angle of the fibula. Thro' all this space it is fleshy and penniform, and is covered by the extensor digitorum longus. After this, it forms a tendon which runs down below the inner malleolus through a cartilaginous groove, and an annular ligament, and is inserted in the tuberosity of the lower part of the os schaphoides. *Winslow*'s Anatomy, p. 220.

TIBICEN, in zoology, a fish of the cuculus kind, called by many authors, *lyra*, or the *harp-fish*; and in some parts of England, the *piper*.

The head of this fish runs out into two broad horns, which are serrated, or beset with a sort of teeth, or small spines, all along their edges, which is its principal distinction from the hirundo or swallow-fish. Above the gill-fins it has on each side a long and sharp spine. The forehead is elevated into a sort of eyebrows over the eyes; and at the angles of these there are small and short spines; these are crooked; and the spines on the back of this species are longer than in any other of the cuculi. The side lines feel but very little rough to the touch, and the forehead between the eyes is not hollowed as in the other cuculi. The whole head is covered with a bony crust, which runs into two horns or spines behind. It has three fingers or filaments on each side, from the roots of the gill-fins; and its jaws are rough like files, but have no distinct teeth. The tail-fin, and the middle of the back in this fish are red. It is caught in the Mediterranean, and in some other seas. In our county of Cornwal, it is not unfrequently caught about the shores, and from the noise it makes when taken out of the water, is called the *piper*. *Ray*'s Ichthyography, p. 282. *Willughby*'s Hist. Pisc. p. 282.

TIBURO, in zoology, a fish very badly and falsely described by several authors, and proving, on a strict enquiry, to be no other than the lamia or white shark. *Willughby*'s Hist. Pisc. p. 49. See the article LAMIA.

TICK, in the manege, a habit that some horses take of pressing their teeth against the manger, or all along the halter or collar, as if they would bite it.

TICKLISH, in the manege. A horse is said to be *ticklish* that is too tender upon the spur, and too sensible, that does not freely fly the spurs, but in some measure resists them, throwing himself up, when they come near and prick his skin. A *ticklish* horse has somewhat of the ramingues, *i. e.* the kickers against the spurs; but with this difference, that the latter put back, leap and kick, and yerk out behind, in disobeying the spurs; whereas a *ticklish* horse only resists for some time, and afterwards obeys, and goes much better, through the fear of a vigorous ham, when he finds the horseman stretch his leg, than he does upon being actually pricked.

TIDE (*Cycl.*)—In the Philosophical Transactions, N°. 4. we have an account of an extraordinary *Tide* near the western isles of Scotland. For some days one flood and ebb run twelve hours eastward, and the other twelve hours westward, till four days before the new and full moon, and then they resume their ordinary regular course as before, running east during the six hours of flood, and west during the six of ebb.

There is another uncommon irregularity in these *Tides*. Between the vernal and autumnal equinoxes, the course of irregular *Tides* about the quarter moons is to run all day, that is, twelve hours eastward; and all night, for twelve hours more, westward. But during the other six months, from the autumnal to the vernal equinox, the current runs all day westward, and all night eastward.

TIES, aboard a ship, are those ropes by which the yards do hang; and, when the halliards are strained to hoise the yards, these *Ties* carry them up.

TIFACOUM, a word used by some of the chemical writers to express quicksilver.

TIFATUM, a word used by some of the chemical writers to express sulphur.

TIFFE *de Mer*, in natural history, a name given by Count Marsigli to a species of sea plant, commonly but erroneously reckoned among the spunges, and called by authors, a *branched spunge*. This author has called it by this name from its resemblance to the heads of the *typha palustris*, or cat's tail, when ripe in the month of September.

The spunges must be of a lax and cavernous texture; but this plant is smooth and firm, and has no inequalities on its surface, excepting a few short hairs, which give it a velvety look, when first taken out of the water. It is a very elegant and beautiful plant; it grows to two foot in height, and is very elegantly branched. It grows on rocks and stones, and, when first taken out of the sea, is full of a viscous water, as yellow as the yolk of an egg; but when this water is pressed out, and the plant comes to dry, it loses its yellow, and becomes of a dusky brown colour. It is very tough and firm while in the water, but when dry it usually breaks of itself into little pieces, and may be crumbled to powder between the fingers. This is a very strong proof, among others, of its not being of the nature of the spunge.

When viewed by the microscope, the whole surface is found to be covered with extremely fine and slender hairs; and, amongst these, there are an infinity of little apertures, thro' which the sea-water makes its way, for the nourishment of the plant. When a branch of it is cut transversely, there are seen a number of long and fine canals, by means of which the water, received at these superficial apertures, is conveyed to the whole substance of the plant; for these plants are all root, and imbibe their nourishment at every pore. *Marsig.* Hist. de la Mer, p. 82.

TIGEGUACU, in zoology, the name of a small Brasilian bird, of the size of a sparrow, and with a ridged and triangular bill, in which it resembles the moucherolle. Its eyes are of a fine blue, and its legs and feet yellow. It is all over of a deep black, but that it has a large blood-red spot on the top of its head. Its tail is short and black. *Marggrave*'s Hist. Brasil.

TIGER, *Tigris*, in zoology. See the article TIGRIS.

TIGH, in our old writers, a close or inclosure mentioned in antient charters, and is still used in Kent in the same sense. Chart. Eccles. Cant. *Blount*.

TIGILLUM, a word used by some chemists to express the tile with which they cover the mouth of their crucibles; and, by others, for the crucible itself. See the article TILE.

TIGRIS, the *Tyger*, or *Tiger*, in the Linnæan system of zoology, makes a distinct genus of the quadruped class; the characters of which are, that it has four paps placed near the navel, and feet adapted to climbing. The author takes in the panther to this genus, and distinguishes the *Tiger* by the name *Tigris maculis oblongis*, and the panther by that of *Tigris maculis orbiculatis*. *Linnæi* System. Naturæ, p. 35.

The *Tiger* has its name from its supposed swiftness, and has been described by almost all authors as one of the swiftest of all the wild carnivorous animals; but this has been wholly contradicted by such authors as have seen the creature, who all declare that it is a slow and sluggish animal, and is unable to overtake a man, or almost any animal that has an opportunity of running away from it. It will give two or three large leaps; but if it do not seize its prey in these, is but ill qualified to catch it afterwards. *Ray*, Syn. Quad. p. 165.

It exceeds the lion in size, and is of an unconquerable fierceness. It agrees with the panther in the variegation of its colours, but differs in the disposition of them; for in the panther the colours are disposed in round spots or eyes, and in the *Tyger* they are disposed in long streaks.

Marggrave describes three species of American *Tygers*, the first called *jaguera* by the natives, and by the Portuguese *onça*; the second distinguished by the natives by the name *jaguarete*, but called by the Portuguese by the same name with the other; the third called by the Indians *cugua-cuarana*, and by the Portuguese, the *Tyger*. But the two first seeming to be the same with what we know by the name of the *ounce*, and having round, not long variegations, seem properly of the panther, not of the *Tyger* kind.

It were much to be wished that the antients had left us more certain marks, and fuller descriptions of the *Tyger* than they have.

The *Tyger* is found in the East Indies, in many parts of Asia, and in America: But there seems some difference in species between the Asiatic and American *Tygers*, and possibly fuller observation may prove, that the Asiatic are swift, as the antients have described them, and the American ones, of the slowness of which we have accounts, may be a different species.

The manner of carrying off the young brood of this animal is described by Pliny as follows. The Hircanians and Indians bring up the *Tyger*, says he, an animal of a dreadful swiftness, which

which is moſt put to the proof when going to be taken. The whole brood, which is always very numerous, is carried off upon a horſe, as ſwift as poſſible, and often removed to a freſh one. When the mother *Tyger* finds the neſt empty, and the brood gone, for the males take no care of them, ſhe traces the ſcent with furious ſpeed; and when ſhe is arrived within hearing of the perſon who is carrying off her young, he throws down one of them; this ſhe takes up in her mouth, and, as if made more ſwift by her load, carries it back, and then returning, is treated in the ſame manner till the perſon gets on board a ſhip, and leaves her to vent her rage on the ſhore. Vid. *Pitiſc.* Lex. Ant. in voc. *Plin.* Nat. Hiſt. l. 8. c. 18.

TIHOL, in natural hiſtory, a name given by the people of the Philippine Iſlands to a ſpecies of crane very frequent among them, and remarkable for its ſize, being taller than a man, when it ſtands erect, and holds up its neck. They call it alſo ſometimes *tipul.*

TIJEGUACU-*Paroara*, in zoology, the name of a Braſilian bird, of the ſize of a lark. It has a ſhort and thick beak, brown above, and whitiſh below. Its head, throat, ſides, and the lower part of its neck, are of a fine yellow, variegated with red in the female, and all over of a perfect blood-red in the male. The upper part of the neck, and the whole back, are grey, with a mixture of brown; the wings are brown, tipped with white; the tail is of the ſame colour; and the ſides of the neck, the breaſt, belly, and thighs, are white. *Marggrave*'s Hiſt. Braſil.

TIJEPIRANGA, in zoology, the name of a Braſilian bird of the ſparrow kind. It is a little larger than the lark. Its whole body, neck, and head, are of a very fine red or blood colour, and its wings and tail black.

There is another ſpecies alſo of this bird, which is of the ſize of a ſparrow, and is of bluiſh grey on the back, white on the belly, and of a ſea-green on the wings. The legs of this are of a pale grey. *Marggrave*'s Hiſt. Braſil.

TIKE, the Zetland name for an otter, of which there are many to be found about that iſland. Phil. Tranſ. N°. 473. Sect. 8.

TILE, or TYLE, (*Cycl.*) in aſſaying, a ſmall flat piece of dried earth, uſed to cover the veſſels in which metals are in fuſion.

Theſe are made of a mixture of clay and ſand, or powder of flints, or broken crucibles, made into a paſte, and ſpread thin with a rolling-pin, on a table, or flat ſtone. From theſe cakes or plates, pieces are to be cut with a knife, to the ſhape and ſize of the mouths of the veſſels to be cloſed. It is beſt then to pare away the borders of the under ſurface of the piece thus cut off, that this ſurface may immediately touch all the way the edge of the mouth of the veſſel, leaving a prominent rim, by which means the *Tile* ſits cloſe upon the veſſel, and is not ſo eaſily diſplaced by accidents, as a touch of the poker, or of the coals put on to mend the fire, as it otherwiſe would be. Finally, put on the middle of the outer ſurface a ſmall bit of the ſame matter, which ſerves as a kind of handle, by means of which it may be conveniently managed by the tongs, and eaſily taken off and put on again at pleaſure. *Cramer*, Art. Aſſ. p. 66.

TILIA, the *Lime-Tree*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the roſaceous kind, and is compoſed of ſeveral petals, arranged in a circular form. The piſtil ariſes from the cup, and finally becomes an unicapſular huſk, containing oblong ſeeds.

The ſpecies of *Lime*, enumerated by Mr. Tournefort, are theſe: 1. The large-leaved common *lime.* 2. The common *Lime*, with ſmaller leaves. And 3. The hairy-leaved *Lime*, with red twigs and ſquare fruit. *Tourn.* Inſt. p. 611. See the article LIME-*Tree.*

Lime-tree flowers are eſteemed cephalic and cordial; they are alſo recommended in paralytic and nervous diſorders of all kinds.

TILLS, a name given by our farmers to the lentil, a kind of pulſe propagated in ſome parts of the kingdom; they are the ſmalleſt of all pulſe. They require but an ordinary ground, but they produce a vaſt quantity, tho' they lie in a ſmall compaſs. They make a fine ſweet fodder, and are the beſt of all things of this kind for calves, or any other young cattle. They are alſo the beſt of all ſorts of food for pigeons. *Mortimer*'s Huſbandry.

TILLÆA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants, the characters of which are theſe: The calyx is a flat perianthium, divided into three large oval ſegments. The flower is compoſed of three flat, oval, pointed petals, ſmaller than the ſegments of the cup. The ſtamina are three ſimple filaments, ſhorter than the cup. The antheræ are ſmall. The piſtillum has three germina. The ſtyles are three, and ſimple. The ſtigmata are obtuſe. The fruit is three long pointed capſules, of the ſame length with the flower, bent back, and ſplitting open longitudinally in their upper part. The ſeeds are of an oval figure; and two are contained in each of theſe capſules. *Linnæi* Gen. Plant. p. 36.

TILLAGE. The term *Tillage*, in its proper ſenſe, ſignifies the opening, breaking, and dividing the ground by the ſpade, the plough, the hoe, or other inſtruments which divide it by attrition, as the addition of dung does by fermentation.

Dung is only to be had in a limited quantity, and that in moſt places, except in the neighbourhood of great towns, too ſmall a quantity for the huſbandman's occaſions; but *Tillage* is in the power of the workman in every degree; and by this the field of ſubterranean paſture for the plants may be enlarged almoſt without limitation. Though the external ſurface is always confined to the ſame narrow bounds, *Tillage* may extend the earth's internal ſuperficies, in proportion to the diviſion of its parts; and as diviſion is infinite, ſo may alſo that extenſion of the ſuperficies be, which is the conſequence and effect of it.

Every time the earth is broken by any ſort of *Tillage* or diviſion, there muſt ariſe ſome new ſuperficies of the broken parts, which never has been open before; for when the parts of the earth are once united and incorporated together, 'tis morally impoſſible that they, or any of them, ſhould be broken again only in the ſame places; for, to do that, ſuch parts muſt have again the ſame numerical figures and dimenſions they had before that breaking, which, it is eaſy to ſee, will never happen.

Although the internal ſuperficies may have been drained by a preceding crop, and the next plowing may move many of the before divided parts, without new breaking them, yet ſuch as are new broken have, at ſuch places where they are broken, a new ſuperficies, which never was, or never exiſted before.

Tillage, as well as dung, is beneficial to all ſorts of land. Light land being naturally hollow, has larger pores, which are the occaſion of its lightneſs: This, when it is by any means ſufficiently divided, the parts being brought nearer together, becomes, for a time, bulk for bulk heavier; that is, the ſame quantity of it is made to lie in leſs room, and ſo it is made to partake of the nature and benefit of a ſtrong and firm land; that is, it will keep out too much heat and cold, and retain the roots of plants much more ſteadily than it could do before that *Tillage.*

The ſtrong and tough land being naturally leſs porous than it ought to be, is made for a time lighter, as well as richer, by a good diviſion: The ſeparation of its parts makes it more porous, and cauſes it to take up more room than it does in its natural ſtate, and then it partakes of the natural advantages of a lighter land. When ſtrong land is ploughed, but not ſufficiently, ſo that its parts are left groſs, it is ſaid by the farmers to be rough; in this caſe it has not the proper benefit of *Tillage*; for its pores and interſtices are left too large, and it has all the inconveniencies of a hollow land that is untilled. When the light land is ploughed but once, that is not ſufficient to diminiſh its natural hollowneſs or pores; and, for want of more *Tillage*, the parts into which it is divided by that once ploughing, remain too large, and conſequently the artificial pores are large alſo, and, in that reſpect, they and the illtilled ſtrong land are alike.

Light land having naturally leſs internal ſuperficies than any other kind, ſeems to require more *Tillage* or dung to enrich it: As when the poor hollow thin downs have their upper part, which is the beſt, burnt, whereby all, except a caput mortuum, is carried away; yet the ſalts of this ſpread upon that barren land, which is unburnt, divide it into ſuch very minute parts, that their paſture will nouriſh two or three very good crops of corn. But then the plough, even with a conſiderable quantity of dung, is never able to make another diviſion equal to that which thoſe ſalts had done; and therefore, after theſe two or three crops, the land always remains barren. Artificial pores cannot be two ſmall, becauſe the roots of plants can the more eaſily enter the ſoil that has them; quite contrary to natural pores; for theſe may be, and generally are, too ſmall and too hard for the entrance of all weak roots, and for the free entrance even of ſtrong roots. Inſufficient *Tillage* leaves ſtrong land with its natural pores too ſmall, and its artificial ones too large; and it leaves light land, with its natural and artificial pores both too large. Pores which are too ſmall, in hard ground, will not permit roots eaſily to enter them; and pores which are too large in any ſort of land, can be of little other uſe to the roots of plants, but only to give them paſſage into other pores that are more proper for them; and if in any place they lie more open than they ought to the air, they are dried up and ſpoiled before they reach them.

The fine fibrous roots are the only parts of a plant which take in the nouriſhment, the larger part of the roots ſerving only to receive it of them, and convey it to the plant; and theſe fine and ſmall fibrous roots can take in no nouriſhment from any part of the earth, unleſs they are in contact with it, and preſs againſt the ſuperficies: This is the caſe in the ſmall pores in the earth; but by no means in large ones; for a fibrous root can never be compreſſed againſt the ſides of a cavity, whoſe diameter is much greater than its own, as is the caſe in all theſe large pores. The ſurfaces of great clods form declivities, which have large cavities at the bottom; theſe ſerve to receive and convey what rain and dew bring too quickly downward below the ploughed part.

The firſt and ſecond ploughing of land with the common plough, ſcarce deſerve the name of *Tillage*; they rather prepare

pare the land for *Tillage*; the third, fourth, and every subsequent ploughing, are of infinitely more advantage to the ground, and are done at a much smaller expence; but the last ploughings will be most advantageously performed in the manner of hoeings. See the article HOEING.

The finer any land is made by *Tillage*, the richer it will become, and the more plants it will maintain; and it has been frequently observed, that in a large field, where at some time one part of the ground has been better tilled than the rest, that part of the ground has produced the best crops, and been easily distinguished by it from the rest of the field, even six or seven crops after the time of the particular good *Tillage*. A piece of ground being once made finer than the rest, will a long time shew the advantage of it; because the dews have more power to enrich it, they penetrating farther than the superficies, whereto the roots are able to enter. The fine parts of the earth are impregnated throughout their whole substance with some of the riches carried in by the dews, and there reposited until, by *Tillage*, the inside of those fine parts become superficies; and as the coro drains them, they are again supplied as before; but the rough large parts cannot have that benefit, and the dews not penetrating but to their surface, they remain poor. The experiments mentioned by Mr. Evelyn prove this beyond contest. Take of the most barren earth you can hod, powder it well, and expose it abroad for a year, incessantly agitating it, and after this, without any other management, this earth will be the most fertile that can be conceived, and will readily receive any plant from the farthest Indies: All vegetables will prosper and flourish in this once barren earth, and bear their fruit as kindly with us, under a due degree of artificial heat, as in their native climates.

The artificial dust will entertain plants which refuse dung and other violent applications, and has a more nutritive power than any artificial dung or compost whatsoever: And by this pulverising and exposing, the very nature of a soil may be changed, and the toughest clay made as light and friable as common light earth, and as fit for the nourishment of the tenderest plants as any other; though, in its natural condition, its pores were too small to give way to their tender roots, and had no communication one with another.

This is a sort of improvement of land that cannot be practised in the large way, in fields, &c. but as it only consists in dividing and breaking the particles of earth, and exposing them thus broken to the air, it is plain that common *Tillage* approaches more or less to it, as more or less labour is employed; and the experiment proves, that the farmer need never fear bestowing too much *Tillage* on any sort of ground.

It is without dispute, that what was one cubical foot of the original barren earth, and had in that state only six cubical feet in superficies, has after this powdering more than a thousand cubic feet of superficies in its internal parts. The very poorest land, and the very richest, in their natural state, do not differ so much as one, and twenty; that is, a cubic foot of the richest land in the world will not produce more vegetables than twenty foot of the poorest; and as, in this method of pulverising, the ground is made greatly more than twenty times richer than it was before, it is a necessary consequence that any poor land may, by proper *Tillage*, be made richer than the best land in the world naturally is.

There is also another very great advantage, when a soil has a large internal superficies in a small compass, as is always the case after much *Tilling*; which is this, that the roots of plants in it are then better supplied with nourishment; their food being nearer to them on all sides, and more within reach than it can be when the soil is less fine, as in common *Tillage*, and the roots must extend much farther in the one than in the other, in order to reach an equal quantity of nourishment: They must range and fill perhaps twenty times more space, in order to the coming in the way of an equal quantity of food. Hard ground makes too great a resistance to the passage of roots, and air makes too small a pressure upon their superficies; in water they have a free passage to the utmost of their extent, and have every where an equal, proper, and even pressure; and in light and fine earths, such as those divided by an equal and careful *Tillage*, they have much the same free passage and even pressure as in water.

The general custom of farmers is to leave off *Tillage* just when they have brought their lands into such a condition, that *Tillate* would be of vast advantage to them. They usually suppose the soil to be fine enough, when, with the help of harrows, they can cover the seed, and afterwards with a roller they break the clods, to the end that if a crop succeed, they may be able to mow it, without being hindered by these clods. *Tull*'s Horsehoing Husbandry, p. 24.

TILMUS, a term used by some of the medical writers to express the effect of a sort of delirium, in which people pull the bedclothes, or pick out threads from the sheets. This is usually esteemed a dangerous symptom.

TIMBER (*Cycl.*)—The uses of *Timber* are so many, and so great, that the procuring a sufficient supply of it, extremely well deserves the care of every state; as it must be a great disadvantage to it to be obliged to have recourse to its neighbours, and purchase at a very considerable and continually renewed expence, what might, by an easy œconomy, be sufficiently supplied at home.

This œconomy, however, must be applied in time; for our natural indolence, our love to reap the advantages of every thing ourselves, and our little care for posterity, give great room to fear succeeding ages will want wood both for private and public exigencies. All our arts should be employed on this subject, with two views, the one to preserve and cherish our growing wood, the other to renew the trees which have been and are continually cut down.

The quantity of acorns that the oak bears, has made many people suppose, that nature has taken care for a renewal for us, and that of this vast quantity of seeds which annually fall, there will be always an over-sufficient supply of young trees, which will grow up in the place of the old ones: But experience proves, that this is by no means the case. The greater number of these fallen acorns are devoured by a number of different animals, for whose nourishment nature has provided that abundance of them: And of those which escape this fate, we are to consider how few can come to good, from the natural accidents they are unavoidably exposed to; they fall on a covered ground, where dead leaves, and decayed parts of branches of trees, usually prevent their touching the earth, into which they are to shoot; or, if they can shoot here, it is merely from the surface, where they are, in their slow growth, liable, while very tender, to all the inclemencies of frosts; and add to this, that it is very difficult for such tender plants as the young seedlings of these, to find room for growth or nourishment among the every way spreading roots of other trees; and the continual shade and want of free air, must render them very weakly and irregular in their growth, even supposing them to get over all the other difficulties.

It is very certain, that *Timber-trees* of oak are frequently met with among the underwood of forests; but we shall always find this to be the case, not in the close places, but in certain spots where there has been a vacancy or opening; and that usually where there are not, nor have at any time been, oaks in the neighbourhood of the spot. The acorns that fall from the oaks usually come to nothing, from the before-mentioned accidents; and these trees which grow at distances, are owing to the acorns brought thither by birds, and accidentally dropped there. This is an instance familiarly verified, by observing, that there are frequently little bushes near woods, which, though of white-thorn or other trees, are usually surrounded and ornamented with young oaks; the jays and the like granivorous birds are the authors of this crop; for, bringing the acorns from the adjoining woods, to eat under these bushes, they drop many by the way, which they do not trouble themselves to look for on the ground, and which having here a freer ground to strike root into, and an open air to grow in, seldom fail of coming to good, unless destroyed while young.

In order to the preserving our growing *Timber-trees*, it would be a very useful law, that all who cut down any number of oaks, should also leave a given number in good condition for after-cutting; and that no *Timber* should be cut down, but at a proper age, in regard to the nature of the soil; since it is certain, that trees grow to their perfection at very different periods of time, in proportion to the depth of soil they have to grow in; and that as it is, on the one hand, not for the interest of the state to suffer trees to be cut till at their perfection for size and soundness, so, after they are arrived at that perfection, it is equally certain, that they gradually decay.

The quality of the soil the tree stands in, may be necessary to be observed to this purpose; but the quantity or depth of it is the great subject of enquiry; and a great number of observations have proved, that the proper season for cutting oaks in a soil of two foot and a half deep, is at fifty years old; those which stand in a soil of three foot and a half deep, should not be cut down before seventy years; and those which stand in a soil of four foot and a half deep, or more than that, will encrease in goodness and in size till they are an hundred years old: And observation has proved, that after these several periods, the trees begin to decay.

This seems the best rule to establish, in regard to the common soils; but those which grow in a lighter or more sandy soil, may have their periods changed from these to forty, to sixty, and to eighty years at the greatest depth; and after these times it is always best to fell the wood meant for public service, whether then wanted or not, since it is much better to keep it in public magazines, than to leave it to be daily decaying.

Heaths, and other uncultivated places, where there is no regular growth of wood; but where fern, and useless plants alone seem to flourish, usually afford also some straggling trees of the oak. These probably have had their origin from acorns dropped by birds; but these seldom grow tall or regular; since, not having been defended from the injuries of cattle, they are usually browsed on, and stunted while young, and so become crooked and short-trunked, or pollard trees. These, though not of such value as the more regular oaks, yet deserve care, both with respect to their preservation and felling; since they afford a number of trees naturally bent, and formed for many parts of ship-building.

The little care usually taken of these trees, though on this occasion

cafion of great value, feems to threaten a general lofs of them; but as trees, thus naturally crooked and bent, are of value, it is a laudable attempt to try at the finding a regular method of producing fuch; and this is eafily practicable, by following the fame methods by which thefe wild ones become fo. They wholly owe their figure to the cattle's biting off their tops while young, and afterwards biting off again the tops of the fhoots from the firft wound. In this manner, if a number of young trees, fet apart for the experiment, have their tops cut off at two, four, fix, eight, ten, and twelve feet from the ground, and four years afterwards the fhoots from thefe ftunted tops are again cut in the fame manner, the trees will be found afterwards to grow up in all the irregularly crooked figures that can be conceived, and by this means a fupply of naturally crooked wood may be raifed for all the occafions of fhip-building, with infinitely greater eafe and more certainty than by the method propofed by fome, of bending them down with weights tied to their tops while young.

As to the fupply of young wood in the place of what is cut down, there are fome circumftances which have not had the attention paid to them which they deferve. The fpring frofts, which come on at a time when the fhoots, by which nature is to raife the fupply for what is cut down, are juft preparing to grow, are of prodigious injury, and do not lefs mifchief to thefe than to the young fhoots of garden plants, though the diftant hope of the fucceffion to the proprietor, and ufually alfo the diftance of place, and want of repeated obfervation, occafions its not being perceived. This, however, may, in a great meafure, be guarded againft. Frequent experiments, and repeated obfervations, prove, that the mifchief done by thefe frofts, affect in a much greater degree thofe fhoots which are expofed to the fouth, than thofe which face the north; and that it is greatly more powerful againft fuch as are wholly expofed to the wind, than againft fuch as are fheltered. Thefe known circumftances may give the hint to a method of faving, at leaft a great part of a wood to be felled, from this deftruction, to its renewal, by the making it a rule to begin cutting down on the north fide; and, as the whole felling is a work of fome years, the ftanding wood of every feafon will defend the young fhoots of the newly cut ftumps the following fpring, not only from the fouth expofure, but will fhelter them alfo from the wind.

Many prudent managers have made fine eftates of their coppice-woods, by regularly felling a certain portion every year, and providing for a renewal of the firft cutting, againft the felling of the laft portion, by proportioning the time of growth to the quantity to be cut every year; and there is great intereft to be made of a true knowledge of the growth of wood in this manner. Whoever obferves the growth of young trees, will find that the fecond year's growth is much more confiderable than that of the firft; the third year is more than that of the fecond, and fo on for many years; the yearly growths of young wood greatly encreafing every feafon up to a certain time or age of the tree, after which the increafe in bulk, by growth, becomes gradually lefs. The great advantage to be made of coppice-wood, would be by knowing this interefting period, and feizing on it, always to cut down the trees juft at that time when they arrived at the end of their quick growth, and fo fetting nature to work with new fhoots, to employ the fame fpeed on enriching again the owner. Regular obfervation and experiment alone can afcertain this happy period; but any man who has much coppice-wood upon his eftate, may affure himfelf of it, by cutting a given quantity every year, for ten years fucceffively, and then carefully reviewing the differences of the yearly produce. Memoirs Acad. Scienc. Ann. 1739.

Strength of TIMBER. The celebrated Monfieur de Buffon has attempted a rational calculation of the ftrength of *Timber*, ufed in building, on the principles of his excellent demonftration of the growth of trees. See the article WOOD.

He has proved that all wood confifts of a feries of woody cones laid in woody beds, all along the tree, and connected by a fort of reticular work of much lefs ftrength than their own fubftance. He infers hence, very juftly, that when there are, in any fpecies of wood, more of thefe cones, which fhew themfelves in fo many concentric circles in a tranfverfe fection of the wood, and confequently more of thefe weaker reticular fubftances which connect them, that wood muft neceffarily be weaker than fuch in which, in an equal thicknefs, there are much fewer of thefe cones, and confequently fewer alfo of thefe weaker inter-fpaces.

If the irregularities of the ftructure of wood were only thefe, it would be eafy to compute, from the ftrength of a ftaff of an inch diameter, of any wood, what would be that of a beam of the fame, of any given fize; but this is by no means the cafe; for the difpofition of the cones, beds, and interfticial matter, is by no means the fame in a large beam, formed by the workman, as in a little branch in its natural ftate of growth.

This is eafily conceived, when we confider that, in order to make a beam of *Timber*, they fquare a branch or part of the tree, or cut off four cylindric pieces from it, of what is called the blea. The heart of the wood lies now in the middle of the beam; this is the firft woody bed, which all the others fucceffively cover, in form of fo many concentric circles: The larger of thefe concentric circles is of the diameter of the whole piece of *Timber* now cut, and the circles, which naturally furrounded this, are now no longer perfect, but form only portions of circles, diminifhing all the way to the ribs of the beam. A beam, thus fquared, is therefore compofed of a cylindric compleat piece of firm and hard wood, and of four angular portions, cut out of a much lefs folid and firm wood. This is the condition of a beam, fquared out of a large arm of a tree, and made nearly of the diameter of that arm; but a beam of like fize, cut out of the trunk of a larger tree, or out of one fide of fuch a trunk, is a very different thing, and is compofed only of the longitudinal fegments of the annual woody beds; and thefe fegments fometimes lie parallel to one of the furfaces of the beam, and fometimes more or lefs inclined to one or the other fide; they are alfo fometimes longer, fometimes fhorter; and fometimes more, fometimes lefs, cut into the woody beds of the trunk of the tree they were cut from, and the beam is confequently more or lefs ftrong accordingly.

There are alfo two pofitions in a beam, the one of which is much ftronger than the other; for thefe fegments of the woody beds of the tree, form fo many parallel flats. If you place the beam in fuch a pofition that thefe planes or flats are vertical, it will refift a much greater force than if they are placed horizontally in the pofition of the beam.

From thefe obfervations, it is eafy to fee how very fallacious the calculations and tables of the ftrength of different kinds of *Timber* muft be, while the authors have formed all their fyftems upon experiments made on pieces of one or two inches in diameter, and have given themfelves no trouble to enquire into either the number or difpofition of the woody beds in thofe pieces, nor the directions in which the feveral beds were found on breaking them. Thefe, however, are extremely neceffary and effential circumftances; nor are thefe the only variations which they have omitted to obferve; there are perhaps others equally neglected in all fuch attempts, and yet equally neceffary to make them of any real ufe. Young wood has always much lefs ftrength than the older, and there is a great difference between the pieces cut out of the foundeft part of the body of a tree, and thofe from the young branches of the fame tree. A piece cut out of the outer part of the trunk of a tree, near the blea, is alfo much weaker than one of equal diameter, cut out of the center or heart of a tree. The different age, and degree of drynefs in wood, makes alfo great differences in its ftrength; for a green branch of a tree is always more tough, and lefs eafily broken, than a dry one: And the time employed in putting wood to the trial, as to its ftrength, is alfo a circumftance very neceffary to be confidered; fince a beam of *Timber*, which will fuftain a certain weight for a few minutes, will not fuftain it perhaps for as many hours; and experiment has proved, that wood will often bear, for a fhort time, a weight it cannot bear for a longer time; a beam having been found to bear a certain weight for one day, and the fame beam afterwards having been broken in fix months time by only two thirds of that weight. It is eafily feen, from thefe confiderations, that all the calculations in which thefe confiderations have been neglected, can be of very little certainty; and that to make fuch as may be certainly depended on, is a work of great difficulty.

As the advantages refulting from fuch calculations are, however, yet greater than the difficulties attending the attempt, this gentleman was encouraged to purfue the enquiry to the utmoft. He caufed certain pieces of wood to be broken by a determinate force, and calculating, according to that, what ought to be the force to break fuch as were much larger; he tried afterwards what was the real force that would break them, and how far his calculations approached to the truth; in this he ever found extremely great differences between calculation and reality; and after many repeated trials, was never able to bring the fact any thing near the calculations. And trying, according to the fame rules, others of greater lengths and thickneffes, in proportion to the ftandard piece, he found the calculations as far faulty as before. The difappointment in thefe attempts determined him, however, to try a compleat courfe of experiments, from which a certain table of the force required to break the different kinds of wood might be eftablifhed, to which both himfelf, and the reft of the world, might refer to upon occafion. And this he executed in the following manner.

He began by choofing in a certain fpot of one of his own woods an hundred oaks, which were all found and lively growing trees, and ftood as near to one another as they conveniently could. This caution was ufed, that the wood might be all of the growth of the fame foil, fince it is well known that the growths of different foils are in the fame fpecies of wood, of very different ftrengths, and miftakes of this kind might have rendered the whole attempt fruitlefs. Thefe oaks were all of the fame fpecies, and were in fize from two foot and a half to five foot round. They were chofen purpofely of different growths, or fizes, that the experiments might be the

more similar to the usual customs of the workmen. For when a carpenter has occasion for a piece of four or five inches square, he does not for this purpose cut a tree that might have furnished a piece of a foot square, because of the expence; and it too often is their custom to use such pieces as have a very large share of the blea on them. Not unfrequently indeed they use also rafters, sawed out of large pieces of *Timber*; but these are, of all others, the very worst; and the use of them in building ought to be prohibited, the small wood being infinitely more advantageous for these purposes.

As the degree of dryness of wood alters its strength very much, and as it is also very difficult to be assured with any degree of certainty, of the degree of drying or seasoning of *Timber*; since two trees cut down at the same time shall often be found to dry very differently, it appeared to this gentleman much more eligible to take wood perfectly green for his trials, than that in any degree dried or seasoned.

The trees were felled one by one, and were carried into a proper place; the day after they were felled the carpenters were employed to square them, and the joiners to take their exact dimensions; and on the day afterwards, the pieces were put to the proof; and the following is the method in which most of the experiments were made. Two strong tressels were taken, of seven inches square, three foot high and three foot long, and strengthened in their middle by a very strong piece of *Timber*. On these two tressels were placed the two extremities of the piece of wood which was to be broken; there were also ready several square iron buckles, or rings, made of round iron work, the largest of which was nine inches wide, and was made of iron of seven inches about; the next was seven inches wide, and the iron it was made of was five inches round, and others of different degrees below these.

The piece of wood destined for the experiment, was passed through these rings; the larger of which served for the thicker pieces, the smaller for the thinner. Every one of these rings had on its upper part and on the inside, a rib nicely filed, of two or three twelfths of an inch broad.

The intent of this was to prevent the ring from inclining one way or other, when in use; and on its under part it had two hooks of iron, of the same thickness with the ring itself; these were placed at such a distance from each other, as to form another ring of about nine inches in diameter, into which there was to be put a key of wood of the same diameter, and of four foot long. This key carried a strong table of fourteen feet long, and six feet broad, which was made of rafters of five inches thick, nicely fitted one to the other, and secured by strong bars of wood. This was suspended to the ring by means of the large wooden key, and served to place the weights on; these consisted of three hundred quarters of stones, which were all numbered, and weighed from twenty-five to two hundred pounds each. These stones were put upon the table, and a heap of stones were placed together as long and wide as the table, and as high as was necessary for the breaking of the piece.

There was always great care used to place the piece and the tressels on a level; and they were then fastened, to prevent their displacing themselves. Eight men were employed continually to fill the table, and began by placing in the center weights, first of two hundred, then of an hundred and fifty, next of a hundred; and so on to twenty-five pounds. Two men placed on a scaffold, suspended in the air by cords, placed the fifty and twenty-five pound weights, which could not have been otherwise done, without danger of the mens being crushed to death; four other men held firm the four corners of the table, that they might not stir; and another, with a long ruler of wood marked how much the piece bent and gave way, as they loaded it with weights; while another marked the time, and wrote down the weight, which was often, twenty, twenty-five, or twenty-seven thousand pounds.

Mr. Buffon caused more than an hundred pieces of wood to be broken in this manner; some regular square beams, others rafters sawn out of large trunks, beside three hundred bars; and this great number was but barely sufficient to give a regular scale of the force and strength of *Timber*, in proportion to its several lengths and thicknesses.

This gentleman observed, that a large piece of wood never broke, without first giving some notice of it; that green wood broke with much more difficulty than such as was dry; and in general, such sort of wood as had a spring, resisted more than such as had none. The blea of the wood, the wood of the branches, that of the top of the tree, and in general all the young wood, is weaker than that which is older.

The strength of wood is not at all proportioned to its size; and a piece which is double or quadruple the thickness of another of the same length, is much more than of twice or four times its strength; as for example, there required not quite four thousand weight to break a piece of *Timber* of ten foot long, and four inches square; and yet there required ten thousand to break a piece of double that measure; and to break one of four times the measure, it required twenty-six thousand weight; that is, to break a piece of ten foot long, and eight inches square.

The same observation is also made good, in regard to the different lengths, as well as the thicknesses. The laws of mechanics would inform us, that a piece of *Timber* of eight foot long, ought to bear just twice the weight of one of sixteen feet. But experiment shews us here also, that the piece of eight foot long carries much more than the double of the other.

The wood which grows quickest, supposing the land the same, is always the strongest: That which has grown more slowly, and the annual circles of which, that is, its several woody cones, are thin and slender, is always weaker than the wood in which they are thick.

The strength of wood is proportionable to its weight; and a piece of wood of the same length and thickness with another, but considerably heavier than another, is found stronger also, and that very nearly in the same proportion. This is a remark of no small consequence; and, as the general weight of wood is easily known, it may save the expence of too much wood in building, as well as the danger from the greater error of using too little.

This accurate observer takes notice, that some may imagine his experiments to be the less conclusive, that the *Timber* he broke was loose at the ends; and that in a wall, or building, it is usually fixed at both ends. But he observes, that the difference of this circumstance is not worth considering, for that the piece fixed in a wall is liable to bend in the middle, before it breaks; and that the fixures have no power to retain the ends, when they are pulled by this force.

This gentleman took no notice of any pieces which had faults, as many of those he tried had, and broke with much less than their proportion of weight; but confined his observations and reasonings only to such pieces as were perfectly sound and firm.

It might be supposed, that so great a number of trials as these, and that on so easy a subject, should have left nothing farther to be done in it; but the author himself willingly acknowledges that there is yet much to be known. The proportion of the longitudinal strength of wood to its transverse, is a subject deserving enquiry; as wood in buildings is often used in very different positions, and where the force acts upon it, not transversely, but longitudinally or obliquely in different directions. Mem. Acad. Scienc. Par. 1740.

Seasoning of TIMBER, a term used by our husbandmen, to express the preparing *Timber* after it is felled, for cutting and working up for use.

As soon as felled, it should be laid up in some dry airy place, but out of the reach of too much wind or sun, which, when in excess, will subject it to crack and fly. It is not to be set upright but laid along, one tree upon another, only with some short blocks between, to give it the better airing, and prevent its becoming mouldy, which will rot the surface, and produce mushrooms on it. Some persons daub the trees all over with cow-dung, which occasions their drying equally, and prevents their cracking, as they are otherwise very apt to do.

Some recommend the burying *Timber* in the earth, as the best of all ways of seasoning it; and others have found it a fine preservative to bury their *Timber* under the wheat in their granaries; but this cannot be made a general practice. In Norway, they season their *deal* planks, by laying them in salt-water for three or four days, when new sawed, and then drying them in the sun; this is found a great advantage to them; but neither this, nor any thing else, can prevent their shrinking.

The seasoning *Timber* by fire is the best way of all, for piles and other pieces that are to stand under the earth, or water. The Venetians first found out this method, and the way they do it in is this; they put the piece to be seasoned into a strong and violent flame, in this they continually turn it round by means of an engine, and take it out when it is every where covered with a black coaly crust; by this means the internal part of the wood is so hardened, that neither earth nor water can damage it of a long time afterwards. This method is practised in many places for seasoning the posts for paling of parks, &c. and has this to recommend it, that in the very oldest ruins we have ever been acquainted with, there have been found many times pieces of charcoal, all of which has been found uninjured, though buried in the earth for ever so many ages. *Mortimer's* Husbandry, V. 2. p. 132.

When *Timber* has been properly felled, and seasoned, by being exposed to a certain degree of air and sun, there is yet a method of preserving it, much better than it could otherwise be, by external applications. When they are wrought and fixed in their places, the rubbing them over with tar or linseed-oil, has been found of great use. The antients, particularly Virgil and Hesiod, advise the smoak-drying of all instruments made of wood, by hanging them up in the chimnies where wood fires are used. The whole benefit arising from this, seems to be the oil of the wood that is burnt, entering into the pores of the other as carried up in the smoak. But it would be a much more cleanly and easy method to apply some oil of this kind at once, and in any quantity that should be judged requisite. *Mortimer's* Husbandry, V. 2. p. 104.

The Dutch, who have *Timber* about their fluices, and other buildings upon the water, more expofed to the injuries of wet and weather than any other that is known; have a way of preferving it, by coating it over with a mixture of pitch and tar, which they fmear over the whole furface; and immediately, while it is moift, they throw on it as much fand and powder of cockle-fhells as it will retain. Thus it is coated over with a rough cruft which will defend it from all kinds of injuries. See the article SULPHUR.

Green *Timber* is apt to fplit and cleave in feveral places, after it is wrought into form. Workmen have different methods of remedying this deformity, for which fee the article CLEFTS.

Felling of TIMBER. See the article FELLING.

Hardening of TIMBER. See the article HARDENING *of Timber*.

TIMBER-*Lode*, in our old writers, a fervice by which tenants were to carry *Timber* from the woods to the lord's houfe. *Blount*.

Meafuring of TIMAER, To meafure round *Timber* without the help of inftruments: let the mean circumference be found in feet, and decimals of a foot; fquare it, multiply this fquare by the decimal 0.079577 and the product by the length. For inftance, let the mean circumference of a tree be 10.3 feet, and the length 24 feet; then $10.3 \times 10.3 \times 0.079577 \times 24 = 202.615$ = the number of cubical feet in the tree. The foundation of this rule is, that, when the circumference of a circle is 1, the area is 0 0795774715, and that the areas of circles are as the fquares of their circumferences. Treat. Pract. Geom. p. 150.

The common way ufed by artificers for meafuring round *Timber*, mentioned in the Cyclopædia, differs much from this rule. One fourth part of the circumference or girt, is by them reckoned the fide of a fquare, whofe area is equal to that of the fection of the tree; they therefore fquare the girt, and then multiply by the length of the tree. According to this method the tree of the laft example, would only be computed at 159,13 cubical feet.

TIME (*Cycl.*)—TIME, in the manege, is fometimes taken for the motion of a horfe, that obferves meafure and juftnefs in performing a manege; and fometimes it fignifies the interval between two of his motions. In the manege of a ftep and a leap, the horfe makes by turns a corvet between two caprioles; and in that cafe the corvet is one *Time* that prepares the horfe for the caprioles.

The *Times* obferved in making a ftop, are nothing but fo many falcades.

TIME alfo fignifies the effect of one of the aids, thus, we fay, a good horfeman difpofes his horfe for the effects of the heel, by beginning with one *Time* of the legs, and never runs precipitately upon his *Times*.

TIMOROSO, in the Italian mufic, intimates that the fong is to be played or fung, in fuch a manner as to exprefs an awe or dread, either to fhew refpect, or to reprefent fear.

TIMOROUS, in the manege. See the articles STARTING, SKITTISH, &c.

TIN (*Cycl.*)—The combinations and feparations of metals, are fubjects that have employed the thoughts of the moft accurate chemifts in all ages; yet new difcoveries are ftill to be made, and in thefe experiments as well as in many others, we are by no means yet arrived at the utmoft perfection.

Mr. Groffe in the memoirs of the academy of fciences of Paris, has delivered a method he had invented of feparating *Tin* from lead or filver.

The advantages arifing from the mixtures of different metals, are very numerous and of many different kinds; to this we owe the metal ufed for bronzes, for bells, for reflecting mirrors ufed in opticks, and a multitude of the like matters; a mixture of this kind makes brafs of copper, a little copper in the fame manner, gives filver a hardnefs that greatly adds to its utility, and gives hardnefs and a more pleafing colour to gold; a little copper or antimony give *Tin* a hardnefs, and render it more fonorous: and a multitude of advantages befides might be enumerated. But there is no lefs neceffity and advantage alfo in the feparating metals, fometimes when they have been joined by art, or are found united by nature: in thefe cafes fometimes both the metals are preferved, fometimes the bafer or lefs valuable is deftroyed.

Of thefe feparations of metals fome are very eafy; lead and mercury are feparated from gold and filver by heat alone, and fo are antimony from gold, or zink from copper. On the other hand there are fome feparations which cannot be effected without great trouble; of this kind are the mixtures of *Tin* with lead and with filver. It is not common to mix filver and *Tin* together on any occafion; but they are fometimes found mixed, and give the refiners great trouble; and even the chemifts, who have often mixt *Tin* with filver to increafe it, have always found it very difficult to feparate it again.

Mr. Groffe happened to be prefent at the melting fome filver, which plainly indicating that it contained fome other metal, in the refining he ordered the workman to examine the lead which he ufed, and found that there was *Tin* among it. The fcoriæ of the metal, which contained with the *Tin* a large quantity of filver, had on thefe occafions been ufed to be fold to the bell-founders, to the great lofs of the proprietor of the metal. Some indeed had advifed different methods of recovering the metal from them, but without fuccefs. It was on thefe fcoriæ that Mr. Groffe tried his experiment; it feemed to him that one great ftep toward the feparation of the filver, was the haftening the calcination of the *Tin*, and with this view he tried a mixture of charcoal, falt-petre, and earth, which he put together into the copel with the fcoriæ. It is eafy to fee that a detonation would happen from this, and this muft greatly add to the force of the fire, in acting upon the fcoriæ, while the ferrugineous matter well known to be contained in the charcoal mixed itfelf with the *Tin*, and muft greatly accelerate its calcination, divide its parts, and give the fire a new action over it. The confequence of this perfectly anfwered expectation, and recovered a large quantity of filver from the fcoriæ, in which the *Tin* had before held it firmly imbodied; repeated experiments proved the truth of this obfervation, and it was found to be eafy by this means at any time to feparate filver from *Tin*, or to purify filver without lofs, by means of lead in which *Tin* has accidentally been embodied. The common method ufed by the plumbers to feparate their folder from old leaden pipes, &c. might feem an eafy way of feparating *Tin* from lead, but this is not truly the cafe; the *Tin* in this inftance not being feparated from the lead, but only a mixture of *Tin* and lead, which had been employed as folder is feparated from fimple lead, which had been foldered with it. The method of making this feparation, is only by melting the folder off from the fimple lead by a fire not ftrong enough to melt the lead itfelf.

The fcoriæ in which *Tin* is mixed with filver, are compofed of *Tin* half calcined, and run into an opake vitrified fubftance, which forms a fort of net-work, in which the filver is confined in extremely fmall particles. If this is thrown into aqua fortis, the whole is diffolved: but then it requires a very ftrong fire to make the *Tin* lofe its metallic form; finally if the whole is finely powdered and then put into this menftruum, the filver only is taken up or diffolved, the *Tin* remaining untouched at the bottom of the veffel.

The fame gentleman found alfo a method of feparating *Tin* from filver, by means of corrofive fublimate of mercury. To conceive the manner in which this feparation is effected, a piece of fine *Tin* need only be caft into a folution of fublimate; in which cafe the acid of the fea-falt is feen to leave the mercury in order to fix upon the *Tin*.

And, according to the fame principle, if fublimate corrofive be added to a mixture of *Tin* and filver, the fame effect is produced, the acid affixes itfelf to the *Tin*, and makes with it a butyrum joviale or butter of *Tin*, the mercury becomes diffipated in the mean time by the action of the fire, and the filver remains pure and alone; but in this experiment, if too much corrofive fublimate be added, there is danger of lofing fome of the filver; fince the abundant acid will prey upon and carry off a part of that metal, making a fort of luna cornea which diffipates itfelf in the air, or if the operation be performed in a clofe veffel, a butyrum lunare.

Gold may alfo be purified from *Tin* in this manner, and in this there is no rifk of lofs, fince the acid which takes up the *Tin* has not the leaft power over that metal: In all thefe proceffes, however, the operator muft avoid the fumes iffuing from the crucible, for they are very dangerous.

Thefe methods of feparating *Tin* from filver are very certain and infallible, but they are too expenfive to be employed in common, and in larger works.

The feparating *Tin* from lead to be employed in the refining of filver is a matter of great importance; and this may be done in the following manner: Melt the lead, and when in fufion throw into it a quantity of filings of iron, then increafe the fire to a confiderable degree, and the furface of the metal will be covered with a fort of fcum, which is no other than the iron and *Tin*. At this time there fhould be a little alkali falt thrown in, and by this means the fcoriæ readily feparate themfelves, and the pure lead remains in form of a regulus at the bottom. The fame method may be ufed to feparate *Tin* from filver in the larger way, but it will be neceffary for this purpofe to add fome lead, fince otherwife the fufion will be very flow and difficult, and the *Tin* will calcine without feparating from the filver. This is a very eafy and very cheap method, and will obviate moft of the mifchiefs which happen to the refiners, of which they would have much lefs frequent reafon to complain, if they nicely examined the lead they were to employ. But if gold or filver be mixed with *Tin*, the fhorteft method in fmall quantities is to calcine the whole very brifkly, and in order to compleat the vitrification and feparation of the *Tin*, to caft in a little glafs of lead, which will immediately join itfelf with it and carry it off from the mafs.

It may feem fingular that iron being one of the hardeft of the metals to melt, and *Tin* being of all the eafieft, they fhould fo readily and eafily unite in thefe experiments; but this feems to be the refult of one of thofe natural and unexpected alliances which accident frequently difcovers to us in bodies. There is one conjecture, however, that may be worthy a place in this refearch, which is, that all *Tin* ore contains a quantity of arfenic, and it is well known that iron very readily mixes with arfenic, and is employed to feparate the arfenic from other ores, and a regulus may be formed of arfenic and iron. It is eafy to fuppofe that *Tin* is in its metalline form, not wholly divefted of the arfenic it contained when in the ore, and if this be allowed,

lowed, it is no wonder that the two metals are eafily brought together by the mediation of that principle. Memoirs Acad. Scienc. Par. 1737.

Mr. Cramer gives the practical rules of feparating filver from *Tin*, thus: Divide one centner of *Tin* into two equal parts; put each of thefe into a feparate teft, and add to each fixteen centners of granulated lead, and one of copper; put the whole under the muffle, and make a very ftrong fire; the *Tin* will be calcined immediately, and will fwim upon the lead. Then diminifh the fire a little, till the afhes of the *Tin* that fwim upon the furface do no longer fparkle; when you fees this, add with a ladle two centners of glafs of lead to each teft, in fuch manner that it may be fpread wide over the whole furface of the rejected calx; the calx will then change its form of powder into that of glafs; then increafe the fire to its higheft degree, ftir up the whole with an iron rod made warm; and when the fcorification is perfected, pour out the mafs into a mould; the fcoriæ being feparated, put both the regulus's into two coppels well heated; and into a third put fixteen centners of lead, and one of the fame copper ufed in the procefs; examine all thefe beads after the coppelling is over; if the two firft weigh exactly alike, 'tis a proof the procefs has been well performed, and fubftracting the weight of the bead, feparated from the third pan, from the joint weight of the other two, the remainder is the weight of the pure filver contained in the quantity of *Tin* which was examined. *Cramer's* Art of Affaying, p. 228.

Tin eafily melts with filver, gold, or copper; but when they are mixt with it in equal or lefs quantity, it renders them extremely brittle. Silver is peculiarly fufceptible of this mifchief, and becomes almoft as brittle as glafs, by the admixture of a very fmall quantity of *Tin*. Much greater quantities of *Tin*, however, in fome metallic maffes, leaves them ftill pliant in fome degree. Ten parts of *Tin*, and one part of copper, melted together, make a mafs more rigid than pure *Tin*, but ftill fomewhat tractable; and it is by this artifice, that veffels and utenfils are made of tin, and yet are found confiderably hard.

If to ten parts of *Tin*, and one part of copper, a little zink or brafs be added, it makes a very fonorous metal, but brittle. This is fometimes the mixture ufed as bell-metal, and cannons are in fome places caft of it. Lead becomes fomewhat more rigid, or lefs ductile than before, by being mixed with *Tin*; but of all the metals it fuffers the leaft by the mixture.

If filings, or thin plates of iron, be made red hot in a crucible, and a double quantity of *Tin* put to them in a great fire, the whole will run into a brittle white regulus, which will yield to the magnet.

The vapours of *Tin* are very noxious to filver, gold, and copper, rendering them all brittle; nay, if only a little *Tin* be put into the fire, in which they are to be melted, they become brittle as foon as red-hot, and will break like glafs under the hammer.

This metal, expofed to the focus of a powerful burning-glafs, melts, and emits a thick white fume, and, if held there a long time, wholly diffipates itfelf in that fume. If, on the contrary, this metal be fufed in a coppel by the fame heat, it fumes confiderably, and its furface becomes covered with a white calx, which greatly rarifies and expands, and there finally appear numbers of cryftalline and bright ftriæ like needles in that calx. If this be continued in the focus on a piece of free-ftone, thefe cryftals ceafe to fume, and remain fixed while the ftone itfelf melts and runs. And in the coppel there is ufually a part of thefe run into a reddifh matter, refembling a fort of enamel. If the calx of *Tin* (that is, *Tin* reduced to a grey powder, by being divefted of a part of its oil in the fire) be expofed to the focus of the burning-glafs, it fumes more than plain *Tin*, and is very foon transformed into cryftalline ftriæ, or needles. And if thefe are again expofed to the fame focus, placed on a piece of charcoal, they readily melt, and again affume the form of common *Tin*. The charcoal, in this cafe, furnifhes to the calx of *Tin* that oily matter which the fire had divefted it of; and it is well known, that if the calx of *Tin* be made red hot in a crucible, and any fatty or inflammable matter be added to it, it immediately refumes the form of *Tin* again; this reduction is wholly upon the fame principle with the other, the oil of charcoal doing in the firft, what the fat does in the laft.

It appears, upon the whole, that *Tin* contains an oily matter, which is eafily driven off by fire, and very eafily received again on the mixture of any fat fubftance; that the earthy matter, which is the bafis of *Tin*, is of a cryftalline nature, and very hard to fufe, fince no common fire can vitrify *Tin* alone; and even the focus of the moft powerful burning-glafs does it but with great difficulty, and imperfectly; this femi-vitrification is what throws the calx into needles, whereas were it perfect, the whole would be one uniform mafs, Mem. Acad. Par. 1709.

TIN, in medicine, though greatly celebrated by the writers of many paft ages, is not much efteemed at prefent. It is faid to be good in convulfions, epilepfies, and the madnefs arifing from the bite of a mad dog. Its preparations are thefe: 1. *Stannum pulverizatum*, or powdered *Tin*. 2. *Sal Jovis*, or falt of *Tin*. 3. *Diaphoreticum Joviale*, or antihectic of Poterius. 4. *Aurum mufivum*, or, as it is commonly called, *mofaicum*, mofaic gold.

The powder of *Tin* is faid to be a good remedy againft worms, particularly of the flat kind, which often elude the force of other medicines. See the article WORM.

TIN is alfo a word ufed by fome of the chemical writers to exprefs fulphur.

TIN *Floors*, a contrivance ufed by our hufbandmen who propagate hops, to dry them after the gathering. The common way of doing this, is either on a hair-cloth on a malt-kiln, or elfe by theooft. See the article OOST.

In both thofe ways, however, the hops fuffer very much; the beft way is by the *Tin floor*. It is thus done: Let a fquare brick room be built, with a door on one fide, and a long fire-place of a foot wide in the middle, reaching almoft acrofs it; let holes be made at the fides of this fire-place, to let out the heat into the room; and at the height of five foot above this let a floor be made of laths of an inch thick, laid lattice-wife. Let this be covered with great plates of double *Tin*, taking care that the joinings of the *Tin* be well foldered, and lie upon the laths, not over the interftices, which may be about four inches wide. Let a row of boards be fitted round the edge of this floor, to keep the hops from falling off, then lay on a covering of hops of a foot thick; then make a fmall fire of charcoal in the mouth of the fire-place, and the hops will dry very quick and very regularly. They may be continually ftirred about while drying, and when enough, a part of the boarded edge of the kiln may be taken down, and the dried parcel thruft out, and a frefh parcel laid on in their place. A very fmall quantity of fuel is fufficient in this way, and any fuel will do, for the fmoke never comes at the hops. There is a very great improvement ftill upon this method of drying hops, ufed by fome people; this is the making a wooden cover, of the fize of the *Tin floor*; this is covered with plates of *Tin* nailed on, and is fufpended over the kiln in fuch a manner, that it may be let down at pleafure, when the lower parts of the hops are dry. This is to be let down within ten inches of their furface, and there it acts as a reverberatory, and drives back the heat on the upper ones, fo that they are dried as foon as the lower ones. Thus all the trouble of turning is faved, and the hops are much better dried than in any other way. *Mortimer's* Hufbandry, p. 186.

TIN *Hatch*, in mining, a term ufed by the people of Cornwall, to exprefs the opening into a *Tin* mine. They alfo call it a *Tin-fhaft*.

They make feveral openings in the fides of the hills where they fufpect veins of ore to be. All thefe, except that which opens on the head of the mine, are called *effay-hatches*; but that which does fo, is made their entrance afterwards, and changes its name to that of the *Tin-hatch*.

TIN *Ore*. The firft procefs toward the feparating the metal from this ore, is the roafting it, which the affayer performs in this manner: Put fix centners of *Tin* ore in coarfe powder in a teft, under a muffle made thoroughly red hot, fhutting firft the veffel for a few minutes, and then opening it. If the fire is pretty ftrong, the volatile part will be feen expelled in a thick white fmoak, fmelling like garlic. When this is over, take out the teft, and when the ore is cold, beat it to powder, and roaft it again in a fomewhat ftronger fire, till it exhales no more arfenic, which may be known by putting upon the teft, when juft taken from the fire, a thick cold plate of iron, which will be covered on its under furface with a fmall whitifh cloud, if the ore yet exhales any arfenic. *Cramer's* Art of Affaying, p. 332.

When the roafting is thus finifhed, the ore may be run into malleable *Tin* in the common manner, as the common lead ore is, only with this caution, that the fire in the operation be carried as foon as poffible to the higheft degree that is neceffary here, and the veffel taken out of the fire, as foon as the operation is judged to be finifhed.

TIN *Plates*, an article of manufacture very common among us, and vulgarly called *Tin*. It is iron plated over with *Tin*. The French call it *fer blanc*, white iron, as we fometimes do in England. It was once known under a diftinct name, *latin*. See the article LATIN.

TINA, a name given by the old medical writers to a bath made of a ftrong decoction of many carminative ingredients, to be ufed in the colic.

TINCA, the *Tench*. See the article TENCH.

TINCA *Marina*, the *Sea-Tench*, in zoology, a name given by fome authors to the common *turdus*, called in Englifh, the *wraffe*. *Willughby's* Hift. Pifc. p. 320. See the article WRASSE.

TINCTURE (*Cycl.*)—A general rule for the properly making light *Tinctures* may be taken from the following bitter. Take half an ounce of Seville orange-peel fhaved thin, half a dram of gentian-root thin fliced, a fcruple of the tops of Roman wormwood, half a dram of cardamum-feeds, and the fame quantity of cochineal, each of them lightly bruifed; put thefe ingredients into a pint of French brandy, let them fteep for one night, and filter the liquor the next morning, and thus you have a fine light bitter.

Thefe

These bitters are of the number of many other substances, where the goodness of a *Tincture* does not more depend upon the choice of the ingredients, than upon the manner of their being infused; for if such be suffered to remain too long in the menstruum, or if heat be used in extracting the *Tincture*, the gross, terrestrial, and nauseous parts of the ingredients will be fetched out, and the *Tincture* will thus be loaded with a heavy indolent matter of little virtue. *Shaw's* Lectures, p. 202.

If however, a greater strength be required in the *Tincture* than can be procured by so slight an infusion, when the ingredients are of this nature the matter should never be suffered to be heated or stand long on the same ingredients, but should be when strained off, poured on fresh ones, and so on till of any strength desired, yet perfectly free from the grosser parts.

Apothecaries usually commit the same error in their finer *Tinctures*, that they do in their cordial waters, saturating the liquor in both cases with the grosser and more useless part of the ingredients: whence the cordial waters of the shops too often abound with a gross heavy oil, and the *Tinctures* with a gross heavy earth, or kind of bituminous matter, instead of the brisk, lively, and invigorating spirit, which alone is the thing required in both cases.

To extract the *Tinctures* of hard, resinous, or gummy bodies, however, requires a different treatment, and must be effected in another manner. See the article Gum-*Lac*.

A great variety of *Tinctures* may be given to common water, and many remarkable things occur in their changes on the addition of common menstruums. Take a large spoonful of the syrup of pomegranate-flowers, mix it with five spoonfuls of water; the mixture will be of a very lively and brilliant red: for a violet colour, take the same quantity of syrup of violets and the same of water. When these *Tinctures* are thus prepared have at hand a vial in which is a small portion of oil of tartar, which will only look like water remaining after the washing of the vial. Pour the red or the violet *Tincture* into this vial, and it immediately becomes a fine grass green. Dissolve the quantity of a walnut of crude sal armoniac in a glass of water, pour all out except three or four drops at the bottom, and pour into this glass the fine red liquor, and it immediately becomes black as ink. In order to change the purple liquor red, only have a small quantity of spirit of vitriol in the bottom of a vial, and pour into this; the violet water it immediately on this becomes of a florid red.

Steep Brasil wood in common water, or in white wine twenty hours, the liquor will then look of the colour of red wine; pour this into a glass washed with vinegar and it becomes of a fine yellow, like sack. If this experiment be made with white wine, the wood and the vinegar make so little alteration in it, that it may be drank afterwards, and the whole process seems a way of turning red port into sack. Into this liquor when yellow, drop a few drops of a *Tincture* of benjamin made in spirit of wine, and it immediately loses its yellow colour and becomes white. Beat some galls to fine powder, and rub the powder on a towel, then put into a bason of water, in which any person is going to wash their hands and face, a small piece of common green vitriol, or copperas, after the person has washed, let them have this towel to wipe on, and the hands and face will be as black as if washed with common writing ink. The copperas in the water and the galls on the towel making real ink where they mix. This does no lasting injury to the skin, but will come off again upon washing with soap. Phil. Trans. N°. 238. p. 88.

Tincture *of Ambergrease*. See the article Amrergrease.

Tincture *of Antimony*, *Tinctura Antimonii*, is thus made; take salt of tartar a pound, antimony half a pound, rectified spirit of wine a quart; reduce the antimony to powder, and mix it with the salt by fusion over a strong fire. When it is cold, powder it, and pour on the spirit of wine; digest them together three or four days in a sand heat, and then filtre off the clear *Tincture* for use. The salt of tartar yields a *Tincture* as well as the antimony. It is a diaphoretic and attenuant.

Tinctura *Antiphthysica*. See Tinctura *Saturnina*.

Tinctura Foetida, the stinking *Tincture*, a form of medicine in the late London Dispensatory prepared in this manner; take assafœtida four ounces, rectified spirit of wine a quart, digest them together for some time, and then strain off and filtre the *Tincture* through paper.

Tinctura *Martis cum Spiritu Salis*, a medicine thus prepared: take filings of iron half a pound, Glauber's spirit of sea-salt three pounds; digest all together without heat, as long as the spirit will work upon the filings; then after the fæces have subsided, pour off the clear liquor, evaporating it to one pound, and adding rectified spirit of wine three pints.

This *Tincture* is good in all the cases, in which the *sal martis* is so. See the article Sal *Martis*.

Tinctura Sacra, a *Tincture* of aloes, called also *hiera picra*.

The late London dispensatory have ordered this to be made of only eight ounces of aloes, and two ounces of winter's bark, powdered and put into five quarts of white wine, which is to be shook often, and kept in fusion a week or more without heat, and then strained off for use. *Pemberton's* Lond. Disp. p. 266.

It is a very good method to mix some clean white sand with this, to prevent the aloes from running together in lumps.

Tincture *of Saffron*. See the article Saffron.

Tinctura Saturnina, the lead *Tincture*, a name given in the late London dispensatory to the *Tincture* before called *Tinctura Antiphthisica*.

It is made of sugar of lead and green vitriol, each two ounces; of rectified spirit a quart. The salts are separately to be reduced to powder and then put into the spirit, then the whole is to stand some days without heat to extract the *Tincture*, and afterwards filtered through paper. *Pemberton's* Lond. Disp. p. 277.

Many persons have found great perplexity in making this *Tincture*, it having at first begun to shew a good colour, but afterwards lost it; this accident is owing to heat usually employed in making the *Tincture*.

This *Tincture* is a powerful styptic, and is often used with good success in hectic fevers, spittings of blood, heat of the kidneys, simple gonorrhœas, fluor albus, and tabes dorsalis.

It was first recommended by Etmuller; who from its effect gave it the name of *Tinctura antiphthysica*, which our college of physicians have changed to that of *Tinctura Saturnina*. We also find it in the pharmacopœa of Edinburgh, and in the best of the foreign ones. Mr. Boyle recommends it, and our most eminent physicians use it; notwithstanding that some authors consider it as a dangerous medicine, on account of its principal ingredient, the *saccharum saturni*, which some call a slow poison. Whether it be so or not when given in substance, there it is certain, that there is a great difference between a corrosive salt so given, and a *Tincture* made of the same, in spirit of wine, and given in small doses, as Dr. Mead observes. Who adds, that in slow hectic fevers attended with a looseness, profuse sweats, and a colliquation of the humours, he reckons two or three drachms, given at different times in cooling liquors every twenty-four hours, to be a convenient dose. But the usual dose is thirty drops in Bristol water, or some temperate or cool julep. See *Acc. of a medical controvers. in the City of Cork*. p. 58, 59.

Tinctura *Sĕnæ*, a form of medicine prescribed in the new London pharmacopœa, and intended to stand in the place of the medicine commonly called elixir salutis, and Daffy's elixir. It is thus made, take stoned raisins sixteen ounces, leaves of sena a pound, carraway seeds an ounce and half, cardamom-seeds half an ounce, proof spirit a gallon; digest all together without heat, and when the *Tincture* is well extracted press off the spirit and filtre it for use. *Pemberton's* Lond. Disp. p. 278.

Tinctura *Styptica*, a form of medicine made with very little trouble and apparatus, and serving to supply the place of that elaborate preparation the *Tincture* of Helvetius; it is prescribed in the late London pharmacopœa, and is to be made by mixing a dram of calcined green vitriol with a quart of French brandy *Tinctured* by the cask, this is to be shook together that the brandy may turn black, and then strained off for use. *Pemberton's* Lond. Disp. p. 280.

Tinctura *Thebaica*, a name now given to the *Tincture* of opium, commonly called *laudanum*.

The method of making this is also much altered, as well as the name in the late London dispensatory, where the saffron being looked on as an useless ingredient is wholly left out, and the medicine ordered to be prepared in the following manner: Take of opium strained two ounces, of cinnamon and cloves each a dram, white wine a pint, infuse without heat a week and then strain off the wine through paper. *Pemberton's* Lond. Disp. p. 266.

Tinctures, in heraldry, a word used to express colours, red, blue, green, and the like.

The writers on heraldry have had great disputes about which of these colours or *Tinctures* are the most honourable. All agree in giving the pre-eminence to the metals gold, and silver that is to the yellow and white colours; as to the others, some esteem them more noble as they approach more to light, that is to whiteness. Upton on this account ranges them thus; azure or blue, gules or red, purpur or purple, vert or green, sable or black; others wholly diffent from this, and prefer those colours most which can be seen at the greatest distance; with these, sables or black is the most honourable or first colour; and they alledge the imperial black eagle, placed in a white field as an instance of this. Leigh prefers the red to the blue, as the red has some alliance to gold, and the blue to silver; the sable is generally preferred to green and purple, by those who give the red and blue the first places: it is in this esteem on account of its strong appearance; and green is preferred to purple, because the latter is but of very late use in heraldry, and is called a new colour.

All the precedence given to *Tinctures* must however be considered with this special proviso, that there is no particular reason for bearing them otherwise in the arms of kingdoms and families. In all coats of arms there should be two colours or *Tinctures*; and it is the general rule that the field should be of a nobler colour than the figures placed upon it:

thus

thus in the arms of Scotland the field is yellow, and the lion placed upon it red: and if the field confifts of two different colours parted by fefs or by pall, then the nobleft colour muft always be in the beft place, as on the upper part, or on the right hand of the fhield; but all thefe rules are to be underftood with this limitation, that there are no other fpecial reafons in the family for the contrary. *Nefbit's* Heraldry, p. 19.

TINEA (*Cycl.*)—TINEA *Campeftris*, the *field moth*, in natural hiftory, the name given by Mr. de Reaumur to a fpecies of infect, which in all refpects refembles the *moth* fo deftructive of cloaths, except in its food; as that feeds upon woollen, and makes its neft or covering of that fubftance; this eats the leaves of trees, and in the fame manner makes itfelf a covering from the fibres and integuments of them.

Their changes are the fame with thofe of the common moth, and performed in the fame manner; they only feem to differ in having a more moift food.

Mr. Reaumur firft obferved thefe on the leaves of the afh. This creature for a great part of its life wants no covering, but like the afcarides making its way through the upper integument of the leaf, it feeds on the parenchyma and juices; at length when it has eat away all the fubftance of the leaf, it bites out a piece from each integument of it, over and under its body, and faftens the edges all round with threads of its own fpinning; thus making a compleat cafe or covering, enabling it to bear the open air. This done, it marches from its place to find another leaf fit to fupply it with more nourifhment: thus it changes place feveral times during its life, and as often changes its covering, which requires but a very little time to make a new.

This creature may eafily be found by the curious fearcher in the fpring; for at that time, if the leaves of the afh are examined, many of them will be found flaccid and as it were dry, and the creature will ufually be found buried among the parenchyma of thefe, between their two integuments. Toward the end of fummer thefe creatures pafs into the chryfalis ftate, and from this, after a fhort ftay, into a fmall fort of moth, which flies about the leaves of the fame tree; and is very beautiful when examined by the microfcope, but is too fmall for obfervation by the naked eye. Thefe of the afh are very common, and there is alfo another kind little lefs fo, which at length changes into a two-winged fly, very fmall but of very great beauty; thefe feed upon the leaves of the willow, and make their cafes of the downy matter which envelops its feeds.

Thefe are fmall animals of this genus; but there are others which are confiderably larger, and which make their coverings of various matters and of different ftructure; they are ufually very rough and rugged, and feem made of any matter that happens to be in the way; fome fpecies ufually make them of pieces of ftraw and particles of chaff, others of fmall twigs of bufhes, others of the dry leaves of the oak, broom, and other plants. One fpecies there is that erodes wood; but it never pierces deep into it, but only eats off a part of the furface to furnifh itfelf with matter for its covering. Several fpecies of thefe alfo are inhabitants of the water in this ftate: thefe form their cafes of various materials, in the choice of which they do not feem at all nice. Some of them make them principally of fand; others take the fragments of water-plants, and the fhells of fmall frefh water fhell-fifh into their work. This cafe makes the fhell, under which they fuffer their change into the nymph-ftate; and as according to the general rule of nature, in regard to the water nymphæ of winged animals, thefe have a neceffity of taking in water at times, one end of this fhell or cafe is never clofed up, but only covered with a reticular clofe work. In this ftate they float upon the furface of the water, till the time of the perfect fly's appearing. There are befide thefe, alfo a fpecies of wall *Tinea*, which have been fuppofed by fome to eat the very ftones and other materials of which the walls they crawl upon are built. This however is an error, for they feed only on the liverworts and other plants which grow upon them, and make their cafes out of the integuments of their leaves, and of the fibres of moffes and other things they find there. There is yet another fpecies of thefe moths feeding on vegetables which differs from all thefe, in that it fpins its covering of a fort of filk, which it produces out of its own entrails in the manner of the filk-worm. Thefe cafes are not made fo fpeedily as the others, but are formed of feveral fcales applied at different times one over another, and refemble a fort of coat of armour. Under the cover of this the creature feeds at large on feveral forts of vegetables, and when it has lived the deftined time in this ftate, it draws its whole body under this covering, faftens up the apertures, and thus defended from injuries paffes into the nymph ftate, and after a proper time is feen iffuing out of that in form of an infect of a middle nature, between the fly and butterfly, called a mufco-papilio.

There is a fpecies of *Tinea* or moth, found in the flowers of the lillies in many gardens, which ufes its own dung as the matter to form its cafe of. This fpecies at length becomes a beetle. Another fmall beetle of a purple colour, and very remarkable for its beauty, is produced from a fmall worm of this moth kind, which is as remarkable for its uglinefs; this has three pair of cruftaceous feet, as the other worms of the beetle kind have: both thefe kinds, while in the *Tinea* or worm ftate, collect together all their dung as they void it, and, by a very nice fort of workmanfhip, form themfelves very compact and firm cafes of it, which they drag about with them where-ever they go.

Finally there is another field *Tinea*, the beetle produced by which is of a purple colour on the body, and black in every other part. This, while in the worm ftate, covers itfelf with a cafe made of its own dung, but has this fingularity, that when the time of its change approaches, it defcends to the ground, and buries itfelf there till the time that it comes out in form of a beetle.

All thefe animals might have been defcribed as the dependants on the beetle and fly kinds; but as they have this remarkable quality of feeding in the fame manner, and making themfelves cafes of different materials in the manner of the *Tinea* or cloaths moth while in the worm ftate, and in this ftate they are much more obvious to the eye than the flies, beetles, &c. produced of them, many of which are fo fmall as to efcape obfervation; this accurate author has chofen to defcribe them together, and in this their imperfect ftate. He adds an account of another fet of animals fomewhat allied to them, which he therefore calls the *pfeudo-Tinea*, or falfe moth. *Reaumur*, Hift. Inf. Tom. I. See the article PSEUDO-*Tinea*.

TINEMAN, in our old writers, a petty-officer in the foreft, who had the nocturnal care of vert and venifon, and other employments in the foreft. Leg. *Canut.* ap. *Blount*.

TINET, *Tinettum*, in our old writers, is ufed for brufhwood and thorns to make and repair hedges. In Herefordfhire to *tine* a gap in a hedge is to fill it up with thorns, that cattle may not pafs through it. Chart. *Blount*.

TINEWALD, the parliament or annual convention of the people of the Ifle of Man, of which this account is given; the governour and officers of that ifland do ufually fummon the twenty-four keys, being the chief commons thereof, once every year, *viz.* Upon Midfummer-day at St. John's chapel, to the court kept there, called the *Tinewald*-court; where, upon a hill near the faid chapel, the inhabitants of the ifland ftand round about the plain adjoining; and here the laws and ordinances, agreed upon in the chapel of St. John, are publifhed and declared unto them. At this folemnity the lord of the ifland fits in a chair of ftate with a royal canopy over his head, and a fword held before him, attended by the feveral degrees of the people, who fit on each fide of him, &c. *King's* Defcipt. of the Ifle of Man.

TINGING *of Marble*. The art of doing this has in feveral peoples hands been a very lucrative fecret, tho' there is fcarce any thing in it that has not at one time or other been publifhed.

Kircher has the honour of being one of the firft, who publifhed any thing practicable about it. This author meeting with ftones in fome cabinets fuppofed to be natural, but having figures too nice and particular, to be fuppofed of nature's making, and thefe not only on the furface, but funk through the whole body of the ftones, was at the pains of finding out the artift who did the bufinefs; and on his refufing to part with the fecret on any terms, this author with Albert Gunter a Saxon endeavoured to find it out; in which they fucceeded at length very well. The method is this,

Take aqua fortis and aqua regia of each two ounces, fal armoniac one ounce, fpirit of wine two drams, about twenty-fix grains of gold, and two drams of pure filver, let the filver be calcined and put into a vial, and pour upon it the aqua fortis, let this ftand fome time, then evaporate it, and the remainder will firft appear of a blue and afterwards of a black colour. Then put the gold into another vial, pour the aqua regia upon it, and when it is diffolved evaporate it as the former. Then put the fpirit of wine upon the fal armoniac and let it be evaporated in the fame manner. All the remainders and many others made in the fame manner from other metals diffolved in their proper acid menftrua, are to be kept feparate and ufed with a pencil on the marble. Thefe will penetrate without the leaft affiftance of heat, and the figure being traced with a pencil on the marble, the feveral parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the defired depth into the ftone. After this the mafs may be cut into thin plates, and every one of them will have the figure exactly reprefented on both furfaces, the colours never fpreading: The niceft method of applying thefe, or the other *tinging* fubftances, to marble, that is to be wrought into any ornamental works, and where the back is not expofed to view, is to apply the colours behind, and renew them fo often till the figure is fufficiently feen through the furface on the front, though it does not quite extend to it. This is the method that of all others brings the ftone to a nearer refemblance of natural veins of this kind. *Kircher's* Mund. Subter.

TINNITUS *Aurium* (*Cycl.*)—In the *Tinnitus*, the ear ufually receives founds which do not exift, or at leaft which are not produced by the motion of the external air; and the ear be-

ing filled with a certain fpecies of found, cannot admit other founds, unlefs they are very violent.

The antients imagined that this fymptom was produced by the motion and agitation of the air which was included in the ear, and fuppofed this agitation to be occafioned by flatulencies and vapours being conveyed into the ear, and that thofe flatulencies arofe either from the whole body, as in fevers; or from any particular part, as the ftomach, or brain; or from pituitous humours lodged in the cavities of the ear; and from the differences of thefe they attempted to account for all the various noifes heard in this diforder, as if they were in fome fort real: but when we confider the nature of the noifes heard in this diftemperature of the ear, fuch as the loud roaring, or the murmuring of waters, and the jangling of bells, we fhall eafily conceive thefe can be no real founds; and it is indeed very evident that they do not arife from either wind, or any other matter, ftriking the membranes externally.

As a *Tinnitus* confifts in the hearing a found which either is not real or exifts only within the ear, in order to conceive the meaning of this, we are to confider that the action of hearing confifts in the agitation of the immediate organ appointed for that purpofe; and it is fufficient to produce a found that that organ is agitated, whether it be by the air or not. In order to determine what may be the caufe of this agitation, we need only examine what are the diforders in which a *Tinnitus* ufually occurs; we fhall find thefe to be inflammations, and abfceffes of the tympanum and labyrinth, and the diforders of the meatus auditorius. Inflammations of the tympanum and labyrinth neceffarily produce agitations in the fpiral lamina and in the femicircular ducts, either by tenfion of the membrances, or by the vapours which tranfpire, and mix themfelves with the air in the tympanum.

Acrid fubftances, worms, extraneous bodies, a conftriction of the meatus fucceeding a diftenfion of the glands, and in general every thing that can caufe in the meatus auditorius, pain, and the other fymptoms before defcribed, agitate the membrane of the meatus, and the membrana tympani; and this agitation is able to communicate itfelf to the immediate organ of hearing.

The fecond fpecies of *Tinnitus* is when we perceive a real found which is formed within the ear itfelf: thus we hear a humming noife when we ftop our ears. This noife is caufed by the friction of the hand, or by the compreffion which influences the fkin and cartilages, whofe parts being put into motion may produce an agitation there. The elafticity of the air alfo and the tranfpired matter from the hand, mixing with the internal air in the meatus, may alfo ftrike the organ, tho' not ftrongly, yet fufficiently to occafion a noife, as the offending matter is fo near.

Commotions of the cranium, and diforders which contract the meatus, may alfo caufe a *Tinnitus* in the ear. Several perfons alfo are fubject to a peculiar noife in the ear, which is plainly a pulfation; this ufually affects them moft after exercife, and may very often be heard by other perfons, who place their heads near the difeafed perfon's ear: this is unqueftionably the true pulfation of a dilated artery, fince it always regularly keeps time with the heart.

There feem alfo to be fome fpecies of *Tinnitus*, in which, tho' the humming noife is very ftrong, yet the organ of hearing is itfelf no way diftempered; fuch are thofe of perfons in deliriums in fevers, and of fuch as are fubject to epileptic fits; thefe laft ufually hear a humming in their ears, before they are attacked with a fit, and this feems wholly produced by the agitated fpirits, which difturb thofe parts of the brain where the extremities of the auditory nerve terminate.

The *Tinitus* are therefore of two kinds; the one proceeding from a diftemperature of the organ of hearing, the other from a diforder of the brain; and the cure is to be attempted accordingly. In the fharper *Tinnituffes*, which are ufually occafioned by inflammations and pains in the ear, where the parts are ufually very tenfe and dry, we muft ufe the fame means as in acute pains, and tenfions of the membrana tympani; but in dull humming heavy noifes, which are ufually occafioned by rheums and fuppurations, where the membranes are relaxed, we are to ufe the fame remedies which give relief in pains occafioned by cold: After which it will be no difficulty to chufe the moft proper, while we have a due regard to the circumftances, from which the more juft indications may be taken. *Du Verney*.

TINNUNCULUS, in zoology, the name of one of the long-winged hawks, called by others *Cenchris*, and in Englifh, *Keftrel*, *Stannel*, or *Windhover*.

It is about the fize of a common pigeon. Its bill is fhort, crooked, and very fharp, and covered with a yellow fkin at the top; near this the bill is white, elfewhere it is blue. Its tongue is bifid; its mouth very wide, and its palate blue. Its head is large and flatted, and is of an afh-colour, with longitudinal ftreaks of black. Its back and wings are brown, variegated with black fpots; its rump is grey, with fome tranfverfe black fpots; and its breaft and belly of a pale ruft-colour, with a few longitudinal ftreaks of black. Its tail is long and pointed, its tip of a pale ferrugineous hue, with a broad tranfverfe ftreak of black over it; and the reft of the tail is a mixed grey and brown, with black fpots and ftreaks. Its legs and feet are of a fine yellow. It builds in hollow oaks, and lays four eggs, which are white, variegated with a number of fmall red fpots. It feeds on partridges and other birds. *Ray*, Ornithol. p. 50.

TINTINNABULUM, among the antients. See the article BELL.

TINUS, *Lauruftine*, in botany, the name of a genus of trees, the characters of which are thefe: The flower confifts of only one leaf, and is of the rotated kind, and divided into many fegments at the edges. The center of the flower is perforated by the pointal of the cup, which finally becomes an umbilicated fruit, of the fhape of an olive, containing a pear-fafhioned feed.

The fpecies of *Tinus*, enumerated by Mr. Tournefort, are thefe: 1. The common *Lauruftine*. 2. The *Lauruftine* with nervous leaves. And 3. The fmall-leaved *Lauruftine*. *Tourn*. Inft. p. 607.

TIPHLE, in zoology, a name by which fome authors exprefs the acus, or tobacco-pipe fifh. *Bellon*. de Aquat. 446.

TIPIOCA, a name given by fome authors to a fort of cream or flower made from the yucca or manihot-root, by maceration of it in water, after expreffing the juice.

TIPSARIA, or TAPSARIA, a word ufed by fome medical writers for barley-water.

TIPUL, in natural hiftory, a name given by the people of the Philippine iflands, to a fpecies of crane common there, and fo tall, that when it ftands erect, it can look over a man's head.

TIPULA, in natural hiftory, the name of a genus of fly, remarkable for the great length of its legs, and ufually called by us the *long-legs*.

There are a great variety of kinds of the *Tipulæ*; and the fmaller fpecies fo much refemble gnats, that the generality of authors, not excepting even Goedart and Swammerdam, have confounded the two genera, and defcribed thefe among the gnats. The external appearance, however, is all that conveys an idea of likenefs between them; for the gnat is furnifhed with a trunk, and other offenfive weapons, by means of which it is able to pierce our flefh; and, on the other hand, the *Tipula* has only a mouth without teeth, and has neither inclination, nor is in a condition to do any harm. It is indeed very happy for us, that this is the cafe, fince the *Tipulæ* are greatly more numerous than the gnats, and were thofe vaft clouds of fmall *Tipulæ*, which we fee in marfhy places and elfewhere, and ufually call clouds of gnats, in reality fuch numbers of thofe mifchievous animals, we fhould not eafily efcape a good deal of trouble from them.

The long form of the body, the pofition of the wings, and the length and pofition of the legs, are the circumftances that make the refemblance between the gnats and *Tipulæ*; but the ftructure and organs of the head are alone a very fufficient diftinction. All the fpecies of gnats have their origin from water-infects, whofe form they never quit, till they become winged; but the *Tipulæ* are not fo regular, in this refpect; fome of them being produced from water-worms, and others from infects of the like form, that have lived on earth, and preyed upon the juices of plants.

As the *Tipulæ* differ from the gnats in the figure of the mouth, and in being without a trunk, they differ as much from the other flies of that character, by their refembling the gnat in the fhape of their body. They differ alfo in the conformation of the mouth, and its feveral parts and organs. The opening of the mouth is a flit extending itfelf from the fore-part of the head toward the hinder part, and its lips cannot be called upper and lower; but they are lateral ones. When the body of the creature is preffed, this mouth opens, and fhews what feem to be a fecond pair of lips within. Thefe are more firmly clofed than the others, and refemble only certain duplications of the flefh. The exterior lips are cartilaginous, and are furnifhed with fhort hairs; the interior are perfectly fmooth, and of a flefhy texture. The head of the *Tipula* is of a long and flender figure, and is of the nature of thofe which we call the femi-trunk heads, as they much approach to the figure of the trunks of fome other infects. The lips are articulated at the extremity of this head, and on each fide there ftands, on the upper part, a fort of beard, which, when nearly examined, is found to be articulated in the manner of the antennæ of infects. Thefe two beards, in their ufual pofition, are placed clofe together, and bent forwards over the head: Their office feems to be the covering the aperture of the mouth. Thefe feem conftantly to be found in all fpecies of the *Tipulæ*, and placed exactly in the fame manner. They may therefore be ufed as a character of the creature; and if there fhould be found any fpecies wholly refembling the *Tipulæ*, but wanting thefe, it may be very properly called a *protipula*. *Reaumur*, Hift. Inf. vol. 9. p. 7.

The larger fpecies of *Tipulæ* are ufually found in our meadows, and thefe are in no danger of being confounded with the gnat kind, their fize alone being a fufficient obvious diftinction. Thefe are often found of nearly an inch in length from head to tail; but their bodies are very flender, and are compofed of only nine rings. The male *Tipula* is eafily diftinguifhed, at fight, from the female. It is much fhorter in the body, and is thicker at the tail than any where elfe; this tail alfo ufually turns upwards, whereas that of the female is placed in the

fame

ſame line with the body, and is ſlender, and compoſed of ſeveral ſcaly parts, proceeding from the laſt ring of the body. Theſe creatures are found in our meadows through the whole ſummer; but the end of September and beginning of October is the time when they are moſt of all plentiful: They are ſo common in ſome meadows, in theſe months, that there is no walking a ſtep without putting up whole flights of them. They are extremely well furniſhed by nature either for walking or flying. In the middle of a hot day they will often riſe to a great height in the air, and take long flights; but at other times they uſually only fly to one part of a field from another. They ſometimes uſe their wings alſo in the manner of the oſtrich, aſſiſting their legs with them in running; and ſometimes they make no ſmall uſe of their legs in their ſhort flights, the ſpring with which they throw themſelves off from a plant, carrying them to half the diſtance they are going to.

The legs of theſe creatures are greatly diſproportioned to the body, according to the common rules of nature, eſpecially the hinder pair, which are in the larger ſpecies uſually three times the length of the body. Theſe carry them ſafely and eaſily among the plants, and ſeem of the ſame uſe to them that ſtilts are to boys, in wading through dirt. This large ſpecies is a creature of no great beauty. Its body is of a browniſh colour, and its corcelet is ſo elevated, that the creature ſeems hump-backed. The head is ſmall, and the neck very ſhort. The reticulated eyes are ſo large, that they cover almoſt the whole ſurface of the head; theſe are of a greeniſh colour, with a caſt of purple, when viewed in ſome lights. Mr. Reaumur very carefully examined the head, to find out ſome of thoſe ſmaller ſhining eyes which other inſects of the fly kind have, and which reſemble thoſe of ſpiders: Theſe are uſually placed in a triangular figure on the head; but in this creature there are none of them in the common place; there appear indeed two lucid ſpecks, one at the origin of each of the antennæ, when the head is carefully examined with a microſcope: But Reaumur does not allow theſe to be eyes, he rather ſuppoſes that two very lucid ſpecks, on the anterior part of the breaſt, are eyes, though placed in ſo very ſingular a manner. The wings of this creature are long, but very narrow, and ſeem ſcarce well proportioned to the ſize of the animal; they are tranſparent, but have a ſlight caſt of brown; and their ribs, when viewed by the microſcope, appear beſet with ſcales, or feathers, in the manner of thoſe of the gnat kind. Some ſpecies of the *Tipulæ* have them alſo fringed, with theſe ſcales at the edges. There are no ailerons, or petty-wings, at the origin of theſe, as is the caſe in many of the other ſpecies of two-winged flies; but in the place of them there are two very fine balancers or mallets. Theſe have long pedicles, and roundiſh or oval heads. The ſtigmata of the corcelet are four; one pair are placed immediately underneath theſe balancers, and the other immediately below the firſt pair of legs. The firſt pair are very long, the others ſmall, and thoſe on the rings of the body, if there be any, are too ſmall for our ſight, even with good glaſſes. Each ring of the body is compoſed of two half cylinders, which are joined into one, by means of a membrane, which gives them room to diſtend or cloſe up at the creature's pleaſure. The large *Tipulæ* all carry two antennæ, or horns, upon their head; but theſe are of no remarkable ſtructure, they are only compoſed of a great number of joints, each covered with a fine downy hairyneſs; and at the joining of each to the next, there is a tuft of longer and more ſtiff hairs. This is the deſcription of the common large *Tipula* which we find in the meadows; and in almoſt all its parts, is applicable to the generality of the larger ſpecies of theſe inſects. *Reaumur*, Hiſt. Inſ. vol. 9. p. 13.

The ſmaller kinds are very numerous, and of great variety. Theſe are frequent in all places, and at all ſeaſons of the year: The ſpring ſhews us immenſe clouds of them, and even the coldeſt winter's day ſhews a great number of them in the ſunſhine about noon. Theſe creatures fly much better than the large *Tipulæ*; they ſeem indeed to be almoſt continually upon the wing, and their manner of flight is very ſingular; they are continually mounting and deſcending again, and that without quitting the direction of the line they go forward in; this they will often do for many hours together. In tracing theſe flies from their origin, they are all found to be produced from worms which have no legs, and have a regular ſcaly head. Thoſe from which the larger *Tipulæ* are produced, live under ground; they are moſt fond of marſhy places; but any ground will do that is not often diſturbed. They uſually are found at about an inch under the ſurface, and are ſo plentiful in ſome places, as greatly to injure the herbage. When they get into corn-fields, they cauſe whole acres of the corn to wither before it grows into the ear, and even in paſture-land the graſs is ſometimes ſo entirely deſtroyed by them, that there is no food for cattle in places where the herbage uſed to be ever ſo plentiful and ſtrong. It has been ſuppoſed from this, that they eat up the roots of the plants; but this is not the caſe; they feed only on the ſmall inſects which live under ground, and take in a large quantity of dirt with them into their ſtomachs. The miſchief they do, is by their being continually in motion, and looſening by this means the earth from about the roots, ſo that they dry up with the ſucceeding heat of the ſun.

Theſe creatures do not find it neceſſary to their living, that plants ſhould be upon the ſurface of the earth in which they live. There is frequently found in the hollows of the ſtumps of old trees, a ſort of earth which ſeldom produces any vegetables; yet the female flies of this ſpecies well know that their young will find a proper ſubſtance there; and there are uſually found great numbers of them in all theſe places. The hollow elms and willows, ſo common in our hedges, and by ditch-ſides, afford innumerable proofs of this: but it muſt be obſerved, that they are only found in ſuch earth of this kind, as is continually ſomewhat moiſt; that is, ſuch as is placed in a cavity which will retain the wet that falls into it; for when the earth lies in places where the water eaſily drains off, there never are found any of theſe inſects in it. Mr. Reaumur mentions a very ſingular ſpecies of large *Tipula*, which was produced with him from one of the worms found in the earth of an old elm; this was of the larger kind, and had ſome beautiful ſpots on the wings. It had alſo very elegant tuſted antennæ; whereas, in the common large *Tipulæ*, theſe are plain and ſimply granulated ones, as well in the males as females. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 17.

Mr. Ray, in his hiſtory of inſects, deſcribes fourteen ſpecies of this fly found in England. 1. The common *Long-legs*. This is about an inch long, and its antennæ are ſhort and ſlender, and its eyes black. The male of this ſpecies is more obtuſe at the tail than the female. 2. A very large kind, with large wings ſpotted with brown and white. 3. A large kind, with two large black ſpots on the wings. 4. A very beautiful *Tipula*, with black ſhoulders and back, a yellow belly, and ſome brown ſpots on the wings. 5. The yellow-winged *Tipula*, with ſpots on the wings, and a black and yellow body. 6. The common ſmall *Tipula*, with brown wings, ſpotted with white, and with opake dark brown ribs. 7. The middle-ſized black and yellow *Tipula*. 8. The long-legged *Tipula*, with ſhining black eyes. 9. The ſmall purple-winged *Tipula*, with a black back and yellow belly. 10. The middle-ſized green-eyed *Tipula*. 11. The browniſh-grey *Tipula*, with extremely long antennæ. 12. The elegant *Tipula*, with plumoſe antennæ. 13. The ſmall *Tipula*, with brown wings ſtreaked with black. And 14. The ſmall *Tipula*, with ſtriated wings, each having one very large black ſpot near the end. *Ray*'s Hiſt. Inſ. p. 72.

The white *Tipula* is a very beautiful little inſect; it is very common in gardens, and among buſhes in September and October; and tho' it appears all over white when ſeen at a diſtance, yet is not found to be ſo when examined more nearly. The wings, when the creature is ſitting, cover the whole body, and theſe are white; but the body itſelf is of a yellowiſh-green in that part next the head, and of a browniſh-black in the hinder part. The head of this creature is very ſmall, but the antennæ, or horns, are extremely long, and very beautifully feathered; they ſeem indeed a load to the creature to carry, and in their uſual poſition are croſſed one over the other in ſuch a manner, as to appear only one body together. *Reaumur*, Hiſt. Inſ. vol. 9. p. 20.

TIRATA, in the Italian muſic, is uſed to expreſs, in general, any quantity of notes, of whatever kind, provided they be of equal value, moving either upwards or downwards in conjoint degrees; thus they ſay, *Tirata di Semiminime*, when there are many crochets following one another in the manner above mentionod; *Tirata di Legâture*, when there are many notes of the ſame value following one another, among which the laſt of one bar, and the firſt of the next, are tied together by a ſemicircle, thus; ◡ or ⌒.

Tirata is particularly uſed for a ſeries of quavers, or, in the modern notation, of demi quavers or demi-ſemi-quavers, aſcending or deſcending by gradual intervals.

Theſe *Tirate* often, tho' not neceſſarily, begin with an unaccented note, and end on ſome accented one of greater duration. See the example annexed.

Muſicians diſtinguiſh ſeveral kinds of *Tirate*, thus:

1. *Tirata mezza*, or *mezza Tirata*, is that compoſed of three or four quick notes to aſcend, or deſcend to a note, a fourth, or fifth, higher or lower than the note from whence the *Tirata* begins; as in the examples before given.

2. *Tirata defectiva* is when theſe running notes go beyond the fifth, but do not reach the octave.

3. *Tirata perfecta*, is when it runs through the notes of a whole octave, aſcending or deſcending.

4. *Tirata aucta*, or *excedens* is when it goes beyond the compaſs of an octave.

The French call the *Tirata*, *Tirade*, and ſome call them *roulodes*, but improperly, ſays Broſſard.

TIRSIO, in ichthyology, a name given by Gaza and ſome other authors to the phocæna of Willughby and others, the porpeſſe, or marſuin. It is a ſpecies of the delphinus, according to the Artedian ſyſtem; and is called the dolphin with a conic ſhaped body, a broad back, and a ſharp ſnout. Pliny,

Bellonius, and many others, call it *turfio*. See the articles TURSIO, PHOCÆNA, and DELPHINUS.

TIRSITES, a word ufed by fome to exprefs foffile coral.

TISRI, or TIZRI, the firft hebrew month of the civil year, and the feventh of the ecclefiaftical or facred year.

The Hebrews call it *Rofh-hafhanna*, that is, the beginning of the year. It anfwered to the moon of September. On the firft day of this month was kept the feaft of trumpets, becaufe the beginning of the year was then proclaimed by found of trumpets. On this day they refrained from all forts of fervile bufinefs, and offered in facrifice a calf, a ram, and feven Lambs. Levit. xxiii. 24. Numb. xxix. 1. *Calm.* Dict. Bibl. in voc.

TITANIA, τιτανια, in antiquity, a feftival in memory of Titanes. *Potter*, T. 1. p. 433.

TITANOS, a word ufed by fome authors to exprefs lime, by others for the calx of burnt gypfum or plaifter of Paris, and by others a lixivium of quicklime.

TITHENIDIA, τιθηνιδια, in antiquity, a Spartan feftival, fo called from τιθηναι, nurfes, who at this time carried the male infants committed to their charge to the temple of Diana Corythallia. For the ceremonies obferved on this occafion, fee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 432. feq.

TITHYMALOIDES, in botany, the name of a genus of plants, the characters of which are thefe: The flower is compofed of only one leaf, and in fome degree refembles a fhoe; the piftil finally becomes a fruit like that of the *Tithymal* or fpurge.

The fpecies of *Tithymaloides* enumerated by Mr. Tournefort are thefe: 1. The fhrubby *Tithymaloides* with very large myrtle-like leaves. 2. The orpine-leaved fhrubby *Tithymaloides*. 3. The nerium-leaved fhrubby *Tithymaloides*. *Tourn.* Inft. p. 654.

TITHYMALUS, *Spurge*, in botany, the name of a large genus of plants the characters of which are thefe: The flower confifts of one leaf, and is of the campaniform kind but globofe, divided into feveral fegments at the edge, and inclofed in two little leaves which feem to ferve in the place of a cup to it. The piftil arifes from the bottom of the flower, and is ufually of a three-cornered fhape; this ripens into a fruit of the fame form, which contains many oblong feeds.

The fpecies of *Tithymal* defcribed by authors are thefe: 1. The myrtle-leaved tree-*Spurge*. 2. The broader-leaved tree-*Spurge*; this is evidently no other however than a variety of the firft fpecies, fince, though very different in appearance, it arifes from the feeds of that plant. 3. The turberofe-rooted tree-*Spurge*, with fmooth leaves, and a rough wart-like feed. 4. The leaflefs African tree-*Spurge*. 5. The cotinus-leaved American tree-*Spurge*. 6. The cotinus-leaved tree-*Spurge*, with fmaller leaves ftanding in bundles about the ftalk. 7. The blunt almond-leaved tree-*Spurge* of America. 8. The toad-flax-leaved tree-*Spurge* of America. 9. The box-leaved fhrubby American-*Spurge*. 10. The pale flowered Æthiopian tree-*Spurge*, with leaves like thofe of the German mezereon. 11. The red almond-leaved exotic-*Spurge*. 12. The wood-*Spurge*, with lunated flowers. 13. The hairy-leaved almond-*Spurge*. 14. The creeping-rooted almond-*Spurge*. 15. The gromwel-leaved *Spurge*. 16. The broad-leaved *Spurge*, called *lathyris* and *cataputia* by authors. 17. The broad leaved Spanifh *Spurge*. 18. The wild German broad-leaved *Spurge*. 19. The yellow-leaved *Spurge*, with hairy and finely indented leaves. 20. The foft hairy wood-*Spurge*. 21. The great broad-leaved *Spurge*. 22. The hoary meadow-*Spurge*. 23. The red-ftalked willow-leaved and blite-leaved *Spurge* of Curaffo. 24. The green ftalked willow and blite-leaved *Spurge* of Curaffo, with fmooth leaves. 25. The little annual narrow-leaved *Spurge*, called by many authors *efula*. 26. The little rock-*Spurge*. 27. The obtufe-leaved little *Spurge*. 28. The annual *Spurge* with leaves like thofe of flax. 29. The gentle mountain fmall *Spurge*, called fweet *Spurge*, and *efula dulcis*. 30. The wart-*Spurge*, or rough-fruited *Spurge*. 31. The narrow-leaved wart-*Spurge*. 32. The narrow-leaved almond-*Spurge*, called *alypum* by fome authors. 33. The cyprefs-*Spurge*, called alfo *humipinus*, and *efula* in the fhops. 34. The red-bearded cyprefs-*Spurge*. 35. Alpinus's cyprefs-*Spurge*. 36. The toad-flax-leaved *Spurge*, with a lunated flower. 37. The pine-leaved *Spurge*, the *pithiufa* of Diofcorides. 38. The fea-*Spurge*, called *Tithymalus paralius*. 39. The flax-leaved tree-*Spurge*, called by Boccone the juniper-leaved fea-*Spurge*. 40. The prickly fea-*Spurge*. 41. The narrow-leaved almond-*Spurge*. 42. The jaggy-leaved almond-*Spurge*. 43. The almond-*Spurge*, with a thick pear-fafhioned root. 44. The little willow-leaved *Spurge*. 45. The tuberofe or knotty-rooted *Spurge*, called by fome *apios*. 46. The long-rooted tuberous *Spurge*. 47. The fhrubby marfh-*Spurge*. 48. The broad-leaved triangular-fruited Portugal *Spurge*. 49. The olive-leaved bluifh green *Spurge*. 50. The little fmooth *Spurge*, with leaves like thofe of money-wort, called *chamæfyche*. 51. The little hairy *Spurge*, with leaves like thofe of money-wort. 52. The roundifh-leaved not dentated *Spurge*, called by authors *peplus*, and *efula rotunda*. 53. The common fun-*Spurge*, or heliofcope-*Spurge*. 54. The annual *Spurge*, with oblong fharp pointed leaves, called by Boccone the annual *peplis* with a moffy flower. 55. The creeping annual *Spurge*, with a rounded yet pointed leaf. 56. The red fea-*Spurge*, with obtufe and auriculated leaves; the leaves and ftalk of this plant are all red. 57. The green fea-*Spurge*, with obtufe auriculated leaves; both the leaves and ftalk of this are green. 58. The many-fruited Sicilian *Spurge*, with leaves like thofe of purfelain. 59. The perennial fhort blunt-leaved kind. 60. The Spanifh kind, with long heart-fafhioned leaves. 61. The Aleppo *Spurge*, with round hoary leaves. 62. The fpreading American *Spurge*, with ferrated leaves, and flowers ftanding in clufters in the alæ of the leaves. And, 63. The erect American *Spurge*, with ferrated leaves, and cluftered flowers ftanding on long foot-ftalks. *Tournef.* Inft. p. 88.

TITILLARES *Venæ*, a name given by fome Authors to the iliac veins.

TITILLICUM, a word ufed by fome anatomical writers for the arm-pit.

TITMOUSE, in zoology. See the articles PARUS, and FRINGILLAGO.

TITT, in the manege. See the article NAG.

TIZRI, a Jewifh month, anfwering to our September moon. See the article TISRI.

TIZZONAIOS, in the glafs art, are two apertures, one on each fide the working furnace, by which a fervitor night and day puts in coals to maintain the fire. *Neri*'s art of Glafs, p. 242.

TLAM, or SLAM, in the alum works, a word ufed by the workmen to exprefs a fort of mud or foulnefs which does great hurt to the alum, rendering it foul and coarfe. The *flam* is a muddy fubftance fettling to the bottom of the veffels; but in the boiling the liquor it gives it a reddifh colour, and diforders the whole works when in any great quantity. They always pafs their liquor over four parcels of the alum rock, and the laft if not carefully calcined generally gives it this difadvantageous mixture. Phil. Tranf. N°. 142.

TLAOLI, in botany, a name ufed by fome authors for the plant called *maize*, *frumentum Indicum*, or Indian wheat. *Hernand.* p. 242. Pifo, Mant. Arom. p. 99.

TLAPALEZ-PATLI, in botany, a name ufed by fome authors for the tree whofe fruit is the ben-nut, and whofe wood the Lignum Nephriticum of the fhops. *Hernand.* p. 119.

TLAQUACUM, in zoology, the name given by the Spaniards and fome others to a very remarkable animal in America, commonly known among us by the name of the *poffum* or *opoffum*. See the article OPOSSUM.

TLAQUATZIN, in zoology, a name by which the natives in fome parts of America call the *opoffum*. See the article OPOSSUM.

TLAQUATZIN *Spinofum*, in zoology, the name by which Hernandez has called the cuanda, a fort of Brafilian porcupine. See the article CUANDA.

TLATLANCUAYE, in botany, a name by which fome authors have called the plant which produces the long pepper ufed in medicine. *Hernandez*, p. 126.

TLANHQUACHUL, in zoology, the name of a Brafilian bird, very much approaching to the nature of the European platea or fpoonbill.

It is a very voracious bird, and feeds on live fifh, but will not take or meddle with dead ones, and is all over of a beautiful red. It has a black ring round the upper part of its neck, and is common about the fhores of the fea and rivers. *Marggrave*'s Hift. of Brafil. See the article PLATEA.

TLAYOTIC, in natural hiftory, the name of a ftone found in new Spain, and ufed as a fovereign remedy againft the colic, and feveral other difeafes: it is a fpecies of jafper, approaching to the nature of the lapis nephriticus, and of a green colour. The natives cut it into feveral forms for ufe. See the article *Colicus* LAPIS.

TLEUQUECHOLTOTOTL, in zoology, the Mexican name of a bird of the wood-pecker kind, defcribed by Nieremberg, under the name of the *avis falutiferus*; the feathers of a red creft it carries on its head, being fuppofed a remedy for headachs.

TLILZOCHITL, in botany, a name ufed by fome authors for the plant whofe pod is the fruit called vanilloes, and ufed in chocolate. *De Laet.* Ind. p. 230.

TMOLITES, the name of an excellent wine among the antients, like the Falernian.

TOAD, in zoology. See the article RUBETA.

TOAD-*Fifh*, in ichthyology, an Englifh name for the rana pifcatrix or lophius. See the article RANA.

TOAD-*Flax*. See the article LINARIA.

TOAD-*Powder*, *Pulvis Bufonum*. Dr. Kramer fays, *pulvis bufonum*, when applied by way of pultice, with barley flour and urine, is an excellent remedy for ripening peftilential buboes, but that it has no fuch effect in venereal, or any other than peftilential buboes.

TOBACCO (*Cycl.*)—In the ifland of Ceylon, there are two kinds of *Tobacco* cultivated for profit. They call both kinds *dunkol*, which fignifies a leaf the ufe of which is to be fmoaked. The one kind they call *hingele dunkol*, or *fingele dunkol*; for they make no difference between the letters S and H in their pronunciation; the other they call *dunkol kappada*; *kappada* fignifies gelding, and is a word of Portuguefe origin. This *kappada-Tobacco* is much ftronger and more intoxicating than the other; but both kinds are the produce of the fame plant; only the fingle *Tobacco* has very little care

 taken

taken of it, being, after the sowing, in a manner left to itself, while the other has great pains bestowed upon it during the whole time of its growth, and till it is fit for use, in the following manner: They clear a little piece of ground, in which they sow the seed of the *Tobacco*, and against the time that the young plants have got three leaves a-piece, they choose out another piece of ground into which to transplant them: This they hedge round, and turn their horned cattle into it, that their dung may fall upon it, and sufficiently enrich it. The ground is then dug with a sharp hoe, or spade, in the form of a pick-ax, and the dung, by this means, thoroughly worked into it. When the earth is thus prepared, they take up the young plants, and set them in this new ground, at about a foot square distant from one another.

The manner of giving more or less strength to this *Tobacco*, is by suffering the plants to grow to a greater or less height before they top them, or cut off the stalk at the summit. The usual way is to cut off the top when the plant has fifteen leaves. If they intend the *Tobacco* to be a little stronger, they do this when it has only thirteen; and when they would have it strongest of all, they do it when there are only eleven or twelve leaves. On the contrary, when they would have a milder *Tobacco*, they cut it not off till there be eighteen or twenty leaves; but in this way of counting the leaves, they never reckon the three or four lowest, which do not grow so large and fine as the others. The cutting off the top, prevents the juices of the plant from being wasted in flowers and seeds, which are of no value; and, in consequence of it, all being, after this time, employed to furnish the growth of the leaves, they grow four times as large and thick as they otherwise would do.

To prevent all unnecessary wasting of the sap, these plants are tended every day; and as the young sprouts appear in the joining of the leaves and stalk, they are continually cut off: This is done once in three days, till the leaves have their full bigness, which is about that time when the flowers would have been ripe, had the plant been suffered to grow in its natural way: They are immediately to be gathered when they are full grown, otherwise they waste and decay. They cut down the whole plant, and bring them into their houses, laying them on a heap. When they have lain a little time together, they begin to sweat and grow hot: When they have been a little while fermenting, they turn them, bringing those which were in the middle to the surface, and placing those which were at the surface in the middle; by this means the whole quantity of leaves ferments equally. The longer they lie in this manner, the darker-coloured the *Tobacco* becomes. When they have left it thus to sweat as long as they judge necessary, they hang every stalk separately on cords; and when the whole is thoroughly dry, they carefully take off the leaves, and lay them by in bundles, till they have occasion for them. This is the manner of their preparing the *kappada*.

The single *Tobacco* is sown in the same manner with this; but it is never transplanted nor tended, it grows as it pleases, and when the flowers are ripe, it is cut down, and laid carelessly in heaps, where some of it ferments too much, and some too little. This is much weaker therefore than the *kappada*; and as both kinds are common in the place, the natives smoak them either separately or together, mixed in different proportions, as they like. Some of the Ceilonese chew this strong *Tobacco* with their beetle, and some, who smoke it alone, use no pipe, but, taking a long leaf of it, they roll it up into a long form, and cover it with the leaf of the wattukan-tree; they then light one end of it, and smoak by the other, till the whole is consumed. Philos. Transf. N°. 278. p. 1145.

There are four or five kinds of *Tobacco* frequently raised by the curious in England. They are to be sown in March, upon a moderate hot-bed, and when the plants are come up, they should be transplanted to another hot-bed of moderate warmth, and set at four inches distance, watering and shading them till they have taken root: And as they grow stronger, giving them as much air as the season will permit. In the beginning of May the plants will grow so large as to touch one another; and they are then to be taken up with a large ball of earth about their roots, and removed to a good soil, where they are to be planted at two foot asunder every way. *Miller*'s Gardener's Dict.

Tobacco beat into a mash with vinegar or brandy, and laid on the stomach, has sometimes good effects in removing hard tumours of the hypochondria. We have the history of two cures made by such applications in the Medic. Ess. Edinb.

The juice of this plant is said to be good against ulcers and mortifications. *Boyle*, Works abr. Vol. I. p. 56.

TOBACCO-*Pipe Fish*, the English name of the *acus*. See Tab. of Fishes, N°. 25. and the article ACUS.

TOBACTLI, in zoology, a name which Nieremberg says is often given to the American bird, more commonly called *Hoactli*. See the article HOACTLI.

TOBIANUS, in ichthyology, a name given by Schoneveldt and others, to the ammodytes, or sand-eel.

TOBIS, in ichthyology, a name given by the Swedes to the ammodytes, or sand-eel. The name *Tobianus*, given to this fish by Salvian, seems formed from its Swedish name *Tobis*. Salvian is the first author who has described this fish, but his figure is not accurate, for he has given it two back fins instead of one.

TOCCATA, in the Italian music, is much the same as *Ricercata* or *Phantasia*, *Tastatura*, &c. But what distinguishes the *Toccata* from the other kinds of symphonies, is, first, its being usually played on instruments that have keys, as organs, spinnets, &c. Secondly, that it is commonly composed to exercise both hands. Thus, sometimes the bass holds out a sound, while the upper part makes diminutions, passages, or tiratas; and afterwards this part does the same, while the bass moves in its turn. *Brossard*.

TOCCATINA, in the Italian music, a short research, or *ricercata*. See the articles TOCCATA, *Suppl.* and RESEARCH, *Cycl.*

TOCCAVIENSIS *Bolus*, *Bole of Tokay*, in the materia medica, a fine medicinal earth, dug about Tokay in Transylvania, and esteemed a powerful astringent. Kentman calls it the *bolus Pannonica vera*; and Crato, *bolus Hungarica*.

This last author esteemed it superior even to the bole armenic of Galen, and had a great opinion of it in malignant fevers. It is a fine and pure earth, and very heavy, moderately compact in its texture, but not very hard; and in colour of a considerably deep and strong yellow. It is naturally of a smooth surface, and does not stain the fingers in handling. It ferments violently with acid menstrua, and does not become red in burning. *Hill*'s Hist. of Foss. p. 7.

TOCKAY, in zoology, the name of a species of Indian lizard, distinguished from the other kinds, by being spotted all over.

TOCMOL, in natural history, a name given by some to the common turtle.

TODDA-*Panna*, in botany, the name by which many authors call the *palma farinifera*, or sago-tree. *Herm.* Cat. vol. 3. p. 9.

TODTENVOGEL, in zoology, a name by which Gesner and some other authors have called that species of œnanthe, known in England by the name of the *stone-chatter*, *stone-smich*, or *moor-titling*. *Gesner*, de Avib. See the article STONE-*Chatter*.

TOES (*Cycl.*)—*Adhesions of the* TOES. It is a frequent thing to meet with new-born infants with their fingers or *Toes* cohering or grown together, either by a strict adhesion of the flesh, or else by some loose productions of the skin, as in the feet of ducks and geese; and a disorder of the same kind is also sometimes found in adults, from accidents; as when the fingers or *Toes* have been neglected, after an excoriation of them by burns or wounds. In both these cases the surgeon's assistance is necessary, partly to remove the deformity, and partly to restore the proper use of the fingers.

These adhesions, according to the nature of the disorder, are to be separated two ways, either by cutting out the intermediate skin with a pair of scissars, or else barely by dividing them from each other with the same instruments. When this is done, to prevent their cohesions again, each finger must be invested separately with a spiral bandage about an inch broad, dipped in lime-water and spirit of wine.

Sometimes the fingers, instead of adhering to each other, grow to the palm of the hand, from wounds or burns, so that they cannot be by any means extended, or drawn back to open the hand. The method of relieving this disorder is first very carefully to separate the fingers from their adhesions to the palm, without injuring their tendons, then dress them with a vulnerary balsam, and scraped lint, and extend them on a ferula or thick pasteboard; and let them remain in this extended posture, separately to be dressed till they are perfectly healed; but at every dressing they must be gently moved, to prevent a rigidity or stiffness of the joints. *Heister*'s Surgery. p. 330.

Bones of the TOES. Each of the *Toes*, except the greater one, consists of three phalanges. The great *Toe* indeed has but two; but then there are five metatarsal bones, whereas there are but four metacarpal. The bases of the phalanges remain for a long time epiphyses. The first phalanx of the great *Toe* is very like the second of the thumb; but its basis is more hollow, answerably to the convexity of the first bone of the metatarsus, by which it is supported; its head is in form of a pulley, as in the thumb, but much broader: The second, or last phalanx of the great *Toe*, is like the third of the thumb, but bigger and broader, especially at its basis. The tuberosity, in form of a horse-shoe, which terminates this bone, is also more unequal and more flat than in the thumb.

The first phalanges of the other *Toes* are the longest, but they are shorter and more convex than those of the fingers. Their bodies are very narrow, and contracted in the middle, the bases are generally excavated, and the heads made after the same manner as in the fingers. The second phalanges are very short, and almost without shape; both their bases and heads are formed for articulations by ginglymi, but they are very imperfect. The bodies are of some length in the second and third *Toes*; but they are very short in the other two, especially in the little *Toe*, in which the body is broader than it is long. The third phalanges are nearly of the same figure with those of the fingers, but much shorter and thicker in proportion. In the two last *Toes* they are often united with the

the ſecond phalanges, which is owing, perhaps, to the continual inaction and compreſſion occaſioned by ſhoes. *Winſlow's* Anat. p. 103.

Ligaments of the TOES. The firſt phalanges of the *Toes* are tied to the heads of the metatarſal bones, by a ſort of orbicular ligament, ſet round the edges of the cartilaginous portions of the head, and thoſe of the baſes of the phalanges. In the four leſſer *Toes* of each foot, the inferior part of this ligament is very thick, and is cruſted over as it were with a cartilaginous ſubſtance, fixed to the baſes of the phalanges, and from thence continued over the head of the metatarſal bone next it. This ſubſtance grows hard with age like a ſeſamoide bone.

Of theſe ſeſamoide bones, as they are called, the great *Toe* has two belonging to the firſt phalanx, which are largeſt, ſooneſt formed, and moſt conſiderable of all. The ſecond and third phalanges of all the *Toes* being articulated by ginglymi, have lateral ligaments which go between the ſides of the baſes, and thence to the ſides of the heads: At the inferior edges of all theſe baſes there is a cartilaginous matter joined to theſe ligaments, which hardens with age in the ſame manner with thoſe of the firſt phalanges. *Winſlow's* Anat. p. 135.

TOE, in the manege, is the ſtay of the hoof upon the fore-part of the foot, comprehended between the quarters.

We commonly ſay the *Toe* before, and the heel behind, in French, *Pince devant et Talon derriere*; implying, that in horſes, the *Toe* of the fore-feet is ſtronger than the *Toe* of the hind-feet: And, on the other hand, that the heels behind are ſtronger than thoſe before; and accordingly, in ſhoeing we drive higheſt in the *Toes* of the fore-feet and in the heels of the hinder feet. See the article DRIVE.

A horſe that does not reſt his hinder feet all equally upon the ſhoe, but raiſes his heels, and goes upon the *Toes* of his hind-feet, is called in French *Rampin*. See the article RAMPIN.

TOGA *Picta*, among the Romans, a purple gown embroidered with gold; which was worn during the ſolemnity of a triumph, by thoſe who had that honour conferred on them. It was an antient habit of the Etruſcans, and not brought to Rome till after *Tarquinius Priſcus* had ſubdued the twelve ſtates of that nation. *Hoſm.* Lex. univ. in voc. *Picta*.

TOGOCH, in zoology, a name uſed by many for the umbla minor, or red charre, a fiſh caught in the lakes of Wales. The name is originally Welch. See the article CHARRE.

TOGULA, among the Romans, a narrow kind of *Toga*, uſed by the poorer ſort of people. See the article TOGA, *Cycl.* & *Suppl.*

TOKENS, in peſtilential caſes, thoſe livid ſpots which appear in the ſeveral ſtages of the diſeaſe, and are the certain forerunners of death. They generally appear only under the moſt deſperate circumſtances, and when the patient would otherwiſe be declared dying; but Hodges gives us inſtances where they appeared before any other ſymptoms of the diſeaſe, and came out without any pain or trouble; yet even in theſe caſes the perſon always died. Theſe *Tokens* are the mark by which the ſearchers conclude of the cauſe of the death of the perſon, and are the rule for ordering the houſe to be ſhut up, to prevent the ſpreading the diſeaſe. But the nurſes, and other crafty people have a way of diſguiſing this ſymptom after death, by covering the body with wet and cold ſheets. Theſe ſtrike in the ſpots, ſo that the perſon may be thought to have died by ſome other diſeaſe. *Hodges* de Peſt.

TOLCESTER, *Tolceſtrum*, in our old writers, an old exciſe or duty paid by the tenants of ſome manors to the lord, for liberty to brew and ſell ale. *Blount*.

TOLLENON, among the Romans, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another more than twice as long, and moveable upon a center. On one end of this croſs-beam were placed a covering of hurdles or planks, within which a few ſoldiers were put, and, by pulling down the other end with ropes, theſe were raiſed above the walls of a beſieged town. See *Pitiſc.* in voc.

TOLLENON, was alſo an engine for raiſing water out of a draw-well. *Pitiſc.* in voc.

TOLLES, or TOLÆ, names given by ſome to the tonſils, and by others to the glandular abſceſſes ſometimes affecting the limbs.

TOLSEY, in our old writers, denotes the place where merchants meet in a city or town of trade. *Blount*.

The word is compounded of the Saxon *Tol*, *tributum*, and *ſee*, *ſedes*.

TOLT, in law, a writ whereby a cauſe depending in a court-baron is removed into the *County-court*. Old. Nat. Br. 4. And as this writ removes the cauſe to the *county-court*, ſo the writ *pone* removes a cauſe from thence into the court of common-pleas, &c. *Terms of Law*, *Blount*, *Cowel*.

TOLTERCAIZTLI, in natural hiſtory, the American name of a ſtone, much reſembling the novacularum lapis, but variegated with red and black ſpots. They uſe the powder of this ſtone and cryſtal calcined together for diſeaſes of the eyes.

TOLUIFERA, in botany, the name of a genus of plants, ſo called from producing the balſam of Tolu. The characters are theſe: The perianthium conſiſts of one leaf, and is of a campanulated form, divided into five ſegments, and having one angle more remote than the others. The flower is compoſed of five petals, which are inſerted into the cup; four of theſe are ſtrait and equal in ſize, and are a little longer than the cup; but the fifth is twice as large as theſe, and is cordated at the end, and has an unguis of the length of the cup. The ſtamina are ten very ſhort filaments, but the antheræ are of the length of the cup, or ſomething more than that. The germen of the piſtil is oblong; there is ſcarce any ſtyle, and the ſtigma is acute. The fruit and ſeeds are yet unknown. *Linnæi* Gen. Plant. p. 182.

TOMATO, the Portugueſe name for the fruit of the lycoperſicon, or love-apple; a fruit cultivated in gardens for the ſingularity of its appearance, and eaten either ſtewed or raw by the Spaniards and Italians, and by the Jew-families in England. See the article LYCOPERSICON.

TOMBAC, a name given by the French to a yellow metal, very nearly approaching to what we call prince's metal, and made by mixing and fuſing together a large quantity of zink with a ſmaller of copper.

TOMEION, a general name uſed to expreſs any ſharp or cutting inſtrument, uſed either in ſurgery, or in the mechanic arts.

TOMENTOSE-*Leaf*, among botaniſts. See the article LEAF.

TOMIAS, Τόμιας, in antiquity, an appellation given to the ſacrifice offered at the ratification of ſolemn leagues.

It was ſo called becauſe they cut out the teſticles of the victim, and took the oath ſtanding upon them. *Potter* Archæol. Græc. T. 1. p. 252.

TOMIN, in our old writers, a weight of twelve grains, uſed by goldſmiths and jewellers. *Blount*.

TOMINEIO, in zoology, a name by which ſome authors have called the guainumbi, or humming bird, the ſmalleſt of all birds. *Joſeph Acoſta*, Ind. Occ. L. 4. c. 37. See the article GUAINUMBI.

The name ſeems derived from the Spaniſh *Tomino*, a grain weight, as if they would call it a bird of a grain weight.

TOMOTOCIA, a word uſed by ſome authors, to expreſs the Cæſarean ſection.

TONE (*Cycl.*)—TONE, *in Muſic*. The word *Tone* is taken in four different ſenſes among the antients: 1°. for any ſound. 2°. For a certain interval, as when it is ſaid the difference between the diapente and diateſſaron is a *Tone*. 3°. For a certain *locus* or compaſs of the voice; in which ſenſe they ſaid the Dorian, Phrygian, Lydian *Tones*. 4°. For tenſion; as when they ſpeak of an acute, a grave, or a middle *Tone*. *Wallis's* Append. ad Ptolem. Harm. p. 172.

In tempered ſcales of muſic, the *Tones* are made equal, but in a true and accurate practice of ſinging they are not ſo. Dr. *Pepuſch*, in Phil. Tranſ. N°. 481. p. 274.

It is uſual in the modern practice of muſic to divide the *Tone*, whether major or minor, into two *ſemi-Tones*. But a late learned muſician contends, that the diviſion of the *Tone-major* is harſh and in-elegant; ſo that, in dividing the fourth into its different ſpecies, the *Tone-major* ought either to be an individed interval, or make part of one. Phil. Tranſ. ibid See the article SPECIES.

According to Mr. Euler, the *Tone* contains two *ſemi-Tones*, taken in a large ſenſe; that is, including the greater and leſſer limma, under the term *Tone*. Thus the *Tone-major* is the ſum of the *ſemi-Tone major* and leſſer limma; as alſo the ſum of the leſſer *ſemi-Tone*, and greater limma. See the article LIMMA. And the *Tone-minor* is the ſum of the greater and leſſer *ſemi-Tones*. Laſtly, the greateſt *Tone*, *Tonus maximus*, is the ſum of two greater *ſemi-Tones*. *Euler*, Tentam. Nov. Theor. Muſ. p. 109.

But what Mr. Euler calls *Tonus maximus*, is more commonly known by muſicians under the name of a diminiſhed third. For thus they call the interval, for inſtance, between G♯ and B♭; it being compoſed of two diatonic intervals G♯ to A, and A to B♭. Vid. *Broſſard*. Dict. Muſ. p. 179.

TONE-*Major*—Six *Tones-major* exceed the octave by more than a comma. *Euler*, Tent. Nov. Theor. Muſ. p. 108.

TONGUE (*Cycl.*)—The *Tongue* is generally eſteemed a neceſſary organ in ſpeaking, ſwallowing, and taſting, yet a woman, who loſt her *Tongue* entirely by a cancer when four years old, ſpeaks diſtinctly, ſings prettily, ſwallows eaſily, and taſtes accurately. Phil. Tranſ. N°. 464. §. 11.

And this inſtance is not ſingle. Another occurs in *Lamberti's* Memoirs; and a third, in the Memoirs of the Academy of Sciences.

TONGUE-*tied*, the popular name for a diſtemperature of the *Tongue* in children, when it is tied down too cloſe to the bottom of the mouth, by a ligament connected all along its middle, and called its frænulum, which requires to be divided, to give the *Tongue* its proper motion.

This is ſometimes the caſe in adults, but oftner in children, who cannot then exert their *Tongues* to ſuck. This is however, by no means ſo common as the women uſually imagine; nor ſo much as one child in a thouſand being afflicted with it; nor is the operation in cutting it of little conſequence, ſince often bad accidents follow it, and ſometimes the loſs of a child's life. When the infant can put its *Tongue* out of its mouth, the frænulum wants no inciſion; but when the *Tongue* cannot be extended beyond the teeth, the operation is neceſſary. *Heiſter's* Surgery, p. 466. *Heildan*. Cent. 3. Obſ. 28.

To perform this, the end of the *Tongue* ſhould be covered with a linnen rag, and held with the fingers to prevent its ſlipping, and the ligament of the *Tongue* running between the ranular veins and internal ſalival ducts, is to be divided by a pair of obtuſe pointed ſciſſars, till it give room enough for ſucking or ſpeaking, but in doing this great care muſt be taken not to wound the ſalival ducts, or the proper veins and arteries of the *Tongue*; for children have been known to periſh upon the ſpot from the cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers as ſoon as a child is born; but this is a dangerous and bad practice.

TONGUE *Wounded*. The *Tongue* is frequently bit in fits of the epilepſy, and in violent falls; and is ſometimes wounded by a bullet.

If the wound is not very large, it will eaſily heal by the application of oil of almonds and ſugar-candy mixt together, or of honey of roſes and oil of myrrh made *per deliquium*; but large wounds of the *Tongue* will not unite without the aſſiſtance of the ſuture. It is therefore no wonder that wounds near the root of the *Tongue* always leave a fiſſure in the part, ſince their ſituation does not allow the uſe of the needle. To prevent the loſs of ſpeech enſuing upon large wounds on the fore part of the *Tongue*, the divided parts ſhould be brought together with the needle as ſoon and as neatly as poſſible, and afterwards anointed with oil of almonds and ſugar-candy, or honey of roſes and oil of myrrh; ſince ſticking plaſters cannot take place here. Gun-ſhot wounds on the *Tongue* can only be healed with theſe unctions, ſince the future can be of no uſe in them: the patient ſhould be kept from talking, and live upon ſpoon-meats during the cure, but more particularly at the time when the wound is about to unite. *Heiſter's* Surg. p. 81.

TONGUE *of Fiſhes*. All fiſhes have either a perfect *Tongue* or the rudiments of one in their mouths; but this organ is very different in the various ſpecies, in its figure, mobility, and other qualities and properties: as to the figure, it is in ſome pointed before, as in the clupeæ; in others it is rounded in this part, as the pearch and clariæ have it. And in others it is ſomewhat bifid, as in the pike. In ſome it is ſmooth on the upper part, as in the gadi, cyprini, and mackrel; in others it is rough and dentated in this part, as in the ſalmon, mullet, &c. In many fiſh the *Tongue* is immoveable adhering firmly to the bottom of the mouth, as in the pearch, cyprinus, and indeed in the greater part of fiſhes; in others it is looſe, as in the whale.

In the cetaceous fiſhes the *Tongue* being looſe, as in quadrupeds, it is uſed by the animal in the ſame manner; but in other fiſhes it is of no uſe in the moving the food about in the mouth, nor is it the genuine organ of taſte, being in many of a cartilaginous ſubſtance, and therefore not proper for receiving the notices of that ſenſe. The principal uſe of the *Tongue* in theſe fiſh, ſeems to be in its ſerving as an aſſiſtant organ of ſwallowing, its being more elevated than the other parts of the mouth, rendering it fit for the toſſing the food down the throat. The true uſe of the *Tongue* in thoſe fiſhes which have it dentated, is that it ſerves to retain the prey from running out of the mouth, and afterwards in the ſwallowing it; what renders them the more fit for this uſe is, that, they have always the prickles turning inwards. It is the opinion of Mr. Ray, that the *Tongues* of the cartilaginous kinds have ſome ſenſe of taſte, and this is more probable, than that the more hard and rigid ones ſhould have any ſuch ſenſe. *Artedi*, de Piſcib.

It is but of late, that we have known enough of the anatomy of ſea-animals, to be able to refer to their proper origin many of the foſſile bodies which belonged once to them: an eminent inſtance we have of this in the *Tongue* of the fiſh called the *paſtinacha marina* by compariſon with which Sir Hans Sloane explained the nature of a very elegant foſſil, found ſometimes with us, but oftner in the Eaſt-Indies, ſometimes in the Weſt, and every where till then ſuppoſed to be a petrified muſhroom. The paſtinacha marina is a fiſh of a flat ſhape, and allied to the thornback kind. The *Tongue* of this fiſh is made up of many bones, all of them crooked, their two ſides making an obtuſe angle, ſuch as the ſides of the under mandible of a man do.

The uppermoſt ſides of theſe ſeveral bones, have furrows and pieces ſtanding together, after the manner of the teeth of a ſhort ſmall-toothed comb, or ſomewhat reſembling what we call the gills, on the under ſide of a common muſhroom; and to this furrowed appearance in the foſſile pieces, was owing the general error of taking them to be of the fungus kind. The extant parts of theſe toothed points in the *Tongue* anſwer to the like parts in the bones of the upper jaw of this fiſh; and between theſe and this bony *Tongue*, the food of the fiſh is cut and ground to pieces. The under ſide of the *Tongue* is, in the ſame manner as the upper, divided into ſeveral crooked pieces; but theſe have in this part no teeth or points: the whole *Tongue* of this fiſh is ſometimes found foſſile, converted into a ſort of ſtone, but this more frequently happens to the ſeveral joints or ſingle bones of which it is compoſed, and theſe are often mutilated or broken. The palate of the ſame fiſh is alſo ſometimes found either whole or in parts, and both the one and the other are of the number of thoſe things, called by Mr. Lluyd *ſiliquaſtra*, from a ſuppoſed reſemblance in them to the pods of the lupine, or ſome other ſuch plant; but he has diſtinguiſhed theſe from the reſt by calling them *ſiliquaſtra pectinata*, or the comb-like ſiliquaſtra. Phil. Tranſ. N°. 230.

TONGUE *of a Muſcle*. What is vulgarly called the *Tongue* in this fiſh from its ſhape, is truly an organ by means of which it ſpins a ſort of threads in the manner of ſpiders or caterpillars; to fix itſelf to the rocks by. See the article MUSCLE.

TONGUE, in the manege. The aid of the *Tongue* or voice, is a ſort of agreeable clacking, or a certain ſound formed by the cavalier, in ſtriking his *Tongue* againſt the roof of his mouth, when he means to animate the horſe, and ſuſtain him, and make him work well in the manege. See the article AID.

To ſwallow the TONGUE, in the manege. A horſe is ſaid to draw in or ſwallow his *Tongue*, when he turns it down his throat, which makes him wheeze as if he were ſhort winded. This fault is cured by giving him a bitt with a liberty for the *Tongue*. See the article LIBERTY.

TONICUM *Diatonum*. See the article GENUS.

TONOS, a word uſed by Hippocrates to expreſs in general any nerve, whether ariſing from the brain or ſpinal marrow. It is alſo uſed to expreſs a tenſion in any part.

TONSÆ, among the Romans, the blades of oars, or that part of them which beats againſt the water. *Pitiſc.* in voc.

TONSILLS (*Cycl.*)—*Inflammation of the* TONSILLS. This is a very common complaint from taking cold, and in its different degrees requires different methods of cure: in general the ſame means are to be uſed as in quinſeys, except that ſuch copious bleedings are not neceſſary; nor indeed is there occaſion for bleeding at all unleſs the patient is of a plethoric habit, or the inflammation be very violent, for in that caſe, the taking away a moderate quantity of blood often prevents its coming to ſuppuration. The patient is firſt to be purged with an infuſion of tamarinds, ſena, and cream of tartar, and this repeated to the third or fourth doſe, if there be occaſion; in the intermediate times, the diaphoretic attemperating and nitrous medicines are to be given in powders, and a large quantity of diluting liquors allowed, which ſhould be gently acidulated, and have a ſmall quantity of nitre diſſolved in them. Gargariſms made of decoctions of biſtort root, red roſes, and other gentle aſtringents, are to be frequently uſed; and the frequent waſhing the feet in warm water often has a very remarkable good effect.

If after four or five days the diſtemper is found not to give way to theſe means, but the tumour ſtill remains; there is then but little hopes to be had of its reſolution, and a very different end is to be attempted; emollient gargariſms are now to be uſed and maturating plaſters externally applied, ſuch as diachylon with the gums, and the like; and ſuppurating cataplaſms are to be applied to the whole neck and throat: theſe methods are to be continued till the tumour either burſts of itſelf, or is ſo ripe as to be fit for opening by the hand of the ſurgeon. After this has been done, and the matter is diſcharged, gargariſms muſt be uſed of decoctions of ſome vulnerary herb, or common green tea, ſweetened with honey of roſes, may be uſed to ſerve the purpoſe. The mouth and throat are to be frequently waſhed with this till the part is healed. It is to be obſerved, however, that the reſolution of theſe tumours is never to be deſpaired of, not even during the uſe of the ſuppurating medicines, for it is often ſeen that the tumour has been wholly diſcuſſed even during the uſe of theſe means, the reſolution often being extremely ſlow.

This is a very troubleſome complaint, and with ſome perſons is apt to return very frequently; the beſt preſervative againſt it is a moderate diet and bleeding about the time of the equinoxes, either in the arm or foot. Some have found it neceſſary to open an iſſue in the arm, in this caſe, and have been by this means perfectly cured, but on its drying up have always found the diſeaſe return. *Heiſter's* Compend. Med. p. 131.

TOOTH-*Ach* (*Cycl.*)—When this terrible pain will give way to no other remedy, it is ſaid it may be ſpeedily removed by cauterizing behind the ear underneath the protuberance termed antitragus. There are ſeveral methods of doing this: ſome uſe a cautery prepared on purpoſe, others only a common ſmall iron nail, or a piece of iron wire, and others heat a ſcalpel red hot and plunge into the part; others alſo affirm that as much ſervice is to be done by cutting there without cauterizing, ſuppoſing that the operation deſtroys a nerve going thence to the *Tooth*, which is the occaſion of the ſenſe of pain in it. But it is to be doubted whether this ſevere remedy be as certain of ſucceſs as ſome pretend. *Heiſter's* Surgery, p. 434.

TOOTH-*drawing*. *Tooth-drawing* according to Cicero was invented by Eſculapius, in whoſe temple the antients hung up a pair of leaden pullicans, very properly ſignifying that no *Teeth* were fit to be pulled out, but ſuch as might be removed with a leaden forceps; that is ſuch as were looſe and ready to fall out of themſelves; for they very little conſult their own welfare, who pull out their *Teeth* while firm and ſound: for drawing the *Teeth* is not only a painful operation, but often brings on bad accidents, and ſometimes even hazards the patient's life.

Tooth-drawing, however wrong in many cafes, yet is certainly right and neceffary in others. 1. In children for the removing their lacteal or deciduous *Teeth*, for when thefe are left too long in their fockets, they difplace the new ones and turn them awry. 2. In infants it is alfo neceffary to draw fuch *Teeth* as grow out of the palate, or out of improper parts of the mouth, and are placed fo as to impede theirfpeaking or fucking. 3. In the *Tooth-ach* proceeding from a *Tooth's* being carious, and giving way to no medicines, drawing is the laft refort, and is abfolutely neceffary. 4. Thofe *Teeth* ought to be drawn which by their irregular figure and pofition lacerate the gums and lips, and cannot be brought into fhape by the file. And laftly, it is fometimes neceffary to draw a *Tooth* for the curing a fiftula, or ulceration of the gums near the roots of the *Teeth*.

The regular method of drawing them is this: If the *Tooth* is in the lower jaw, the patient muft be feated on a low feat, or on the floor, and if in the upper jaw, he muft be placed on a high ftool or table; then the proper inftrument is to be felected, and the *Tooth* carefully drawn as a nail out of a piece of wood. But this muft never be done while the gums are inflamed, fwelled, or otherwife diftempered. *Heifter's* Surgery, p. 456. See alfo *Fauchard's* Chirurgien Dentifte.

Wolf-Tooth. See the article Wolf.

Tooth-*Wort*, in botany. See the article Plumbago.

TOP (*Cycl.*)—Top *of a Ship*, a round frame of boards lying upon the crofs-trees near the head of the mafts, here they furl or loofe the *Top*-fail, &c.

Top-*Armours*, in a fhip of war, are a kind of cloths hung about the round-*Tops* of the mafts for fhow; and alfo to hide the men which are in the *Top* in a fight, who lie there to fling ftink-pots, &c. or to fire fmall fhot down on the enemy in cafe of boarding.

Top-*Mafts*, in a fhip are four, which are made faft and fettled unto the heads of the main-maft, foremaft, mizzen-maft, and bow-fprit refpectively.

Top-*Gallant-Mafts*, in a fhip are two, *viz. main-Top-gallant-maft*, and *fore-Top-gallant-maft*, which are fmall round pieces of timber, fet on their refpective *Top-mafts*; on the top of which mafts are fet the flag-ftaffs, on which the colours, as flags, pendants, &c. hang.

Top-*Ropes*, in a fhip, are thofe with which the *Top-mafts* are fet or ftruck. They are received through a great block, which is feized on one fide under the cap, and then are reeved through the heel of the *Top*-maft, where is a brafs fhiver placed athwart fhips; after this they are brought up and faftened on either fide the cap with a ring: the other part of them comes down by the ties, and fo is reeved into the knight-head; and when it is to be heaved, it is brought to the capftan. Thefe *Top-ropes* belong only to the main and fore-maft.

Top-*Sail-Lifts*, on board a fhip. See the article Lifts.

Top-*Sails*, and Top-*Gallant-Sails*, in a fhip, are thofe belonging to the *Top*-mafts, and *Top*-gallant-mafts.

Top-*a-Starboard*, on board a fhip, the word of command to hale upon the larboard lift.

Top *the Yard-Arms*, on board a fhip, a word of command to make the yards hang higher or lower. See the article Yard.

TOPAN, in zoology, a name by which fome have called the horned-beaked Indian raven, more ufually known by the name of the rhinoceros-bird, *Worm.* Muf. p. 113. See the article Rhinoceros-*Avis*.

TOPAZ, Topazius. The name given by the moderns to a gold-coloured gem, called by the antients the chryfolite, or gold-coloured gem.

This is a very valuable and beautiful gem, when pure and in its moft perfect ftate, but fuch are very rare; and the lefs perfect ones common among our jewellers are of little beauty or price.

The *Topaz* is never found very large; the far greater number of the oriental ones are as fmall as the head of a large pin, and it is but here and there one, which arrives at the fixth of an inch diameter, and very few indeed exceed that ftandard. The American ones are fomewhat larger than thefe, and the European are the largeft of all; but of the leaft value. It is always found in a pebble-like form; roundifh or oblong, and flatted on one fide, and of an irregular and uneven furface, but ufually bright and of a good natural polifh, unlefs where fouled by accidents. It is never found in a columnar or cryftal-like form, notwithftanding that our dealers in gems carry on a large trade with what they call *Topazes*, which are of this fhape: but all thefe when brought to the wheel are found to be no more than common cryftals, accidentally tinged to a yellow colour, as is very common for the cryftals and fpars to be, in and about mines, from an admixture of metalline particles; and almoft all the common *Topazes* worn in rings are of this falfe kind.

The colour of the *Topaz* is ever a pure yellow; but, like the other gems, it has this in very different degrees: the fineft *Topazes* are of a true and exact gold-colour, and are of great fplendour; but they vary from this in degree, up to the deepeft faffron-colour, and down to that of the paleft amber.

The fineft *Topazes* are of equal hardnefs with the ruby and fapphire, and are fecond only to the diamond; from this they degenerate down to the hardnefs of a garnet, and yet lower; but in all the genuine *Topazes*, even the very meaneft are, when brought to the mill, found to be much harder than cryftal. The fineft *Topazes* have a luftre at leaft equal to any gem except the diamond; but the others are but dead and heavy: the oriental ones divefted of their colour, by putting them in the fire, make a very clofe counterfeit.

The *Topaz* is found in the Eaft and Weft-Indies, and in many parts of Europe: the oriental are greatly fuperior to thofe of any other part of the world; and the American are not much better than the German. The fineft gem of this kind ever known, is in the poffeffion of the Great Mogul; its weight is faid to be 157 carrats, and its value more than twenty thoufand pounds. *Hill's* Hift of Foff. p. 598. feq.

Counterfeit Topaz. To counterfeit the oriental *Topaz* in pafte: Take cryftal prepared two ounces, ordinary minium or red lead feven ounces; put thefe into a crucible luted, and bake them twenty-four hours in a potter's kiln. If the mafs is not fufficiently clear and fine, cover it up again and give a fecond baking, and it will come out of a fine *Topaz*-colour. *Neri's* Art of Glaff. p. 131.

TOPE, in ichthyology, an Englifh name for a fpecies of the fqualus according to the Artedian fyftem, diftinguifhed from the other fquali, by the noftrils being placed extremely near the mouth, and by certain foramina, or apertures near the eyes. It is the fifh called by the antients γαλεὸς κύων, *galeus canis* and *canicula*. See the article Galeus *Canis*.

TOPIARIA, in botany, a name by which fome authors have called the acanthus, or bear's breech, a plant common in the gardens of the curious. *Ger.* Emac. Ind. 2.

TOPICS (*Cycl.*)—*Topics* are fuch medicines, as by the fmallnefs and mobility of their particles, attended for the moft part with a gentle acrimony, are able to make their way into the fubftance of the parts to which they are applied, without eroding or wounding any of the folids; and thence are juftly called penetrating *Topics*.

It may be a queftion how *Topics* in medicine act. It is commonly faid that this or that medicine penetrates the pores; but the ideas annexed to fuch expreffions do not feem very diftinct. Writers on this fubject have feldom been at the pains to tell us what pores they mean. We have an effay on this fubject in the Medic. Eff. Edinb. Vol 2. Art. 4. by Dr. Armftrong, who thinks that the effects of fuch medicines are not owing to their particles entering the orifices of the abforbent veins; nor to the opening of the exhalent veffels on the furface of the body by thefe medicines; nor will he allow the particles of penetrating *Topics* to force their way through the coats of the veffels; but he fuppofes, that fubtile medicines are conveyed by the exhalant veffels of the fkin, to thofe parts of the fmaller arteries, where the circulation is choaked by obftruction.

Topic, in rhetoric. See the article Locus.

TOPPING *the Lifts*, aboard a fhip, the fame as haling the top-fail-*lifts*, and therefore they fay *top-a-ftarboard*, or *top-a-port*, that is, hale upon the ftar-board, or larboard lift. See the article Lifts.

TORCH-*Thiftle*, *Cereus*, in botany, a fpecies of plants belonging to the *Cactus*-genus. See the article Cactus, Append.

This plant confifts of a fingle ftem or body, twenty, thirty, or more feet high, and about five inches in diameter. It is of an angular figure, and armed with clufters of fharp firm fpines, growing from tubercles placed along the ribs. The flowers, when open, are of the fize of a large rofe, and confift of forty or more petals; the outer ones purplifh or greenifh, the inner ones white.

It is a native of Surinam, and many parts of fouth America. It has gotten the name *Torch-thiftle*, from its being much ufed for *Torches*.

This plant is frequent in our ftoves among the curious in exotic vegetables, but it fo rarely flowers, that many who have kept feveral fpecies of it in their ftoves for their whole lives, have not happened to fee it. Dr. Trew gives a particular account of the flowering of one of thefe plants, at Nuremberg, in the year 1730; which may be agreeable to the curious, who have not themfelves feen it.

The plant which flowered there was a branch feven years before feparated from another *Cereus* in the fame garden, which had never flowered. It had in this time grown to be fix foot high, and thirteen inches thick: it had feven angles near the bafe, eight in the middle, nine near the top. Its upper part appeared of a bluifh green, from a dufty matter it was covered with; its lower part was of a fine grafs-green, and the down of the prickles was whitifh near the top, and every where elfe brown. On the fifth of September, within an inch of its top, their appeared a round knot growing out of the trunk, this increafed in fize very faft and grew out horizontally, on the fourteenth of the fame month, it was eight inches long, and plainly fhewed the rudiments of a flower, tho' as yet clofed up, and fome elegant ftains of green, purple, and white were vifible on it.

The fame evening the flower began to open, and at midnight was fully expanded, it was then fix inches in diameter, and was of a ftrong but not pleafant fmell. After midnight it began to contract; it grew lefs by half an inch in a few hours, and remained of this fize till the next day at noon; it then foon con-

contracted to half its former diameter, and the next morning it was quite closed and withered, but it hung on the trunk till the thirtieth of September.

The beginning of the flower is a sort of tube, three inches long and about an inch diameter; of a colour between a yellow and a pale green: Its surface is channelled with several small furrows, between which there ran several blunt protuberances in a parallel order along the ridges; where the tube expanded itself, it divided into more than forty petaloide segments, ranked in six separate series; the three exterior and inferior whereof, here and there confounded their order, while the three superior and interior remained separate and unmixed. These several series differed in size and colour, the first or exterior series was of the same colour with the tube, that is of a pale yellowish green, but its upper part gradually inclining to purple. The second and third series had half their inner part greenish, and their edges of a more intense purple; the fourth was between yellow and white, terminating in purple tops; the tops of the fifth were likewise purplish. The petaloide segments of the sixth series were very tender and white, all the segments were of an oblong figure, and in the first series were terminated with blunt tops, in all the others with more and more pointed ones to the very innermost series. The innermost series, which contained thirteen of these segments, had all their edges lightly and irregularly cut and divided: the pistil was of equal height with the surface of the flower, and was a hollow tube, terminating at its upper part in a number of fine tender filaments, expanded in the form of a crown; these were as many in number as the segments of the innermost series, that is thirteen. The day before the flower dropped from the ovary, the place where it was to fall off was marked with a blackish circle, and at this the tube readily and evenly separated from the rudiments of the fruit. The pistil still firmly adhering to the ovary: the petaloide segments of the flower were found not be separated from the tube without tearing, and were really segments, not distinct petals as might have been guessed by a cursory view of the flower. The fruit did not come to its full growth, but grew so far as to shew that it would never have been prickly: upon dissection it afforded a viscous juice, and within it was a cavity, the sides of which were every where beset with small villi, except at the bottom; and at the end of each of these hairs hung a small white vesicle which was the rudiment of a future seed. The error of the common opinion of supposing the flower of the *cereus*, polypetalous, is evident from this description, and all that is observed of this strange and elegant flower, has been since verified by the flowering of the same species with us. About six years ago I was on a visit at the late Lord Petres at Therndon in Essex, when his gardener, who had been some time ordered to watch a *cereus* of this species which was about to flower, called us out at midnight to see it. It had opened three flowers at different heights upon the stalk, and they were all of the same size, something larger than the standard given by Dr. Trew, but in all other respects perfectly agreeing with his description. Philos. Trans. N°. 416.

The propagation of all the kinds of this remarkable plant is by cuttings, which must be laid in a dry place ten days or a fortnight before they are planted, or if it be three weeks, there is less danger of their miscarrying. They are to be planted in small pots, filled with a light sandy earth, with a mixture of lime rubbish, laying some stones at the bottoms of the pots to drain off the moisture. The pots are then to be placed in a gentle bed of tanner's bark, and once a week are to have a gentle watering; this is best done in June, or July: toward the middle of August, they must have air given them by degrees, and at the end of September they must be removed into the stove, where they are to remain the winter. They should always have a dry situation, and should never be exposed to the open air even in the midst of summer. When the top of an old plant has been cut off for propagating; it always throws out several young shoots from its angles, which may all be easily propagated in the same manner, and it will continue to do this in such a manner, that there will be a continual supply even from one stock. They may be brought in small pieces from the West Indies packed up in straw, and will grow when planted here, as well as if cuttings from our own plants. *Miller's* Gardener's Dict.

TORCHENES, in the manege, a long stick with a hole at the end of it, through which a strap of leather is run, the two ends of which being tied together, serve to straiten and closely tie up a horse's nose as long as the stick is stayed upon the halter or snaffle. This is done to keep the horse from being unruly, when he is dressed, or upon any other occasion.

TORDINO, in zoology, a name by which the Venetians call a bird of the lark kind common in their markets, and called by authors *spipolletta*. See the article SPIPOLETTA.

TORDO *Marino*, in zoology, the name of a bird of the starling-kind, called also the *codirosso maggiore*, or *ruticilla major*, and by the Austrians the *stein-reitling*. Aldrovandus has named it the *merula saxatilis*, or rock-blackbird. It is of the size of our starling, and much resembles it in figure, its breast is greyish and has a black transverse streak, and behind that the whole is of a yellowish hue. Its head and back are of a blackish hue with some slight variegations of grey, from the tip of the feathers being of that colour. The tail is long and of a reddish orange colour, and the under feathers of the wings are of the same hue; the females are of a less elegant colour than the males, viz. a mouse-colour variegated with white on the back, and ash-colour on the belly; what is yellow in the male birds is also very pale in the females. It is not uncommon in Germany, and may be taught like the starling to imitate the human voice. *Ray's* Ornitholog. p. 145.

TORDYLIUM, in botany, the name of a genus of umbelliferous plants; the characters of which are these: The flowers are of the rosaceous kind, being composed of several heart-fashioned petals of irregular sizes disposed in a circular order on a cup which afterwards becomes a fruit nearly of an orbicular figure, being composed of two flattish seeds with a high and usually denticulated margin, which easily deposit their covering.

The species of *Tordylium* enumerated by Mr. Tournefort are these: 1. The greatest *Tordylium*, called by some the largest *caucalis*. 2. The smaller Narbone *Tordylium*, called by some the smaller Cretic *seseli*. 3. The least Apulian *Tordylium*, called the least *seseli*. 4. The small Syrian *Tordylium* with a granulated limb, called by some *gingidium*, and the great seeded *caucalis*. And, 5. The Portugal *Tordylium*, with hemlock-leaves, and striated seeds. *Tournef.* Inst. p. 320.

TORMENTILLA, *Tormentill*, in botany, the name of a genus of plants, the characters of which are these: The flower is of a rosaceous kind, consisting of four leaves disposed in a circular form: the cup is of the shape of a bason, consisting of one leaf, divided into several segments; the pistil arises from this cup, and finally becomes a globose fruit composed of several seeds closely laid together, and covered by the cup.

To these it may be added, that the leaves grow always more than three together, at the ends or summits of the stalks.

The species of *Tormentill* enumerated by Mr. Tournefort are these: 1. The common wild *Tormentill*. 2. The large Alpine *Tormentill*. 3. The creeping *Tormentill*, with gold yellow flowers. 4. The great *Tormentill*, with green deeply divided leaves. 5. The lesser *Tormentill*, with leaves deeply indented. *Tournef.* Inst. p. 298.

TORMENTILLÆ *radix*, in the materia medica, is the root of the common wild *Tormentill*, which is frequent with us in woods and on heaths, and flowers in June and July. It is a small trailing plant, and the leaves grow about seven at a joint; the flowers are small but of a lively yellow; the root is tuberous and often an inch thick, brown or reddish without, and of a flesh colour within, of a very astringent taste, and are to be chosen from the druggists large, plump, fresh dried. It is a cordial and a very valuable astringent; it makes a very good addition to the common white drink, changing it to a red colour and increasing its virtue. *Pomet's* Hist. of Druggs, p. 48.

TORPEDO, (*Cycl.*) the *cramp*, or *numb fish*, in ichthyology, a name given to that species of ray-fish which is wholly smooth. See the article RAJA.

The phænomena of this fish are fully explained in the cyclopædia under the article TORPEDO.

TORQUATA, in zoology, a name given by many authors to the common or water-snake, from the remarkable ring it has about its neck. See the article NATRIX.

TORQUILLA, in zoology, the name of a species of woodpecker, more commonly known by the name jynx, and called in English the wry-neck, from its manner of twisting its neck about, and turning its head over its shoulders. *Ray's* Ornitholog. p. 95. See the article JYNX.

TORTOISE (*Cycl.*)—It is said *Tortoises* will live some days after their heads are cut off, and that this is a preparation for dressing them in Pegu. *Boyle's* Works Abridg. Vol. I. p. 28. See the article TESTUDO.

TORTURA, a word appropriated by many medical writers, to express only the distortions of the face, and particularly of the mouth in convulsions.

TORUS, in architecture. See the article TORE, *Cycl.*

TORUSCULA, a word used by some medical writers to express a drop.

TORYNE, in pharmacy, the name of a kind of spatula intended for the stirring up the ingredients of decoctions while boiling.

TORYNETOS, a name given by some to a mixture of bread and water boiled together, whether meant as a kind of a panada, or for a pultice.

TOTANO, or TOTANUS, in zoology, the name of a bird, of the ægocephalus or godwit kind, common in the Italian markets, and more usually known by the name of vetola. See the article VETOLA.

TOTANUS, is also used by some for the limosa. See the article LIMOSA.

TOTAQUESTAC, in zoology, the name of a beautiful American bird, described by Nieremberg from Antonius Herera. It is said to be something smaller than a pigeon, and all over of a most beautiful green; its tail-feathers are of a very great length, and are greatly esteemed. The Indians value the bird so highly that it is death by their laws to kill it, so that when it is caught they only strip it and let it go again. *Ray's* Ornithol. p. 303.

TOTTAVILLA, in zoology, a name by which ſome authors have called the *alauda arborea*, or common wood-lark. See the article ALAUDA.

TOUCAN (*Cycl.*)—TOUCAN, in zoology, the name of a very remarkable Braſilian bird, a kind of magpie, of a middle ſize between our common magpie and the thruſh, but having a beak thicker and longer than its whole body; this beak is hooked at the end, and is of a very thin ſubſtance, not exceeding the thickneſs of a membrane, and very light and hollow, yet bony in ſubſtance and very bright and ſhining. It has a ſort of toothed edge, which prevents its ſhutting cloſely, and giving paſſage for the air, enables the bird to live without noſtrils.

It is yellowiſh on the outſide and red within, and is covered with a ſort of ſcaly ſubſtance eaſily ſcraped off with a finger at the edge. Its head is large in proportion to its body, and is black on the crown, the reſt of it and the neck and back are ſlightly variegated with white; its breaſt is of a bright orange-colour, and its belly and thighs of a very fine and bright red, and the tail is black, but red at the end: it is on the whole a very ſingularly beautiful bird. It is ſaid that it feeds on pepper, and Thevet affirms that it devours it greedily and returns it again undigeſted, and that the natives gather up that pepper, and uſe it in their food, as leſs hot and acrid than the freſh pepper. See Tab. of Birds, N°. 11. and *Ray's* Ornitholog. p. 88.

TOUCH-*Hole*, or VENT, in gunnery, is the ſmall hole at the end of the cylinder of a gun or muſquet, by which the fire is conveyed to the powder in the chamber. In a firelock, carabine, or piſtol, it is called the *Touch-hole*, but in a piece of cannon it is more properly called the vent.

TOUCH-*Needles*, ſmall maſſes of gold, ſilver, and copper, each pure, and ſimple, and in all the different combinations, proportions, and degrees of mixture, prepared for the trying gold and ſilver by the *Touch*-ſtone; by compariſon with the mark they leave on it.

The metals uſually tried by the *Touch*-ſtone, are gold, ſilver, and copper, either pure, or mixed with one another in different degrees, and proportions, by fuſion. In order to find out the purity, or quantity of baſer metal in theſe various admixtures, when they are to be examined, they are compared with theſe needles, which are mixed in a known proportion, and prepared for this uſe. The metals of theſe needles both pure and mixed, are all made into laminæ or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickneſs, and an inch and half long; theſe being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The manner of making the *Touch-needles* is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into fixteen half ounces, the half ounces each into four drams, the dram into four penny-weight, and this into two half penny-weights.

Silver TOUCH-*Needles*, theſe muſt be only tempered with copper, and the proportion determined by the mark divided into half ounces and grains.

You muſt uſe therefore for this purpoſe one mark of ſuch a weight that it may conſtitute a ſufficient maſs of metal for the making one needle, let it weigh for inſtance one dram, then weigh ſuch a mark of the pureſt ſilver, wrap it up in a ſmall paper and upon this write fixteen half ounces, which will ſignify that the whole mark of this metal is the pureſt ſilver, make the firſt needle of this maſs.

Next weight fifteen half ounces of pure ſilver, and one half ounce of pure copper, wrap theſe both in a paper, and write on it fifteen half ounces, which will ſignify that there are in that ſmall maſs fifteen parts of pure ſilver, and one part of pure copper; make of this the ſecond needle. In the ſame manner go on with the reſt, add two half ounces of copper to fourteen half ounces of ſilver, mark it fourteen half ounces, make the third needle of this, and in the ſame manner proportion the ſmall maſſes of ſilver and copper for making the other needles, and put inſcriptions upon every one in the following manner.

For the needle	half oz. of ſilver	half oz. of copper.

When you have gone thus far, and have the metals in each of theſe proportions, wraped up in its ſeparate paper; put each ſeparately, into a new crucible never uſed for any operation, and adding a little borax melt them together in a very quick fire, which muſt be well kindled before with bellows: or what is yet better, throw them ſuddenly into a hot crucible, and as ſoon as they melt, ſtir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot. When this is done, wrap up each maſs, when cold, in its own paper again, and weight them ſingly, in a nice ballance. If they ſtill weigh a whole mark, they are good; but if there is any conſiderable deficiency in their weight, it is a ſign that your fire having been too weak, or of too long duration, has conſumed as much copper as is wanting in the weight; therefore this maſs muſt be eſteemed uſeleſs, and another made in its place in the ſame proportion.

When this is all finiſhed, make with a hammer out of each theſe ſmall maſſes, a *Needle*, making them a little hot; then engrave on each of theſe *Needles*, the number of half ounces it contains, as before marked on its paper; that is, upon the firſt 16, upon the ſecond 15, and ſo on, and then pierce them at one end, and running a ſilver wire thro' their eyes, collect them in order according to their different numbers. Theſe are the *Silver Touch-Needles*, made of the different allays of ſilver and copper.

In Holland they make uſe of the mint mark, divided into grains for the making their *Needles*. The firſt *Needle* made of pure ſilver is ſaid to be of twelve penny-weights. The ſecond is made of eleven penny-weights and eighteen grains, by the addition of ſix grains of copper. The third is made of eleven penny-weights and twelve grains, by the addition of twelve grains of copper; and ſo on, the proportion of ſilver decreaſing always ſix grains, that is, one quarter of a penny-weight at a time, and that of the copper being always increaſed in the ſame proportion, till at laſt the weight of the ſilver is reduced to one penny-weight, and that of the copper encreaſed to eleven penny-weights, which proportion conſtitutes the laſt *Needle*.

It is needleſs however, to go through the whole ſeries of the *Needles*, by ſo ſmall progreſſions to the very laſt, for very delicate proportions cannot be very accurately diſtinguiſhed in the operation.

Gold TOUCH-*Needles*. Theſe muſt be mixt either with ſilver alone, or with ſilver and copper, variouſly intermixed. This mixture is called allaying or carracting, and is determined with a mark divided into carracts, or weights of two ſixth parts of an ounce. There is nothing to be obſerved about the making of theſe *Needles*, beſide what has been already ſaid in regard to the *Silver Needles*; except that the proportions of the weights are determined in another manner. Theſe *Needles* are made according to the following diviſion and order; and they all weigh one mark.

The firſt is entirely of pure gold.

	pure gold	pure ſilver.
2.	23 Car. 6 Gr.	6 Gr.
3.	23 Car.	1 Car.
4.	22 Car. 6 Gr.	1 Car. 6 Gr.
5.	22 Car.	2 Car.
6.	21 Car. 6 Gr.	2 Car. 6 Gr.
7.	21 Car.	3 Car.
8.	20 Car. 6 Gr.	3 Car. 6 Gr.
9.	20 Car.	4 Car.
10.	19 Car.	5 Car.
11.	18 Car.	6 Car.

The decreaſe goes on thus, by whole carracts, till the weight of the gold is arrived at one carract, and that of the ſilver at twenty three; for after the ninth *Needle* you cannot make ſo exact a diſtinction of the half carracts.

This mixture of gold and ſilver is called the white allay; but when copper together with ſilver enters into the mixture of the gold, then it is called a mixt allay. The *Needles* for trial of pieces thus debaſed, are made of mixtures analogous to the former, except only that thoſe portions which in the firſt caſe were pure ſilver, here conſiſt of copper and ſilver mixt. Therefore you have here a double ſeries; for the mixture is either of two parts of ſilver, and one of copper, or of two parts of copper and one of ſilver. For inſtance,

The firſt is of pure gold.

	of pure gold.	of pure ſilver.	of pure copper.

8.	20 Car. 6 Gr.	2 Car. 4 Gr.	1 Car. 2 Gr.

and ſo on as in the foregoing.

If in this table you take pure copper inſtead of pure ſilver, and ſilver inſtead of copper, this gives you a third ſeries of golden *Needles*. And you may have a fourth by mixing with gold equal quantities of ſilver and copper in the ſame proportion. Theſe allays of gold are much in uſe, but workmen may eaſily employ a multitude of other variations, which compared with the already mentioned will be diſtinguiſhed in a thouſand different ways by an experienced perſon, ſo that it is neither poſſible, nor neceſſary to imitate them all.

But that theſe *golden Needles* may not be too expenſive, they

they may be made much ſhorter than thoſe of ſilver, and afterwards ſoldered to plates of copper, that may be ſufficiently long for uſe.

The uſe of theſe *Needles* is by means of the touchſtone; and ariſes hence, that every metal when pure muſt have its ſpecific colour, that diſtinguiſhes it from the reſt: but metals being the moſt opake of all known bodies, the ſpecific colour of every one appears moſt diſtinctly when you rub it againſt a very black hard ſtone; and if the colours of two or more metals are expreſſed by large lively ſpots, made near each other on the ſame plane, by rubbing them againſt the ſurface of the ſtone, you will by that means eaſily diſcern their difference, or their likeneſs.

The ſtone adapted to this uſe, and called from its office the *Touch-ſtone*, muſt have the following qualities. It muſt be of the deepeſt black, leſt the tincture of the metal ſhould be altered by ſpurious rays of light ſhining among it: it muſt be capable of being pretty well poliſhed, for when too rough, the colours of the metals rubbed againſt it cannot be neatly or regularly diſtinguiſhed; and if it is too ſmooth, the metals are but faintly, and too ſlowly abraded or ſcraped by it, eſpecially when gold is tried. It muſt alſo be neither too hard, nor too ſoft. Tripoli, coal-duſt, and tin aſhes are uſed in rubbing off the thin metalline cruſts, and in a ſhort time the ſtone when very hard is apt to acquire too ſmooth a ſurface; and when it is too ſoft it eaſily wears, throws off a duſt, and contracts furrows.

The black rough marbles, and the ſofter black pebbles from the beds of rivers, are moſt proper for this uſe, and are to be made into the form of a quadrangular priſm, about an inch thick, and two or three inches long.

The method of uſing your *Needles* and the ſtone is this: When you meet with a piece of metal to be tried; firſt wipe it very well with a clean towel, or piece of ſoft leather, that you may the better ſee its true colour; for from this alone an experienced perſon will in ſome degree judge before-hand what the principal metal is, and how, and with what debaſed.

Then chuſe a convenient not over large part of the ſurface of the metal, and rub it ſeveral times very hardly and ſtrongly againſt the *Touch-ſtone*; that in caſe a deceitful coat or cruſt ſhould have been laid upon it, it may be worn off by that friction. This however is done more readily by a grindſtone or ſmall file if you have them at hand. Then wipe a flat and very clean part of the *Touch-ſtone*, and rub againſt it over and over, the juſt mentioned part of the ſurface of the piece of metal, till you have on the flat ſurface of the ſtone a thin metallic cruſt, an inch long and about an eighth of an inch broad: this done look out the *Needle* that ſeems moſt like to the metal under trial, wipe the lower part of this *Needle* very clean, and then rub it againſt the *Touch-ſtone* as you did the metal by the ſide of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks, made by your *Needle*, and the metal under trial; you may with great probability pronounce that metal, and your *Needle*, to be of the ſame allay; which is immediately known by the mark engraved on your *Needle*. But if you find a difference between the colour of the mark given by the metal, and that by the *Needle* you have tried; chooſe out another *Needle*, either of a darker or a lighter colour than the former, as the difference of the tinge on the *Touch-ſtone* directs; and by one or more trials of this kind you will be able to determine which of your *Needles* the metal anſwers, and thence what allay it is of, by the mark of the *Needle*; or elſe you will find that the allay is extraordinary, and not to be determined by the compariſon of your *Needles*.

But if the metal under trial, has been altered by tin, arſenic, zink, or other ſuch admixtures, the workmen may be deceived by the colour, ſo as to take for pure gold, or ſilver, that which is not by any means ſuch. Deceits of this kind however are found out by the aſſiſtance of acid menſtrua. *Aqua fortis* anſwers this purpoſe, when the maſs is of the colour of gold, and *aqua regia* when it is of the colour of ſilver; for the firſt of theſe menſtrua diſſolves all metals except gold, and the latter all metals except ſilver. In this caſe then you are to pour upon your metallic ſtreak on the ſtone, one ſmall drop of either of theſe liquors, and extend it gently over it with a feather. If it is neither gold nor ſilver the whole ſtreak will be obliterated and conſumed, but if there is any gold or ſilver in it, this remains undiſſolved, and ſhews another colour, becauſe the other parts have been ſeparated from it by the ſolution. When theſe menſtrua are uſed, great care muſt be taken that there is no oil in the way; for that would ſpoil and deſtroy their effects.

Beſide theſe the following particulars are to be obſerved: Gold and ſilver when pure, whether ſeparate or both mixed together, without the addition of any other matter, when made hot in the fire, not only preſerve their colour, but if they were tarniſhed before, they recover their ſplendour there, not loſing the leaſt part of their weight: and by this quality in theſe two metals, the *caratura alba*, or white allay, made by the mixture of gold and ſilver alone, is diſtinguiſhed from all the others. If you have not liberty to try the whole maſs in the fire, you may make this experiment on a ſmall piece of it with a blow pipe.

If you find a *Needle* of the ſame allay with the metal under trial, the ſtreaks made by both upon the touch-ſtone muſt undergo exactly the ſame changes when *aqua fortis* is poured on them; and this ought always to be made a part of the trial by the *Touch-Needles*, that no fraud may be at the bottom.

All gold rendered brittle, when compared with the *Touch-Needles* by the ſtone, will appear leſs pure than it really is; and on the contrary all ſilver rendered brittle, has the whiteneſs of ſilver in a higher degree: nor is there any wonder in this, when rightly conſidered, ſince the bodies which make gold and ſilver brittle are only a few metals, and ſemi-metals, all of a very bright white colour, and neceſſarily adding to the whiteneſs of ſilver, and taking from the yellowneſs of gold, ſuch are tin, lead, regulus of antimony, biſmuth, zink, and arſenic. Theſe dilute the yellow colour of gold or copper, into a whiteneſs, ſo that the colour of copper mixed with the ſilver is hidden by admixtures of this kind, whereas gold on the contrary appears by them to have much more ſilver in it than it really has.

In a white allay, *aqua fortis* does not diſcover the preſence of ſilver from twenty-three, to ſeven carracts, becauſe *aqua fortis* does not ſeparate ſilver from gold, unleſs the maſs contains three times more ſilver than gold.

Metallic ſtreaks or cruſts which have been left ſome time upon the *Touch-ſtone*, cannot be compared with freſh ones, with any degree of uſe, becauſe their remaining long on the ſtone always alters their colour.

Silver when tempered with braſs appears whiter than it would do with a like quantity of copper, and as it may then be rendered ſufficiently ductile by a proper operation, you will hardly be able to find out the fraud with the *Touch-ſtone*, unleſs you make a ſecond time the ſame compariſon with the ſtreak of a *Needle* of the ſame colour, having previouſly poured *aqua regia* upon the metallic cruſt laid by rubbing on the touch-ſtone; nor are *Touch-Needles* tempered with braſs, of any great uſe on this occaſion, ſince this artificial metal is ſometimes more and ſometimes leſs yellow.

Laſtly, if the metal laid upon the *Touch-ſtone* by rubbing does not appear neat or diſtinct enough, lick it over with ſpittle that is not frothy; and the colours will be by that means more diſtinctly and livelily reflected. *Cramer's* Art of Aſſaying, p. 116.

TOUCH-*Stone* (*Cycl.*) The *Iriſh* TOUCH-STONE, called *Baſanus Hibernicus*, by Molyneux and ſome others, is a black marble found in the county of Antrim in that kingdom, in angular columns, forming that amazing pile called by the vulgar, the giant's cauſeway.

This marble has the property of trying metals by the *Touch* beyond any other known ſtone; but it is not eaſily wrought into form, being ſo hard that it turns the edges of all the tools uſed to cut ſtones. Were it not for this it is admirably calculated for building, and for ornamental works; but nobody has attempted to uſe it in this manner, any where, except in the church of Ballywellan in the neighbourhood, and here the trouble of cutting is avoided, for the joints are taken as they found them, and the church is built of theſe in their natural ſhape, piled one upon another. The outer ſurface of this ſtone is of a whitiſh colour like lime-ſtone, but this is only the effect of the weather upon it; for where-ever it is broken it is found to be of a fine iron grey, and when poliſhed appears of a true and deep jetty black.

The accounts Pliny and others give of the *baſaltes* or *baſanus* found in Æthiopia and other places, agree extremely well in all reſpects with this Iriſh marble. They ſay it was always found in form of columns, and was much harder than the common marble, and of an iron colour: Kentman and other later writers, deſcribe alſo a pillared ſtone, found in Miſnia, the accounts of which agree perfectly well both with this and with the *baſaltes* of the antients: ſo that there is no great room to doubt but that both the Miſnian and the Iriſh columnar marble are the ſame with the *baſaltes* of the Greeks and Romans; and that this *baſaltes* is always found in the ſame columnar form, in whatever part of the world it is met with; and conſequently that the giant's cauſeway in Ireland, is no work of art as vulgarly thought, but only an immenſe congeries of this *baſanus* or *baſaltes* in its natural ſtate and form.

The columns of this marble are all regularly angular, but they conſiſt of a great number of ſides in ſome, and of a ſmall number in others. Some columns being octangular and others only triangular, and others of all the different numbers of angles between three and eight.

The Miſnian *baſaltes* is ſaid to have no columns of more than ſeven angles, or of leſs than four; by this account it appears that the Iriſh kind has two orders of columns which that wants, but this may be owing to want of due obſervation of the Miſnian kind: for Dr. Molyneux in his firſt account of this cauſeway, ſays, that its columns conſiſt of five angles at leaſt, or ſeven at moſt, but future obſervations alone can ſhew whether the Miſnian kind may not have other numbers of angles in ſome of its columns, from thoſe at firſt taken notice of, as well as this. Some of our Engliſh authors have been of opinion that the ſtone of the giant's cauſeway was of the *entrochus* or *aſteria* kind; but this is very abſurd, for the ſize of thoſe ſtones ſeems to be limited, as they are the remains of animals, and nothing

nothing of that kind can be larger than the part of the animal it had its origin from, whereas we can never suppose any animal so monstrously large to have at all existed, as that these columns should have been only a part of it.

The substance of this stone is also an unsurmountable difficulty against the opinion of its being of the nature of the *entrochi* and *asteriæ*, for they are all composed of spar, and are soft and crumbly; whereas this is too hard even for cutting in the common way of working other stones.

The columns of *basaltes* in Misnia, either are not jointed like those in Ireland, or the joints have not been observed; but supposing that they really are not jointed at all, they may nevertheless be the same stone, since the joints may have been obliterated by the stones coming together while yet soft, and subject to injury by pressure from above given by the succeeding addition of new joints: and, even in the Irish kind, the joints, tho' so very regularly formed in the way of ball and socket, in some are much less regular than in others, and, in some of the inland columns, are only two flat and smooth surfaces laid one upon another. It is not difficult to conceive that if these surfaces had met together in this close contact, while a little moist, they would have cohered together; so as to have left no mark of the joining.

Agricola describes a kind of marble found in the district of Hildesheim in Germany; which also agrees very well with our *basanus* of the giant's-causeway, and with the *basaltes* of the antients; and an author, who has wrote on the same subjects since his time, confirms his account: he says, that the marble is black, and in form of beams and columns standing up above the surface of the earth in the hills, and that being struck forcibly against with a bar of iron, it gives a strong smell like that of burnt horn. This agrees very well with the marble of the giant's causeway, which when put to the same trial has evidently the same effect. Philos. Transf. N°. 241.

TOURNEFORTIA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: The cup is a small *perianthium* divided into five segments, and remains after the flower is fallen; the segments are of a pointed figure. The flower consists of a single petal in form of an oval tube, longer than the calyx, divided into five slight segments, somewhat broad and pointed and spread open. The stamina are five tapering filaments of the length of the tube of the flower. The antheræ are simple and stand in the mouth of the flower. The germen of the pistil is globose, and situated under the cup. The style is simple and of the length of the stamina, and the stigma is simple. The fruit is a globose berry, containing two cells, the seeds are of an oval figure, two in number, and separated by the pulp. *Linnæi*, Genera plantarum, p. 62.

TOURNEQUET, in surgery, an instrument made of rollers and compresses with the help of a small stick, and used to stop the effusion of blood from large arteries in amputations by forcibly tying up the limb. The things necessary for this are a roller of a thumb's breadth, and of an ell in length, a small cylindrical stick, a conglomerated bandage two fingers thick and four long, some compresses of a good length, and about three or four fingers breadth, to surround the legs and arms, and a square piece of strong paper or leather about four fingers wide.

The manner of applying this instrument is this, the rolled bandage is to be applied to the trunk of the wounded artery length-ways, covering it in a contrary direction with compresses surrounding the leg, foot, or arm, as it were with a ring; the roller must be passed twice round these applications, and fastened in a knot, but so loosely that you may easily introduce your hand between it and the part: the leather or thick paper must now be nicely placed under it, upon the external part of the leg, and the roller tightened by degrees by turning round the stick, which is to be introduced into the knot; this to be done till the hæmorrhage is entirely stopped: the stick must now be kept in this situation till the wound is properly treated, and the return of the hæmorrhage prevented. When this end is acquired, the *Tournequet* is to be loosened, or entirely taken off, as shall be judged most convenient; but where it is applied to the arm, the rolled bandage is to be placed near the *axilla* in the internal part of the *humerus*, and the stick in this case is to be fastened on the opposite side, the situation of the artery there requiring this position; and when it is to be applied to the thighs, the bandage is to be put as the case shall require, either to the upper part of the thigh, or just over the knee. *Heister*'s Surgery, p. 47.

TOW (*Cycl.*)—Tow-*Chain*, in husbandry, a name given by our farmers to a chain, that makes a part of the structure of the plough, fastening the plough-tail to what they call the plough-head.

This is an iron chain of few links, and very strong; it is fixed at one end to a collar fastened to the middle of the beam of the plough, and at the other end passes thro' that part of the plough-head called the box, which is the timber thro' which the spindle of the two wheels run. The stake of the plough, which is an upright piece running parallel with the crow-staves, pins this in at the bottom, running thro' that link which comes out by the box; this stake is fastened by withs or cords in two places to the left crow-staffs, and the chain is thus kept firm. *Tull*'s Husbandry.

TOWER, in glass-making. See the article Leer.

TOXICODENDRON, *poison-wood*, in botany, the name of a genus of plants the characters of which are these. The flower is of the rosaceous kind, being composed of several leaves disposed in a circular form. The pistil arises from the cup, and finally becomes a fruit of a roundish shape, dry, not juicy, and usually of a striated structure.

The species of *Toxicodendron* enumerated by Mr. Tournefort are these: 1. The smooth trifoliate *Toxicodendron*. 2. The trifoliate *Toxicodendron*, with hoary sinuated leaves. *Tourn.* Inst. p. 610.

The most common American kind of this tree, is the ash-leaved one; it grows in marshy places, and is called by the common people marsh-sumach; its leaves resembling those of the common sumach, which are very well known to resemble ash-leaves in their pinnated structure. It grows to about four inches in diameter, and at the utmost does not exceed twenty feet in height. It spreads much at the root, and where one has been at any time cut down, there are always seen a great number of young ones growing from its stump. It is of very quick growth, but is not durable. The inside of the wood is yellow, and contains a juice which is as glutinous as turpentine; the wood itself has a very strong and disagreeable smell, but the juice stinks like carrion.

This tree poisons two ways; by handling of it, and by the smell. The scent of it when cut down in the woods has poisoned many people, and many more have suffered by it while burning in their fires. People with only handling it have been made blind for several days, and persons who sit near a fire when it is burning are often swelled and choaked up in all parts of the body in a terrible manner. It is very remarkable that the effect of this poison seems confined to some few persons, and that one may handle it ever so long, and even chew it without hurt, while another is poisoned by only touching it; and a whole company sitting by a fire where it is burning, shall often all escape except one or two, who will be swelled with it. The poison of this tree is never mortal, but goes off of itself in a few days; and the people who suffer by it generally carry its effects off the sooner, by using sallad oil and cream to the parts. The first notice the person has of being affected by it, is by feeling a violent itching in the skin; this provokes scratching and rubbing; and in consequence of this the part inflames and swells. Sometimes a person's whole body is swelled and poisoned in this manner, and sometimes only a particular part, as the legs; and, in this case, they often discharge a considerable quantity of water, and then grow well.

People who have been poisoned by handling it, affirm that it is so much colder to the touch than other wood, and that it may be distinguished by this in the dark; when it is burning some people are so affected by it as to swoon away, others yawn and seem uneasy, while the rest feel nothing of it. The fruit of this tree is a white roundish dry berry, growing in clusters. Philos. Transf. N°. 367. p. 144.

TOXICUS, in botany, a name by which some authors have called the *arundo farcta*, of which the walking-canes are made. *Chabræus*, p. 193.

TOXOTÆ, τοξόται, among the Athenians, bowmen, a sort of inferior officers, or rather servants, who attended the lexiarchi.

They were much like the Roman lictors: there were a thousand of them in the city of Athens, that lived in tents, erected first in the forum and afterwards in the areopagus. *Potter*, Archæol. Græc. T. 1. p. 79. See the article Lexiarchi.

TOZZIA, in botany, a name given by Micheli and continued by Linnæus to a genus of plants, the characters of which are these: The perianthium is very short; it consists of one leaf of a tubular figure, divided into five segments at the end, and remaining when the flower is fallen. The flower is one-leaved and open; the tube is cylindric, and longer than the cup. The extremity forms two lips; the upper lip is bifid and the lower trifid, and all the segments are nearly equal in size and of a roundish figure. The stamina are four filaments hid under the upper lip of the flower. The antheræ are roundish. The germen of the pistil is oval; the stile is capillary, of the length of the stamina; and the stigma is capitated. The fruit is a globose univalve capsule, having only one cell, in which is contained a single oval seed. *Linnæi* Gen. Pl. p. 302. *Michel.* p. 16.

TRACHEA (*Cycl.*)—Tracheæ, in vegetables, are certain air-vessels evident in many plants, but in none more beautifully or distinctly observable than in the melon.

Mr. Bulfinger observed that in cutting the root of the common melon transversely, there appeared, beside the bark and other commonly known parts of the root, a multitude of foramina, which were larger or smaller as the portions of the root were cut from a thicker or a thinner part. These are easily visible to the naked eye, for they are arranged into a number of fasciculi, which surround the axis of the root: there are usually three circles of these distinguishable in the smaller parts of the root, and four in the larger; and the matter in which they are

are placed is different from that which furrounds it, being much harder and more firm than that.

Moft of thefe fafciculi or foramina finally become divided into two or three portions, and the interftitial matter in that cafe is always the fame with that which furrounds them. If any number of thefe fafciculi are examined, the order and difpofition of the foramina, and even their numbers, are found the fame in all; they are fo regularly continued along the root, that air, and light fluids, may be fucked into the mouth thro' pieces of the root from two to nine inches long, and this even when they are contorted and crooked in their growth: the cafe is the fame alfo, whether the piece be cut from the root or from the ftalk of the plant, or from both; for when fuch a piece is cut, half of which is root and half ftalk, the continuation of thefe foramina is found to be the fame, and the air paffes, whether it be blown in at one end or the other: this is plainly feen on immerfing one end in water, and blowing in at the other, the bubbles of air arifing readily and in great quantities. Comment. Petropolit. Vol. 4. p. 182.

In the trunk or ftalk of the melon, there are always regularly twelve of thefe fafciculi with their regular foramina; and it is evident to the eye that thefe foramina are perfectly empty, if a fmall fegment of the root or ftalk be placed between the eye and a ftrong light. The number of fafciculi in the ftalk is the fame, whether it be cut near the root, or at ever fo great a diftance from it: the fame in the fmaller branches, and even in the pedicle which fuftains the fruit. The number of the cellules in the fruit alfo anfwers to that of thefe fafciculi in the ftalk, there being always the fame number when the fruit is perfectly and regularly formed, tho' fometimes from accidents there are only ten or eleven to be counted. In the pedicle of the fruit there are indeed more than twelve to be obferved, but thefe fupernumeraries are only ramifications of the orignal twelve; on the contrary in the pedicles of the leaves there are only nine of thefe fafciculi to be counted; five of thefe are placed on the convex fide of the ftalk, and are greatly ftronger than the others; and there are two middle-fized, and two others very fmall, in the other part. Thefe have their origin from the nine fafciculi of the ftalk which are neareft the pedicle; the other three run on without any divarication or without fending off any branches, and form the pedicle of the next leaf; fo that new leaves are produced by thofe alternate fafciculi. The three which run on uninterrupted, form the three great middle ribs of the leaf into which the pedicle expands, and the two lateral fmaller ribs are formed each of three other fafciculi taken in from the ftalk; and in fome of thefe the three fafciculi may be eafily difcerned on cutting them tranfverfely; in others only two fhew themfelves on examination; and fome part of one of thefe fafciculi may be always traced running out into every ramification of thefe ribs in the leaf, fo far as the beft glaffes are able to carry the fearch. Thefe fafciculi, as they are continued both thro' the ftalk and pedicles and even thro' the ribs of the leaves, carry the external appearance of a white ligneous fibre; and as they are protruded to great lengths and run into very flender ramifications, their foramina become lefs and lefs apparent, and at length efcape the obfervation with the very beft mifcrofcopes.

If at any time the ftalk near the infertion of a leaf, and the leaf itfelf near that part, has happened to rot; it is eafy to draw out thefe fafciculi regularly in the proper number; and thefe in their larger part fhew all their foramina very beautifully, while in the fmaller they become lefs and lefs diftinct. The main ftalk or trunk of the plant has a cavity or hollow in the middle, which is not continued to the root, nor to the pedicles of the leaves; and near the origin of the young branches, in that part of the ftalk to which the inner part of the leaf correfponds, there is a greenifh diaphragm which occupies the middle of the ftalk, into which the fibres of the ftalk, after making their ramification for forming the fafciculi of the pedicle, are inferted laterally; after which, penetrating the ftalk, and coming out at that part where the origin of the leaf is to be, they form a fort of thin membrane, which covers the tender firft fhoot of the leaf and the young branch. This membrane finally fhews its twelve fafciculi; and thus the true number is every where continued, unlefs in fome few places where two of them have happened to cohere on their running too clofe together; but in this cafe they foon divide again, and fhew their true number. Comment. Petropol. Vol. 4. p. 184.

From the whole it may be concluded, that if the *Tracheæ* of plants are continuous canals, containing only air, and compofed of a firm matter in their fides, thefe fafciculi before defcribed, as found in the root, ftalks, *&c.* of the melon, are true *Tracheæ*: for it is plain that they are empty canals, or containing no other matter than air; neither need it be doubted that there are fuch in all plants, becaufe in fome even the beft microfcopes cannot difcover them: for we find in this very plant that thofe *Tracheæ*, which in a part of their length are very confpicuous, become fmall and not to be diftinguifhed as hollow, in their finer and fmaller extremities; and in fuch plants as are fuppofed to have none of them, they may either be fo minute as not to have a difcernable hollow, or elfe their cavity, or at leaft the new made orifice of it, may be occluded by the other veffels of the plant throwing out their juices into it, on being wounded. We fee that in the melon thefe *Tracheæ* are carried from the root to every part of the plant with great regularity, and that they are included in what we commonly call the woody fibres of plants, and have their fides formed of the matter of thofe fibres; whether thefe fibres have any juices circulating thro' other fmaller canals, or are only deftined to fupport the *Tracheæ*, or air veffels, is a queftion not eafily determined: they are much dryer than any other fibres of the plant, and feem to contain no juices, except thofe deftined for their own proper nutrition. They have by fome been fuppofed to ferve for the carrying back to the root fuch juices as were not employed in the nourifhing the plant; but all experiments feem to difcountenance this conjecture, and it feems to have been built upon the obferving this part of the vegetable without feeing its true ufe, or finding out the numerous *Tracheæ* which it fuftained. The cavity in the middle of the ftalk may be attributed to the expanfion of the green fibres, and of the utriculi which form fo great a part of the plant; and the motion of the juices in thefe may poffibly be owing to the motion of the air in thefe *Tracheæ*, regularly dilating and contracting them. But the great eafe and plainnefs with which they are followed in this fearch is owing to their largenefs, and the tendernefs of the ftalk.

It is eafy to fee in what manner the ligneous parts of plants contribute to vegetation, fince in thofe parts only the *Tracheæ* are fituated: and hence alfo the reafon appears very obvious, why grafts do not fucceed unlefs the ligneous part of the ftock be touched in the operation; all the *Tracheæ* of the ftock being in this part, and it being impoffible that the *Tracheæ* of the graft fhould have any communication with them, unlefs brought into contact by opening this ligneous part of the tree. Act. Petropol. Vol. 4. p. 187.

Nothing fhews the *Tracheæ* of plants in fo beautiful a manner as a tranfverfe fegment of a young fhoot of the vine. They may be in this difcovered in a good light even by the naked eye; but with the help of but a fmall magnifying glafs they appear very beautiful and diftinct. In the generality of other trees, thefe *Tracheæ* are fo fmall, that even the largeft magnifiers in our microfcopes cannot well diftinguifh them: fo that Fontenelle and many other great men have doubted their exiftence: but even where thefe are fmalleft of all, as in the petiola or middle ribs of the leaves of plants, they may, tho' wholly imperceptible to the fight, be proved to exift, by experiments. If a fmall cylindric glafs be filled with water, and have all its air exhaufted from it by the air-pump, and the middle rib of a leaf be then cleared from the other parts, and cut off at both ends, and plunged at one end into this water; while yet in the exhaufted ftate, the bottom of the petiolum being fupported from touching the bottom of the glafs, the fituation and number of the *Tracheæ* in it will be eafily diftinguifhed by a ftring of bubbles, which, arifing from each of them, will make a row of beads, as it were rifing in a continued chain to the furface. Act. Erudit. Ann. 1722. p. 24.

TRACHELAGRA, a term ufed by fome medical writers to exprefs the gout in the neck.

TRACHELIUM, in Mr. Tournefort's fyftem of botany, the name of a diftinct genus of plants the characters of which are thefe: The flower confifts of one leaf, and is fhaped like a funnel, and divided into feveral fegments at the edge. The cup of the flower is finally converted into a membranaceous fruit, which is ufually of a trigonal form, and is divided into three cells, which ufually contain a number of very fmall feeds.

The fpecies of *Trachelium* enumerated by Mr. Tournefort are thefe: 1. The blue-flowered umbelliferous *Trachelium*. 2. The jagged-leaved violet-coloured umbelliferous *Trachelium*. 3. The hairy *Trachelium* with flowers growing in clufters from the alæ of the leaves. 4. The rock-*Trachelium* with flowers collected into heads. 5. The violet-coloured African *Trachelium*, with flowers growing fcatteredly all upon the ftalks. 6. The American fow-thiftle-leaved *Trachelium*, with very long white flowers. *Tournef.* Inft. p. 130.

TRACHELOMASTOIDÆUS, in anatomy, a name given by Albinus to a mufcle, called by Winflow and others the *complexus minor*, or *maftoidæus lateralis*.

TRACHELOS, a word ufed by fome anatomical authors to exprefs the neck.

TRACHIDNA, in ichthyology, a name given by Jovius and fome others to the *draco marinus* of the old authors, called by us the *weever*.

It is a fpecies of the *trachinus*, defcribed by Artedi under the name of the *trachinus* without beards and with the lower jaw longer than the upper. See the next article.

TRACHINUS, in the Linnæan fyftem of zoology, the name of a genus of fifhes, of the general order of the acanthopterygii: the characters of thefe are, that the opercula of the gills are pointed, and the eyes are placed near one another in the top of the head. *Linnæi* Syftema Naturæ, p. 53.

The characters of this genus, according to Artedi, are thefe: There is one or more prickles at the upper angle of the coverings of the gills, and the head has fome rough tubercles on

on it. The eyes are placed near one another in the upper part of the head. There are two back fins. The foremoſt one is very ſhort. The appendices of the pylorus are from eight to twelve in number.

The ſpecies of this genus are only two: 1. The *Trachinus* with the lower jaw longeſt, without beards. This is the fiſh called the *draco* and *araneus marinus*, and by us the *weever*. The other is the *Trachinus*, with ſeveral cirri in the lower jaw.

This is the uranoſcope, or *Trachinus* of authors, called alſo *callionymus*. *Artedi* Gen Piſc. See the article URANOSCOPE.

The name is originally Greek, the word τραχεινος ſignifying rough, ſharp, or prickly. It was given to this fiſh from the rays of its back-fin being remarkably rigid, and ſharp like prickles.

TRACHINUS *Lapis*, a ſtone mentioned by the writers of the middle ages, as poſſeſſing many great medicinal virtues. It ſeems to have been a kind of *lapis nephriticus*, being deſcribed as bright, but not tranſparent, and being of two kinds, the one blackiſh, the other green.

TRACHURUS, in zoology, the name of a fiſh of the cuculus-kind, called in Engliſh a *ſcad*, and by ſeveral authors, *ſuro*, *ſaurus*, and *lacertus marinus*.

It very much approaches to the nature of the common mackrel in colour, ſhape, and taſte; inſomuch that the French call it *maquereau-batard*, or baſtard-mackrel; but it never grows to the full ſize of the mackrel, and is of a more flat ſhape. Its back is of a very ſhining blue. Its belly white, with a faint bluſh of reddiſhneſs. Some have erroneouſly ſuppoſed, that it had no ſcales; but it is covered with conſiderably large ones. Its ſide-lines are one on each ſide, and are made each of a row of bony ſcales. Theſe have all eminences in their middle, and riſe ſo high near the tail, as to make that part of the body of the fiſh appear ſquare. The eyes are large, and the lower jaw is a little longer than the upper. The jaws are rough like files. The back has two fins, a ſhort anterior one, and a long one behind it; and the tail is conſiderably forked. This fiſh uſually ſwims in large ſhoals, and is caught in the Mediterranean, and on the Engliſh coaſts in Cornwall, and ſome other places. It is eſteemed a very well taſted fiſh. *Ray*'s Ichthyography, p. 290.

TRACHURUS *Braſilienſis*, a name given by Mr. Ray to a fiſh of the cuculus-kind, commonly eaten in the Braſils, and known among writers on theſe ſubjects by its Braſilian name *guaratereba*. *Ray*'s Ichthyology, p. 291. See the article GUARATEREBA.

TRACING, in huſbandry, a term uſed by our planters for the method of preſerving the maize, or Indian corn. This, being a large grain, is apt to ſpoil, if not carefully preſerved.

Some thraſh out the corn as ſoon as the ears are gathered, and lay it up in holes of the earth, which are their granaries: But thoſe who have not opportunities of doing this, *trace* it, that is, they leave it in the ear, and weave, or faſten together a great number of ears by the ends of the huſks: Theſe *traces* of corn they hang up within doors, on ſuch ſupports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own, of burying the clean corn, was at leaſt as good, and was the ſame practiſed by the Ægyptians of old, and by all the wiſeſt nations of the eaſt at this time. But whether we have improved their huſbandry in this particular, or not, it is certain that we have greatly aſſiſted them in the planting this corn, which we do by the plough, inſtead of the troubleſome method they had of doing it with the hoe. The manner of our planting it is this: We plough ſingle furrows the whole length of the field, and at about ſix foot diſtance one from another; we then plough others acroſs at the ſame diſtance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by running another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plough the ſpaces again, and by this means deſtroy and turn in all the weeds, and give the earth ſtirring, that greatly aſſiſts vegetation.

The famous method of horſe-hoing huſbandry, ſo celebrated by Mr. Tull in a book written on that ſubject, is no other than a bringing home this method of our American planters, in the culture of the maize, and applying it to our European corn, with which, however it can never ſucceed ſo well. The Indians, and our planters, join in the method of raiſing a hill of earth round every ſtalk of the maize; and when the ground is poor, or out of heart, they bury two or three fiſhes, of a kind called by them the *aloofe*, under every hill, and by this means they have a crop double to what would otherwiſe have been produced. The Engliſh have learned this manure from the Indians; and in New England, where they are near the fiſhing-ſtages, they bury the heads and garbage of the cods, which ſucceed as well as the aloofe, and coſt nothing but the carriage.

The lands on which the maiz or Indian corn has grown, are as well fitted for our European corn as if they had been laid fallow. The reaſon of this is, that the plants of the Indian corn ſtanding at ſix feet diſtance from each other, the far greater part of the ground has remained unoccupied, and at the ſame time has had the advantage of often ploughing to kill the weeds, which is a benefit equal to that of dung and reſt. All this, though it tends to prove the doctrine of horſe-hoeing huſbandry not new, yet it ſtrengthens the ſyſtem greatly.

The Indians, who do not intend an after-crop of European corn, occupy all the ground which they have been at the pains of clearing for the maiz, in another manner: They plant with the corn, in the ſame hill, a kind of kidney bean; this grows up with the corn, and its ſtalks climb up about thoſe of the maiz, which ſerve as well as ſticks or poles for it. In the center, at every vacant place between the hills, they plant ſquaſhes or pompions, which ſucceed very well; and often, after the laſt weeding of the ground, they ſprinkle in a quantity of turnep-ſeed; ſo that when the harveſt is over, they have a crop of turneps for the winter. Phil. Tranſ. N°. 142.

TRACING, among miners. See the article TRAINING.

TRACTORIÆ, among the Romans, were diplomas or tickets given by the emperor to ſuch as he ſent into or called out of the provinces, whereby they were entitled to the uſe of the public poſt, and to be maintained at the expence of the government. *Pitiſc.* in voc.

TRAGACANTH, or *Goat's-Thorn*, *Tragacantha*, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, finally becomes a bicapſular fruit, containing ſeveral kidney-ſhaped ſeeds: To this it is to be added, that the leaves ſtand in pairs upon the ribs, which uſually terminate in a prickly point.

The ſpecies of *Tragacanth*, enumerated by Mr. Tournefort, are theſe: 1. The common *Tragacanth*. 2. The woolly *Tragacanth*, ſuppoſed to be the *poterium* of Cluſius. 3. The purple-flowered ever-green Alpine *Tragacanth*. *Tourn.* Inſt. p. 417.

TRAGACANTHUM *venereum Indicum*, in natural hiſtory, a name given by ſome writers to the birds neſts ſo famous in ſoops in China, and in ſome parts of Europe, for their cordial reſtorative, and provocative virtues. They are the neſts of a kind of Indian ſea-ſwallow, and are made up of a ſubſtance reſembling gum-tragacanth, and, like it, melting in a jelly in any warm and watery liquor.

TRAGASIAN *Salt*, a term uſed among the antients for a ſort of ſea-ſalt, very little different from the common kind, being made by the evaporation of the water of ſome ſalt ponds near the ſea-ſhores.

TRAGELAPHUS, in zoology, the name of an animal of the goat-kind, of which there are two ſpecies, the one deſcribed by Geſner, the other by Bellonius.

The *Tragelaphus* of Geſner is a little larger than our common deer; its colour the ſame with that of this creature, and its hair of the ſame ſort and length; but its body is thicker; and its legs much ſhorter. Under its chin it has the beard of the goat; and all the way along the under part of its throat there runs a ſeries of long hairs, which hang down almoſt to its knees; the upper part of its neck has a mane of long hairs alſo, which are much darker-coloured than thoſe of the body. Its knees are covered alſo with long and thick tufts of hair, reaching a good way backwards. Its hoofs fall off every year. The horns reſemble thoſe of the ram, or rather of the goat, and are black, and bent backwards. The ears are ſhort. The eyes, the tail, and the parts of generation, are the ſame as in deer. It is a very gentle animal, and full of ſport and play, and is found wild among the rocks.

The *Tragelaphus* of Bellonius, is a creature with the hair of the goat, but without its beard; its horns do not fall of, and are of the ſhape of thoſe of the goat, but not unfrequently curled like thoſe of the ram. Its head, face, and ears, are very like thoſe of the ram; and its ſcrotum is very large, and hangs down in the ſame manner with that creature's. Its legs are of the length of the ram's; its hips under the tail are white; its tail black; and its neck, both on the upper and under part, and its breaſt alſo, are ſo hairy, with long hairs, that they look as if covered with one continued beard. The hairs on the ſhoulders and breaſt are long and black; it has on each ſide a remarkable grey ſpot; its noſtrils are black, and its mouth and the under part of its body white. *Ray*'s Syn. Quad. p. 82.

TRAGIA, in botany, the name of a genus of plants, the characters of which are theſe: It produces male and female flowers on the ſame plant. In the male the perianthium is divided into three ſegments, which are ovated, acute, and expanded. There are no petals. The ſtamina are three capillary filaments, of the length of the cup; and the antheræ are roundiſh. Plumier makes this cup a monopetalous funnel-faſhioned flower; but this does not appear to be really the caſe. In the female flowers the cup is divided into five ſegments, which are ovated and hollow. The germen of the piſtil is roundiſh, and furrowed with three lines. The ſtyle is ſingle, erect, and longer than the cup. The ſtigma is trifid and expanded. The fruit is a very large tricoccous capſule, of a roundiſh figure. The ſeeds are ſingle and roundiſh. *Linnæi* Gen. Plant. p. 448. *Plumier*, Gen. 12.

TRAGIC *Dance*, in antiquity. See the article EMMELIA.

TRAGICUS *Musculus*, in anatomy, a name given by Albinus to one of the muscles of the eye, called by Santorini and Winslow, *Musculus Tragi.*

TRAGIUM, in botany, a name by which some authors have called the fraxinella, or bastard-dittany, the root of which is used in medicine. *Ger.* Emac. Ind. 2.

TRAGIUM *Germanicum*, in botany, a name given by some authors to the *atriplex olida*, or stinking orach. *Ger.* Emac. Ind. 2.

TRAGO-ORIGANUM, in botany, a name given by some authors to the *marum Syriacum*, or Syrian herb mastic. *Pluk.* Alm. p. 374.

TRAGOPOGON, *Goats-beard*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the semiflosculàr kind, being composed of a number of semi-flosculès placed on the embryo-seeds, and contained in a cup divided into many segments; but not of the scaly kind. The embryos finally ripen into seeds, which are enveloped in a sort of covering, and winged with down, and are all fixed to the thalamus of the flower. See Tab. 1. of Botany, Class 13.

The species of *Goats-beard*, enumerated by Mr. Tournefort, are these: 1. The great yellow-flowered meadow-*Tragopogon.* 2. The lesser yellow-flowered meadow-*Tragopogon.* 3. The *Tragopogon*, with long sinuated leaves. 4. The *Tragopogon*, with leek-like leaves, and pale violet-coloured flowers. 5. The leek-leaved *Tragopogon*, with bluish purple flowers, commonly known by the name of *artis.* 6. The leek-leaved *Tragopogon*, with blackish-purple flowers. 7. The leek-leaved *Tragopogon*, with blue flowers. 8. The leek-leaved *Tragopogon*, with white flowers. 9. The grassy-leaved *Tragopogon*, with bright red flowers. 10. The crocus-leaved *Tragopogon*, with bluish purple flowers. 11. The yellowish purple small *Tragopogon.* 12. The hairy *Tragopogon.* *Tourn.* Inst. p. 477.

There are two or three species of this plant well known among us, the one wild in our meadows and pastures, by the name of *go to bed at noon*, from its flowers always shutting up in the middle of the day; another kept in our gardens for its beautiful red flowers; and a third cultivated for its esculent root, and known by the name of salsafy. This was originally from Italy, and is still kept in many gardens as a good root; but is not common in our markets.

These plants are propagated by sowing their seeds in spring on an open spot of ground. The salsafy should be sowed in rows at nine or ten inches distance; and when the plants are come up, they should be left at about six inches asunder in the rows; they then require no farther care but to be kept clear from weeds; and if the soil be light, and not too dry, they will grow to a considerable size by winter. The roots are to be taken up for use when the leaves are decayed, and continue in season till March; and then the young shoots, which are very large and thick, are by many boiled as asparagus, and make a very delicate dish. *Miller's* Gardeners Dict. in voc.

TRAGOSELINUM, in botany, the name of a genus of umbelliferous plants, the characters of which are these: The flower is rosaceous, consisting of several heart-shaped leaves, irregular in size, and disposed in a circular form, and standing on a cup which afterwards becomes a fruit, composed of two oblong seeds, which are gibbose and striated on one side, and flat on the other.

The species of *Tragoselinum*, enumerated by Mr. Tournefort, are these: 1. The great *Tragoselinum*, or pimpernel-saxifrage, with white flowers. 2. The great *Tragoselinum*, or pimpernel-saxifrage, with red flowers. 3. The great *Tragoselium*, or pimpernel-saxifrage, with burnet-leaves. 4. The lesser *Tragoselinum*, or common small pimpernel-saxifrage. 5. The tall African *Tragoselinum*, called by authors the great African pimpernel-saxifrage.

TRAGULA, among the Romans, a strong kind of javelin, with a barbed head. *Pitisc.*

TRAGUM, in ichthyology, the name given by Aristotle, and others of the old Greek writers, to the *trugum* of Elian, Athenæns, and Oppian. Both names are used to express the fish called by authors the *pastinacha marina*, and by us the *fire-flaw*, or *fire-flaire.* The fish is a species of the raja, and is distinguished by Artedi by the name of the smooth-bodied ray, with no fin on the tail, and with a long spine placed on it, serrated before. See the articles RAJA and PASTINACHA.

TRAINING, or TRACING, (*Cycl.*) in mineralogy, a term used by our miners to express the tracing up the mineral appearances on the surface of the earth to their head or original place, and there finding a mine of the metal they contain.

The principle on which this practice depends, is the change wrought in the face of the earth by the deluge, of the effects of which these remains are a very great proof. The superficial, or upper part of veins, or loads of ore, is always the poorest, the richer ores lying deeper down, the poor ones only serving to lead the way. These poor ores, or stones impregnated with the metalline matter of the mine, and called by our workmen, *shoad-stones*, were, probably, at the creation of the earth, brought regularly up to the surface, and shewed the places of the metals below. But at the time of the covering the earth by the waters of the deluge, they were, with the rest of the surface, washed off, and carried, with the descent of the water, down into the plains, or into the beds of rivers, and there carried many miles down the stream. This being an allowed truth, the art of *Training* a mine is easy; for though this carrying the shoad-stones and poor ore, was done so many ages ago, yet all the way that some pieces were carried on, others would be deposited by the way, and the heaviest and richest falling first, the lightest would always be carried farthest, and there would be always left a stream of this matter all the way from the place where it was first produced, that is, where the mine now is; for the breaking of the surface of the earth, at this great catastrophe, was not so deep as to reach that; and this stream or *train* of matter will be found richer and richer as it approaches the mine, and finally will stop at the place where it is.

Where there is supposed to be a mine of any metal, the hills and country all about are diligently searched; the situations, and descent of the lands, and the earth, stones, and other fossile bodies, are examined, particularly the colour and nature of the various sorts of earths and stones which are found on the hills where the mine is suspected to lie, that they may be readily known again if any of them are found in the neighbouring valleys. The stones which denote the loads, and are called *shoad-stones*, are found two, three, four, or even five miles from the hills, where they originally lay; but if the same sort of stones are remembered on the hills, the *Train* is to be made out.

After any great land-flood, in which it is supposed there are usually some new frets made in the banks of the rivers, these are carefully examined, to see whether any metalline stones may be found in their sides and bottoms, all being then so clean, that the smallest shoad-stone may usually be seen. If no stones of this kind are found, it sometimes is of use, in order to farther researches, to examine whether any pieces of earth, of a different colour and nature from that of the rest of the bank be found; for this being, if any such is found, washed also from the neighbouring hills, it proves a great direction which side of the hill to search into.

If no shoad-stone or grewt of a different nature from the rest be found in these frets or newly worn banks, the miners leave the place for the present. For though the bed of the river afford many metalline stones, they never regard them, the continual change of place they receive from the current of the water rendering them only tokens that there is metal somewhere in the country; but they confound and perplex rather than instruct in the search after the places where it is.

If there be found indeed stones of the shoad-kind, full of protuberances, or having sharp angles, as if newly broken, it may be worth while to see whether they are not washed out of some part of the neighbouring banks by the late floods; as this sort of appearance is a token of their having been newly taken into the bed of the river. But if they are rounded and smooth, it may be concluded that they have been long subject to the action of the water, and brought, perhaps, many miles from the places where they were originally lodged in the earth, and where only they could have been of any use to the *Tracer* of the mine.

When the frets in the sides of rivers have been traced in vain, the searcher after a mine goes up to the sides of the hills most suspected to have mines in them, and there seeks for a convenience of bringing a little stream of water to run down. When this is found, he cuts a trench about two foot over, and as deep as the shelf. The water is turned into this cut, and after two or three days running in it, all the filth will be washed away, and the looser part of the earth cleared off; and if any shoad-stones are lodged within the whole course of this cut, they will be found. If any such are found, it is an unquestionable proof that there is ore in the higher parts of the hill; this encourages the work, and there is always found a mine, or at least a squat, which will, without much danger, repay the expence and trouble. The squats are flat parcels of the ore, lying in different and distinct places of the hills, and not communicating with one another.

Sometimes a great deal of this labour is saved, and the shoad-stones are found on the surface of the ground, either turned up by the plough, or thrown up in small quantities in mole-hills, or raised by some other accident; for they are seldom found naturally lying on the very surface of the earth; for the putrid remains of vegetable and animal substances, and other adventitious matter, has raised the surface of the earth in all places, since the time of the flood, and made indeed a sort of new surface. These stones were certainly laid bare on the surface of the ground, at the time of their being carried down from the mines; but this adventitious matter has buried them in this long tract of time, and they are generally found under about a foot of a sort of vegetable mould. If, by any of these searches, a shoad is found, the miners have nothing to do but to follow it to its head, and there make the opening; but if no such direction can be had, nor any shoad found, and there is yet suspicion that there is a mine in the hill, the method is to make an *essay-hatch*, as it is called; this is sunk near the

foot or bottom of the hill, and is an opening of about fix foot long, and four foot broad, made in the fearch of a vein as deep as the fhelf; this is a caution that muft be always carefully obferved, for if they are made lefs deep than this, they may mifs of the vein tho' there is one. And the finking thus deep is always attended with certainty, for if no fhoad is found on this, it may be concluded there is none there; except that fometimes it is found that the fhoad has been wafhed clean away, within two or three foot from the land: and then the load or vein is two foot farther or thereabouts up in the hill. If any fhoad is found in the effay-hatch, there is a certainty of a vein of ore; neither doth it add a little toward the making a conjecture how high up the hill, or how far off the vein ftring, or bonny is, carefully to mark how deep from the furface of the earth the fhoad lies, for this is held an infallible rule, that the nearer the fhoad lies to the fhelf or faft ground, the nearer the vein itfelf is, and *vice verfa.*

When there is no fhoad or appearance of a mine found in the firft effay-hatch, if the conjecture of a mine being in the hill has any tolerable foundation, the *tracing* it does not end here; but they go ten or twelve fathom up the hill and there open a fecond effay-hatch, and if no ore or fhoad-ftone is found in this, they go as many fathom on each hand at the fame height with the fecond hatch; and there open a third and a fourth hatch, of the fame depth and dimenfions with the firft; if in neither of thefe there is found any fhoad-ftone, they afcend proportionably with three more hatches, if the fpace of ground require, at every ten or twelve fathom, and in this manner open them three abreaft, at twelve fathom diftance up to the top of the hill. If no fhoad is found in any of thefe, it is concluded then that there is no *tracing* a mine there, and the hill is left.

If any fhoad is found in any of thefe hatches or openings, the afcending hatches from this are kept on in a direct line, and the deeper the fhoad lies the nearer the vein is. The fhoad grows gradually deeper from the furface, but nigher the fhelf as they approach the mine; as fuppofe it be but half a foot from the fhelf and feven foot deep from the furface, the vein is then concluded to be within a fathom or two; and on this the firft proportion of twelve fathom between every hatch is leffened, to fix, four, two, one, or even lefs than that, as the vein is conjectured to be more and more near.

It often happens, for want of a good guefs in this matter, that the diggers over-fhoot the load; that is, they open their next hatch too high up the hill, or above the load or vein: this is a miftake eafily difcovered and eafily rectified. If a fhoad is found lying near the fhelf in one hatch, and in the hatch above there is no fhoad at all, it is a proof that the hatch is too high, and the remedy is only to fink a hatch at a middle diftance between the laft two, which will probably fall upon the very point of the load, and finifh the work of *tracing*.

Sometimes it happens, that in continuing the *tracing* of the firft fhoad, a fecond or new one is found; it is not uncommon for two fhoads to be thus found in one hatch, and this is eafily difcovered without any danger of miftake; for fuppofe in the laft hatch the fhoad which they *trace* lay at eight foot deep, and in this it lies at ten foot, and befide this there is a fhoad found at two foot depth; it is very certain that the fhoad at ten foot deep is the fame they were before *tracing*, and this is a new one pointing to another vein or load, which is now firft difcovered fo near the furface of the earth. This has generally gravel or earth mixed with it, and is to be carefully examined; when the higher hatches are opened, this is continually found as well as the old load; and when the firft is *traced* to the point of the vein, this fecond is to be continued in the fame manner, by other hatches opened at the fame diftances above: it often happens that in *tracing* this fecond fhoad, the hatches dug for it difcover another new one or a third fhoad; all thefe are to be *traced* one over the other by the fame hatches, and will all be found worth the feeking after. The old writers on mineralogy agree with us in this obfervation, and tell us, it is not uncommon in fome places to find as far as feven loads lying parallel to one another in the fame hill. In thefe cafes, however there is ufually one mafter-load, or grand vein; the other fix, that is three on each fide, being the leffer or concomitant veins. Five in the fame manner, fometimes lie in this order, the grand load in the middle and two on each fide, but the more common method is three, a large one, and two fmaller.

Every load has a peculiar coloured earth or grewt about it, which is found alfo with the fhoad, and this always in a greater quantity the nearer the fhoad lies to the load, and becomes leffened by degrees to the diftance of about a quarter of a mile, further than which that peculiar grewt is never found in any quantity with the fhoad; fo that this is a proof that the load or vein is near when it is found in quantity.

A valley may chance to lie at the foot of three feveral hills, in fuch a manner, as to contain three feveral grewts, or that earth which was moved with the fhoad in the concuffion of the ftrata at the deluge, with as many different fhoads or *Trains* of fhoad-ftones in the midft of each: in this cafe it will be very neceffary to know the caft of the country, and of each hill in refpect to its grewt, for the furer *training* of them one after another as they lie in order: according to the foregoing rules of effay-hatching, the uppermoft in this cafe always directs which hill to begin with firft.

It fometimes happens, that after having *trained* the fhoad found in a valley up to the upper parts of a hill, there is only a fquatt, or bonny found inftead of a right vein of ore, for thefe detached parcels of ore have their fhoads as well as the right veins. Thefe are ufually about two or three fathom long, and a fathom broad; few of them are larger, moft lefs, and they never communicate with any other load or vein, nor ever fend forth any of their own. The extremities of thefe beds of ore terminate without fending out any ftrings, not lying within walls as the loads; but tho' they are in the fhelf or faft ground, not moved by the flood, their furface is equal every where with that of the imaginary fhelfy one, and they go down five or fix fathoms deep and there terminate at once. The ore contained in thefe are rich, and they are always wrought out to the confiderable advantage of the owners.

Thefe are the general rules of *tracing* mines, and tho' fomewhat tedious and expenfive, they are certain, and never liable to the error and difappointment the other fhorter ways, as they are called, are liable to. Thefe fhort ways are by the *virgula divinatoria* or the hazel-wand, whofe bending in certain places without any external vifible force, is to point out the place where the vein of ore lies: the waters thought to iffue from the particular loads are alfo ufed by fome as a fhort means of finding the veins; other of thefe ways are alfo by mineral fteams and effluvia, by the barrennefs of the foil, and the pitching of nocturnal lights on the fuppofed orifices of mines. But thefe methods are too extravagant or too uncertain to be ufed in cafes of fo much confequence. When the mine is found by the more certain rules of *tracing*, the digging it is a matter of lefs difficulty. Phil. Tranf. N°. 69. See the article DIGGING.

TRAMELLED, in the manege. A horfe is faid to be *tramelled*, that has blazes or white marks upon the fore and hind foot of one fide; as the far foot before and behind. He is fo called from the refemblance the white foot bears to a half *tramel*.

Crofs-TRAMELLED *Horfe*, is one that has white marks in two of his feet that ftand crofs-ways, like St. Andrews crofs; as in the far-fore-foot, and the near hind foot, or in the near foot before, and the far-foot behind.

TRAMMELS, a kind of net ufed in fowling, the defcription of which fee under the article LARK.

TRAMIS, a word ufed by fome medical writers, to exprefs the line running along the middle of the *fcrotum*, from the *penis* to the *anus*.

TRANCHEFILE, in the manege, the crofs chain of a bridle that runs along the bit-mouth, from one branch to the other.

TRANSCENDENTAL (*Cycl.*)—TRANSCENDENTAL *Cofmology*. See the article COSMOLOGY.

TRANSFORMATION (*Cycl.*)—TRANSFORMATION *of Infects*. It is well known that flies are not produced in that form, from the eggs of their parent fly, but undergo a change like that of the butterfly, and the like winged infects; the egg hatching into a worm; and this after eating, and performing all the operations of animal life for a certain time, enters into a ftate of reft, and thence is changed into a fly.

Though the general courfe of nature is the fame in this refpect in flies and butterflies, yet the means and manner of it are different; the butterfly makes its coat for this *Transformation*; the fly-worms of many kinds have only a fhell of their own proper fkin to undergo this change in.

All the fly-worms of the firft and fecond, and many of thofe of the third clafs, have their cafe thus made only of their own fkin; the different fpecies afford indeed fome varieties in the manner of this, but a general idea of the work may be had from obferving the worm or maggot of the common flefh-fly in its feveral ftages.

When this creature has arrived at its full growth, it finds it not convenient any longer to remain among the food it has till then lived upon; it quits it and now goes in fearch of a place where it may wait for its metamorphofis. To this purpofe it creeps into the earth, where it remains two or three days without any change; at the end of this time, inftead of its pointed figure, its white colour, and foft flefhy fubftance, it acquires the figure of an egg, and becomes of a chefnut colour, or fomewhat redifh, and looks opake and cruftaceous; it is in this ftate perfectly ftiff, and deftitute of motion, and the creature feems not only to have loft its form, but wholly to have loft its life alfo. *Reaumur's* Hift. Inf. Vol. 4. p. 288.

This however is not the cafe, all that is done, is that the creature has abfolutely quitted its fkin, which is now become hard and of a determinate figure, and is within it compleating all its changes. Ibid. p. 289.

The manner in which this change of figure is given to the fkin, is by the creature's drawing its head, and the two or three firft rings of its body, within the reft, and by that means making itfelf of this fhape, fhort and equally thick at each end. It does this within a few hours after it creeps into the earth, and if taken out after that time is always found of this fhape, and feems to be *transformed*, only that its fkin has not yet acquired

quired its brown colour. This however is not at all the cafe, for it can now walk as before, and thrufting out its head and the rings it had drawn in, can again acquire its former figure, which however it lofes afterwards at once, and becomes rigid in a few minutes, and in two or three hours the fkin it has quitted, and which is now a fhell, becomes reddifh, and after a little more time acquires its proper chefnut colour. Ibid. p. 290.

This coat is now no more a fkin, but a fhell, and fit to perform all the offices of one; it is no longer connected to the body of the animal, but is become hard, brittle, and rigid. It may however yet be diftinguifhed, efpecially by the help of the microfcope, to be made up of a great number of rings, which may be more diftinctly counted than they could be in the worm: there are nine of thefe between the caps, which make the two ends; two rings at leaft, without counting the head, go to the forming the anterior cap, which is purfed or wrinkled up like the top of a bag when clofely drawn together; but thefe folds or wrinkles do not abfolutely meet and clofe up the end. The microfcope fhews at each extremity of one of the diameters of this cap two little bodies not at all diftinguifhable by the naked eye; each of thefe is one of the anterior ftigmata.

On the two rings which follow this cap immediately, underneath each of thefe ftigmata; there may be obferved a fmall band, very little elevated above the furface of the reft of the fhell. Thefe feem the two ftrongeft parts of the fhell, but they are in reality on the contrary the two weakeft, and are the places where the fhell is to fplit and open to give paffage to the fly. Ibid. p. 293.

On the cap which makes the other extremity of the fhell may be feen, the two pofterior ftigmata, thefe are the moft confiderable in the creature, and are each a collection of three oblong ftigmata. Ibid. p. 294.

The *Transformation* in this fhell is double, before the infect becomes what it is to be finally, a fly like its parent; the firft *Transformation* is into an oblong mafs of matter, void of all form, either of the worm it was, or of the fly it is to be; but from this it by degrees affumes the figure of the nymph, in which all the lineaments of the future fly are diftinguifhable. This *Transformation* (which is in thefe, and perhaps in all the worms that make a cafe of their own fkin, prior to their change into the nymph ftate) may be called the change into the long ball or fpheroide, or into the ellipfoide. This fly-worm of the blue fly is one of thofe, which with moft difficulty fhews this *Transformation*; but on boiling it at a proper time and afterwards carefully opening the fhell, it will always be found in this ftate. Ibid. p. 295, 296.

It is a very eafy thing to be provided with thefe worms in their fhell ftate, in a fufficient quantity; and it is a very pleafing examination to boil and open feveral of them daily, to fee the progrefs in their refpective *Transformations*; by this means after two or three days one may diftinguifh the legs on the anterior part of the body, but very fhort; the day following, the wings will begin to fhew themfelves, and the ends of the legs will be found extended toward the hinder part; a day afterwards the end of the trunk may be diftinguifhed, and the head begins to fhew itfelf. And finally the legs will be feen in their due length and proportion, and the reticular eyes will very plainly fhew themfelves. Ibid. p. 299.

Several accidents, as the heat or cold, and drynefs and wetnefs of the feafon, contribute much to the forwarding or backwarding thefe fucceffive changes: in fummer the worms will remain fometimes in a moift earth fix or feven days without changing; and others will acquire their fhell-ftate in a dry earth in two or three days: a moift earth may alfo very eafily much impede the fecond *Transformation*, from the ftate of the oblong ball into the nymph. Since in order to this there is required an evaporation of a great deal of moifture, which is in the fhell; and this cannot be fuppofed to be fo readily performed in a moift as in a dry place; and that fuch an evaporation is required is very plain, from the change of weight in the fhell in thefe two ftates; for when the contained animal is in the form of its oblong ball, the fhell is in the whole heavy enough to fink in water; but when it has acquired the form of the nymph, it is fo light that it fwims. Ibid. p. 305.

The time required for thefe feveral changes often differs a little, and fometimes confiderably; but at a medium it ftands thus: the worms which have been feen to creep into the earth on the 21ft of April, have come out perfect flies on the 16th of May, and that in a cold feafon for the time of the year.

The fhells of feveral of this brood opened on the 28th and 29th of April, fhewed the infect in form of the oblong ball; the parts of the nymph were not difcoverable in any opened before the 30th of April; but thefe fhewed the legs of a third part of the length of the body: thefe nymphs had all a cavity on their anterior part; but thofe opened on the 2d and 3d of May had not this cavity; but the dart and hooks vifible in it before were now applied againft the furface of the cap, and the head of the future fly fhewed itfelf: on the fourth of May the trunk appeared very fair, and the reticular eyes were become vifible, tho' all that was now vifible, was feen thro' a thin and delicate fkin. Ibid. p. 306.

On the 6th of May the *antennæ* were diftinguifhable, and their form very perfectly finifhed; on the 7th the fmooth fmaller eyes were diftinguifhable. The 8th of May the reticular eyes had acquired a reddifh colour; the 9th the colour was yet more natural; the 10th thefe were become of a deep red, and the fmooth eyes looked reddifh; and on fome of the ftigmata of the nymph, the fpots of the former worm were now eafily difcoverable; on the 11th the nymphs were all become hairy; on the 12th thefe hairs were more vifible, and of their natural colour, and the legs were become greyifh, and of their full length. The lips of the trunk were of their natural colour, almoft black; and the antennæ began to be coloured; and the whole fhape of the fly was very diftinct. The 13th, 14th, and 15th days made no great changes, as the parts were now already formed, and only wanted their proper ftrength and confiftence; and on the laft day, before their egrefs, and not before, did they appear to have any power of motion; which, as foon as they had it, was applied to the freeing themfelves from their fhell, and coming out in the form of the parent fly. Ibid. p. 308.

The changes a multitude of other fly-worms undergo, and their fhells made of their proper fkin, are the fame in all effential points with thofe of the flies firft mentioned. Some fpecies have their fhell more deeply annular, others almoft entirely fmooth; fome have the two ends fomewhat pointed, and others only one of them fo; and in fome this larger inflated end is the anterior, and in others the pofterior. Ibid. p. 309.

Swammerdam, to whom the world is indebted for the firft true infight into the wonders of the infect world, has evidently proved, that what had before been called by the pompous and myfterious names of changes and *Transformations* of one animal into another, as of a worm into a fly, and the like, is, in reality, no more than a gradual and natural growth and evolution of the parts, not any metamorphofis of them; and this growth refembles very well, when judicioufly confidered, not only the increafe of other animals, but alfo the natural budding and increafe of plants.

The progrefs of thefe changes, as they are called, in infects, is expreffed by two different terms in their two moft remarkable ftates; the words are the *nymphæ* and the *chryfalis*.

Thefe words are often mifunderftood, and even mifapplied and confounded by authors one with another. What the moft accurate authors have originally meant by them, however, is this:

The nympha is the change of the worm, which carries the proper fhape of the future little animal; and the chryfalis, or aurelia (for thefe words have the fame fenfe, derivation and meaning) the change of that caterpillar, which fhews no parts at all of the animal that is to come.

This is the regular meaning of the two words; but Swammerdam proves them to exprefs, as the fchoolmen call it, diftinction without difference, for that he was always able to difcover the feveral parts of the future animal, as well in the chryfalis as in the nympha; and that others had only made the difference from the want of due attention and application.

This author therefore makes no other difference between the nympha and chryfalis, but this; that fince the parts of the future animal are not fo plainly difcernable in the chryfalis as in the nympha, and a fine golden colour is very common in the more obfcure ftate of the animal, and is not found on any of thofe fo perfect, as to be vulgarly called nymph; it may be proper to exprefs, by certain forms of fpeech, thofe flight but obvious differences; but not to give them the pompous names of *Transformations*, and the like. The nymphs he therefore calls fimply puppets, and the chryfalis's by the name of gilt puppets.

Swammerdam refers the general changes, as they are called, of the infect tribe, into four claffes, one or other of which takes in that of every known infect, a very few excepted, whofe progreffions have not yet been fufficiently inquired into, to afcertain their nature. The four general claffes, or ranks of changes, are diftinguifhed by four different ways of production, change, and growth.

The firft rank, which he expreffes by the name of nymph-animal, hath a little animal fully formed in the egg, which, after the evaporation of the fuperfluous moifture, comes forth perfect, and fo grows up. Such is the loufe, and the like.

The fecond clafs are diftinguifhed by the name of *nympha-vermiculus*. Thefe have the parts of the future infect imperfectly fhaped in the egg, and, after hatching, leave the creature to acquire its perfection vifibly by outward food. Of this kind are the grafshopper, the locuft, the cricket, and many other the like creatures.

The third clafs he diftinguifhes by the name of *nympha-chryfalis*, or *nympha-aurelia*. Thefe, after hatching, obtain their perfection darkly, and not till after the cafting off the laft fkin; fuch are the butterfly and the like. The fecond and third clafs agree in this, that not a perfect animal, but a worm is produced from the egg, and precedes the growing of the perfect parts; yet with this difference, that in the fecond the little creature grows up manifeftly and obvioufly to the eye; but in the third all is in darknefs and obfcurity under the fkin, and, as it were, within the body of the creature.

The fourth clafs is diftinguifhed by the phrafe *nympha vermiformis*; and the creatures of this clafs remain always fhut up in the cafe of the worm or maggot, without any poffibility of difcerning the parts, till cafting both fkins at once, it becomes a perfect and free animal, capable of propagating its fpecies.

Thofe infects which come forth perfect, and in their own proper form, out of the egg, fuffer no future changes, but only the cafting off their fkins; but thofe which come forth under the envelopement of a vermicular coat, do, befide cafting their fkins, after a proper time of eating and crawling about in that ftate, become nymphæ; and that all infects, as well thofe which come out of the egg in the worm ftate, as thofe which come forth in their own form, are originally, in the egg, all in the nymph-form; and that thofe which come out of the egg perfect animals, have no other difference in the manner of their productions, from the others, but that they have fuffered in the egg, and out of the way of our infpection, all thofe changes which the others do undergo in the chryfalis or nymph-ftate, in our fight. The parts of the nymphæ of thefe animals protuberate and expand themfelves by degrees, much in the fame manner that the buds of flowers of plants do; and the caterpillar is certainly the butterfly itfelf, only covered with a mantle which hides its feveral limbs from our eyes till thrown off.

Thus are the general tribes of infects regularly reduced to thefe four claffes, in regard to the manner of their production. Thofe particular fpecies which feem not reducible to thefe, or any other rules, or for which farther obfervation at leaft is required, are the glow-worm, the fcolopendra, the julus, the weavil or curculio, the dung-beetle or pilularius fcarabæus, the fmalleft water-beetle, and the fcorpion. See thefe under their feveral heads. *Swam.* Hift. Infects.

TRANSFUGA, in antiquity, a deferter. Among the Romans, deferters were commonly punifhed by cutting off their hands, it being thought, that living in fuch a miferable truncated condition, would ftrike more terror than death itfelf.

We find, however, that deferters were likewife crucified, burnt alive, thrown from the Tarpeian rock, or expofed to wild beafts at public fhews. *Pitifc.* in voc.

TRANSMUTATION (*Cycl.*)—Transmutation *of Metals*. Among the many things urged in favour of the belief of the poffibility of this effect of chemiftry, the experiment of Thurneiffer, who, in the prefence of the Great Duke of Tufcany, converted one half of a common iron nail into gold, by only dipping it, while hot, into a certain liquor, has given great encouragement to the fearchers after that famous fecret. The nail is ftill preferved in the repofitory of the Great Duke of Tufcany at Florence; and we have, in a very famous Englifh collection, the blade of a knife, half iron and half gold, faid to have been effected in the fame manner, and purchafed by the prefent poffeffor at a very confiderable price.

Tachenius, however, has difcovered the cheat of the Florentine nail; and probably the matter does not ftand much better, on examination, with the Englifh knife. This author gives a procefs by which iron may be fo prepared as to be made to mix perfectly with gold. This was the whole fecret of Thurneiffer, who in this manner made his nail half iron and half gold, and then coating it all over with a ferrugineous matter, made it appear all iron. When this had been, in this ftate, fubjected to the examination of the prince, and a great many other perfons, he heated it red hot, and by that means burnt off the ferrugineous part of the golden end; and then dipping it into a certain oil, which he pretended to have great efficacy, the gold appeared, and was pretended to have been made by the oil from the iron. *Tachenii* Hippocrat. Chem.

Mr. Boyle thinks there is no impoffibility in the nature of the thing, that one metal fhould be *tranfmuted* into another: And in confirmation of this opinion, he mentions a *tranfmutation* of gold into filver, by means of his *menftruum peracutum*. Monfieur Homberg declares, he has changed filver into gold by heat [a]. Mr. Boyle alfo mentions an anti-elixir, which, in very fmall proportion, would confiderably debafe gold [b] in many refpects, and particularly by reducing its fpecific quantity from 19 to $15\frac{2}{3}$ times that of water.—[[a] Mem. Acad. Scienc. Anno 1709. [b] Works abr. vol. 1. p. 78.]

Transmutation *of Colours*. The change of colour of a decoction of the nephritic wood, according to the different lights it was viewed in, long perplexed the wits of thofe who attempted to account for it; but Wolfius has carried the experiments on this decoction much further, and found a way of giving it its colours again, after taking them wholly away. If this decoction be held between the eye and the light, it appears of a blue colour; but if the eye be placed between it and the light, it appears then of a yellowifh or a reddifh colour. If a few drops of oil of vitriol be dropped into it, it will appear of a gold yellow in whatever light it is viewed; but if too much of this oil be added, the whole becomes foul and obfcure; and if a few drops do not produce the effect, it is a fign that the decoction is too ftrong, and that it muft be diluted with water.

Oil of vitriol has the fame effect upon many other decoctions of the woods, particularly on that of Brafil wood, which is of a fine red, but immediately becomes yellow on dropping a fmall quantity of this acid into it. And, as in the other inftance, fo in this, it is neceffary to the fuccefs of the experiment, that the tincture be not over ftrong. A few drops of oil of tartar added to this yellow liquor turn it red again, as at firft; and if more oil of tartar be added, the colour becomes bluifh, with a tinge of red, much ftronger than the colour of the nephritic wood at firft, when held between the eye and the light. In all experiments of this kind, the weaknefs of the tincture produces the greateft beauty; and therefore it is beft, inftead of making a decoction, to make only a cold infufion, by putting a fmall quantity of the chips of the wood into water, and letting this ftand cold for fome time. Act. Erudit. Ann. 1718. p. 321.

A tincture of red rofes, made with common water and oil of vitriol, is well known to be of a very beautiful red colour; yet when the water has ftood ever fo long on the rofes alone, it has fcarce any colour: If it be ftrained off in this colourlefs ftate, and the oil of vitriol then added, the red colour is produced as ftrongly as if this acid had been dropped into the water while the rofes were yet in it. When the liquor is of this fine red colour, a fmall quantity of oil of tartar makes it immediately green; and if more oil of vitriol be added to this green liquor, it becomes red again, but is muddy, and not fo well coloured as before. If a few drops of a folution of corrofive fublimate be added to this, it does not at all change colour; and on adding more water, with falt of tartar diffolved in it, the liquor became red again, but of a very different red from what it was before in its muddy ftate, being now clear and deeper. When the tincture of rofes has fcarce any colour, a fmall quantity of falt of tartar makes it green, but a large quantity makes it yellow. A few drops of oil of vitriol added to this yellow liquor, turned it to a pale red, and this could never be made green again by oil of tartar. Alum-water, added to a folution of falt of tartar, makes a white and opake fluid, though they are both feparately pellucid.

What is moft obfervable in thefe experiments on the infufion of woods, is, that oil of tartar, and a folution of falt of tartar in water, have a very different effect. Thus an infufion of Brafil wood is red; and on dropping to it a few drops of oil of vitriol, it becomes yellow. If oil of tartar be added to this liquor, it only makes it yet more yellow; but if a folution of falt of tartar in water be added to this, it makes it red again. Act. Erudit. Ann. 1718. p. 322.

TRANSPIRATION (*Cycl.*)—Transpiration *of Plants*. It is evident that plants as well as animals continually fuffer a lofs of their fubftance and juices, and that in two manners; by a fenfible *Tranfpiration*, and by an infenfible one. The latter of thefe is perceived very plainly in obferving, that in the heat of fummer, toward the clofe of the day, thofe plants which in the morning were very lively and vigorous, and in a perfectly good ftate, are then found feeble, and, as it were, withering, and bending down toward the earth. It is with thefe plants juft as it is with men and other animals, who are in the fame manner faint and languid, by reafon of their great *Tranfpiration* during the heat of the day.

The fenfible *Tranfpiration* of plants is lefs eafily proved than this infenfible one, which feems fomewhat ftrange. By fenfible *Tranfpiration* in a plant we underftand an evacuation made by means of the pores of the leaves of a fubftance too thick and coarfe to be evaporated as foon as difcharged, as the matter of the infenfible *Tranfpiration* is. This matter is, however, not unfrequently found on the leaves of trees, though it is there ufually miftaken for the remains of dew fallen upon them.

This, however, is not the cafe, as may be eafily determined by the following confiderations: 1. That the fluid matter upon the leaves of thefe trees is not merely aqueous, but is vifcid and glutinous, and fweet to the tafte. 2. That it is always found in greater quantity on thofe leaves which are expofed to the fun, than on thofe which are fhaded. 3. The leaves which abound in this appear lucid and gloffy in feveral places, thefe lucid parts fometimes appearing only in form of fpots, and fometimes in fmall fpaces of a twelfth of an inch long; and fometimes leaves are found with their whole upper furface covered with one continued coat of it. 4. There is no appearance of this matter upon the leaves, either in the night, or before fun-rife in the morning; the occafion of which is, that it is only drawn out by the heat of the fun; and being in itfelf of the nature of manna, that is, being foluble in aqueous menftruums, it is carried off and diffolved by the dews which fall in that time. 5. The bees are often found collecting this matter from the leaves of trees, as carefully, and loading themfelves with it in the fame manner, in order to make honey, as they do the fweet fubftances from the bafes of flowers. This matter is the fame with that in flowers, both are extravafated in the fame manner, and both are collected by the bee without injury to the plant. Since honey, therefore, is the matter of the fenfible *Tranfpiration* of plants, it cannot be wonderful that it fhould fometimes have the flavour of that plant whofe juices it once was a part of, or that the Narbonne honey fhould have the flavour of rofemary; and fo of others.

The trees which yield this fenfible *Tranfpiration* in the moft obvious manner, are the feveral fpecies of maple and of lime. It is found more or lefs on a vaft number of others; and many plants,

plants and all flowers abound with it, almoft without exception. It is in thefe moft obvious in the bottoms of the monopetalous kinds, fuch as the jafmine and the meadow-trefoil; on fucking of which there is always a great deal of it evident to the tafte. The leaves of any of the trees which afford this fenfible matter of *Tranfpiration* being put into water renders it purgative, and in all things analogous to a folution of manna; but, in general, more agreeably tafted. Mem. Acad. Par. 1707.

TRANSPORTATION (*Cycl.*) — TRANSPORTATION *of Plants.* In the fending plants from one country to another, great cautions are neceffary. The plants fent from a hotter country to a colder fhould be always put on board in the fpring of the year, that the heat of the feafon may be advancing as they approach the colder climates; and, on the contrary, thofe which are fent from a colder country to a hotter fhould be fent in the beginning of winter.

The beft way of packing up plants for a voyage, if they be fuch as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as clofe together as may be; the plants fhould be fet in thefe boxes three weeks before they are to be put on board, and in good weather they fhould be fet upon the deck, and in bad removed or covered with a tarpaulin.

If they are going from a hotter country to a colder one, they muft have very little moifture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being fhaded from the heat of the fun, they will come fafe.

Very many plants, however, will live out of the earth a great while; as the fedums, euphorbiums, ficoides, and other fucculent ones. Thefe need no other care than the packing them up with mofs in a clofe box; and there fhould be a little hay put between them, to prevent them from wounding or bruifing one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come fafe from a voyage of two, or three, or even four or five months.

Several trees alfo will come fafely in the fame manner, taking them up at a feafon when they have done growing, and packing them up with mofs. Of this fort are oranges, olives, capers, jafmines, and pomegranate-trees. Thefe, and many others, are annually brought over thus from Italy; and though they are three or four months in the paffage, feldom mifcarry. And the beft way of fending over feeds, is in their natural hufks, in a bag, or packed up in a gourd-fhell, keeping them dry, and out of the way of vermin. *Miller*'s Gardeners Dict.

TRANSTRUM, in the naval architecture of the antients, a term ufed to exprefs a fort of crofs or tranfverfe feats that were placed in the polycrote gallies of thofe times, and ferved for the places of feveral of the rows of men, who could move and work their oars under the feats of the other or lateral rowers of the next tire.

Meibom, who has written exprefly on the naval architecture of the antients, has better underftood the places and ufe of thefe *Tranftra*, than any other author of late times; by a proper arrangement of thefe feats, and the lateral ones above and below each, he has taken off greatly from the height allowed by Scaliger, and others, to the polycrote veffels. *Meibom.* de Trirem.

TRANSVERSALES *Abdominis* (*Cycl.*) — Thefe are mufcles nearly of the fame breadth with the oblique; they take their name from the direction of their fibres, and each of them is fixed to the ribs above, to the os ilium, and ligamentum Fallopii below; and to the linea alba before, and behind to the vertebræ.

Its upper part is fixed to the lower part of the cartilaginous furface of the two loweft true ribs, and of all the five falfe ribs, by flefhy digitations; the fibres of which become tendinous, as they approach the linea alba. The middle part is fixed to the three firft vertebræ of the loins, by a double aponeurofis or two tendinous planes. The internal and external planes having inclofed in their duplicature the mufculus facrolumbaris, and quadratus luborum, unite in one ftrong aponeurofis at the edges of thofe mufcles. The inferior part of this mufcle is fixed by an infertion wholly flefhy to the internal labium of the crifta of the os ilium, and a great part of the ligamentum Fallopii. *Winflow*'s Anat. p. 168.

TRANSVERSALIS *Anticus primus Capitis*, a fmall, pretty thick, and wholly flefhy mufcle, about the breadth of a finger, fituated between the bafis of the *os occipitis* and the tranfverfe apophyfis of the firft vertebra.

It is fixed by one end in the anterior part of that apophyfis, and from thence turning up a little obliquely. It is inferted by the other end in a particular impreffion between the condyle of the *os occipitis* and the maftoide apophyfis of the fame fide behind the apophyfis ftyloides, and under the edge of the jugular foffula. *Winflow*'s Anat. p. 238.

TRANSVERSALIS *Anticus Capitis fecundus*, a fmall mufcle, fituated between the tranfverfe apophyfis of the two firft vertebræ of the neck. It is fixed by one extremity very near the middle of the fecond apophyfis, and by the other near the root or bafis of the firft.

TRANSVERSALIS *Colli major*, a long thin mufcle, placed along all the tranfverfe apophyfis of the neck, and the four, five, or fix under apophyfes of the back between the complexus major and minor, and lying as it were on the infertions of the firft of thefe mufcles.

It is compofed of feveral fmall mufcular fafciculi, which run directly from one or more tranfverfe apophyfes, and are inferted fometimes in the apophyfis neareft to them, fometimes in others more remote, the feveral fafciculi croffing each other between the infertions of the two complexi, which are likewife croffed by them. *Winflow*'s Anat. p. 243.

TRANSVERSALES *Colli minores*, very fmall and fhort mufcles, found in the interftices of feveral tranfverfe apophyfes in which they are inferted, and called by fome alfo *inter-tranfverfales*. *Winflow*'s Anat. p. 244.

TRANSVERSALIS *gracilis Colli*, a long thick mufcle, refembling the *Tranfverfalis* major in every thing but fize, and fituated on the fide of that mufcle.

It is commonly taken for a portion or continuation of the facrolumbaris. Diemerbroek diftinguifhed it by the name of *cervicalis defcendens*; and Stone, and others after him, have called it *acceffiorius mufculi facrolumbaris*. *Winflow*'s Anat. p. 243.

TRANSVERSALES *Dorfi minores.* Some particular mufcles of this kind are found fixed to the extremities of the three loweft tranfverfe apophyfes of the back: The reft are all in fome meafure continuations of the *Tranfverfalis major*; but thefe few which are diftinct, and lie in the interftices between the apophyfes and diftinct mufcles, are properly enough called by this name. *Winflow*'s Anat. p. 248.

TRANSVERSALIS *Digitorum Pedis*, a fmall mufcle which lies tranfverfely under the bafis of the firft phalanges, and which at firft fight appears to be a fimple mufcular body, fixed by one end to the great toe, and by the other end to the little toe. When carefully examined, it is found to be fixed by a very fhort common tendon to the outfide of the bafis of the firft phalanx of the great toe, conjointly with the antithenar, and by three digitations to the interoffeous ligaments which connect the heads of the four metatarfal bones next the great toe. The three digitations are very flender, and gradually cover each other. *Winflow*'s Anat. p. 225.

TRANSVERSALIS *Penis*, in anatomy, a name given by fome writers, particularly Cowper, to a mufcle called by others *virgæ lateralis parvus*, and by Albinus the *Tranfverfus perinæi*. Winflow calls it *Tranfverfus urethræ*.

TRANSVERSO-SPINALIS *Lumborum*, called by fome *facer*, a mufcle compofed of feveral oblique converging or tranfverfofpinal mufcles, in the fame manner as in the back and neck.

It lies between the fpinal and oblique apophyfes of the loins reaching to the os facrum. The loweft of thefe mufcles are fixed to the fuperior lateral parts of the os facrum, to the ligamentum facro-fciaticum, and to the pofterior fuperior fpine of the os ilium. The reft are fixed to the three loweft tranfverfe apophyfes, and to the four loweft oblique apophyfes of the loins, and to their lateral tuberofities; from thence they run up to all the fpinal apophyfes of thefe vertebræ. The external, or thofe that appear firft, being longer than the internal, efpecially toward the lower part. *Winflow*'s Anat. p. 248.

TRANSVERSUS *Auriculæ*, in anatomy, a name given by Albinus to a mufcle of the ear, not allowed to be fuch by other authors; but defcribed by Santorini, and others, under the name of *fibræ tranfverfæ in gibbo auriculæ*, and *fibræ in convexa conchæ parte.* See the article EAR.

TRANSVERSUS *Nafi*, in anatomy, a name given by Santorini, and others, to that mufcle of the nofe called by Winflow *Tranfverfalis five inferior*; and by Albinus, the *compreffor naris.* See the article COMPRESSOR.

TRANSUM, in gunnery, is a piece of wood which goes acrofs the cheeks of a gun-carriage, or of a gun to keep them fixed together; each *Tranfum* in a carriage is ftrengthened by a bolt of iron. See the article CARRIAGE.

TRAPA, in the Linnæan fyftem of botany, a genus of plants; the diftinguifhing characters of which are thefe: The cup is a perianthium compofed of one leaf, divided into four at the edges, and remaining when the flower is fallen. The flower is compofed of four petals larger than the fegments of the cup, and placed vertically. The ftamina are four filaments of the length of the cup; the antheræ are fimple. The germen of the piftillum is of an oval figure; the ftyle is fimple, and of the length of the cup; and the ftigma is headed, and has a ridge round it. The fruit is an oval oblong ftony capfule, containing only one cell, and armed with four thorns placed oppofitely on the fides; thefe are thick and pointed, and are what were originally the leaves or fegments of the cup. The feed is a nut of an oval figure. *Linnæi* Gen. Plant. p. 50.

TRAPEZIUM, in geometry, a plain figure contained under four unequal right lines.

TRAPEZIUM *Os*, in anatomy, is one of the bones of the carpus; it is the firft bone of the fecond row, and has its name from its figure, which is a fort of unequal fquare. Its outer furface is rough, and makes a part of the outer or convex furface of the carpus. On its inner furface is an oblong eminence, which makes one of the four eminences on the concave fide of the carpus; and on the fame fide it has a

groove or channel; there is likewise a small tubercle on its outer surface.

This bone has several articular cartilaginous sides, *viz.* one brachial, one digital, and two cubital. The brachial side, which is hollow, is articulated with the os scaphoides; the digital with the first phalanx of the thumb; one of the cubital with the os trapezoides, and the other with the first bone of the metacarpus. The side which is articulated with the first phalanx of the thumb, appears to be made up of two superficial sigmoide or semilunar half-sides, distinguished by an eminence of the same figure, being each more hollow towards the sides than at the middle, which makes a portion of a sort of superficial pulley, with the edges much worn. One of the cubital sides, which is articulated with the os trapezoides, is large; and the other, which joins the first metacarpal bone, is small. *Winslow's* Anat. p. 83.

TRAPEZIUS (*Cycl.*)—This muscle is a large, broad, thin, fleshy plane, situated between the occiput and back, and thence extending to the shoulder, in figure of a large irregular square, and, together with the *Trapezius* of the other side, it forms a kind of lozenge. Above it is fixed in the superior transverse line of the os occipitis, by a thin series of fleshy fibres reaching to the musculus occipitalis, and seeming to cover that muscle by a kind of aponeurosis. Behind it is fixed to the five superior spinal apophyses of the neck, by means of the posterior cervical ligament, and immediately to the extremities of the two lowest spinal apophyses of the neck, and of all those of the back. From all these insertions the fibres run in different directions, and terminate by one continued insertion in about one third part of the clavicula, in the posterior edge of the acromium, and through the whole superior labium of the spine of the scapula, all the way to the small triangular surface in that spine, over which surface the fibres slide and pass freely, without being fixed therein. This muscle covers immediately the splenius or mastoideus superior, part of the complexus major, the angularis, rhomboides, and part of the latissimus dorsi. The common insertion of the two trapezii in the cervical ligament, is the reason that in pulling either of them toward one side of the neck, the other will follow it a little beyond the spinal apophyses. *Winslow's* Anatomy, p. 173.

TRAPEZOID, in geometry, a plane irregular figure, having four sides, no two of which are parallel to each other.

TRAPEZOIDES *Os*, in anatomy, is the second bone of the second row in the carpus. It has its name from its figure supposed to approach that of an unequal square; but it might much more properly have been called os pyramidale, being in figure rather a kind of a pyramid, with its point broken off. Its basis makes a portion of the outer or convex side of the carpus, and its truncated point a part of the concave side.

It has several articular sides; one brachial, which is the least of all, and is articulated with the os scaphoides; one digital, of a considerable length, notched on each side, and divided into two halves by a sort of middle line or angle, which gives it the appearance of a pulley, articulated with the basis of the first metacarpal bone; one radial, irregularly triangular, and articulated with the os trapezium; and one cubical, a little hollow, and articulated with the os magnum. *Winslow's* Anat. p. 84.

TRAPEZUNTINA *Laurus*, a name used by some botanical authors, for the *Laurocerasus*, or common laurel. *Chabræus*, p. 51.

TRAPPINGS. Among the antients some will have the horse *Trappings* to have been placed on their breasts; others, on their forehead; and others again, on their cheeks. That on the breast was a small kind of shield, finely polished. *Hofm.* Lex. univ. in voc.

TRAQUENADE, in the manege. See the article ENTREPAS.

TRASCINA, in zoology, a name by which some authors have called the fish, more usually known by the name of the draco marinus, and araneus. *Salvian* de Aquatic.

TRAVAIL, in the manege. See the article TRAVICE.

TRAVELLING. The common method of *travelling* in England being on horseback, it may be proper to give some general rules for the keeping the creature sound, and doing the business agreeably, and without many of the accidents which usually attend it.

Care must be taken that the shoes be not too streight, and do not pinch the horse's feet any way; but be well shaped, and set easy. It is proper to have them put on fresh a few days before the journey, that they may last well, and that they may be settled to the feet before the setting out. The bridle is next to be examined; that the bit of it be proper, and not too heavy: for if it be, it will incline him to carry low when he grows tired, and rest upon the rider's hand: This is what they call the using a fifth leg. It is a very disagreeable thing, but may often be avoided, only by taking a proper care of the bit. The mouth of the bit should rest upon his bars, about a finger's breadth from his tushes, so as not to make his lips uneasy. The curb should rest in the hollow of his head, a little above the chin; and if it gall him, the place must be defended with a piece of buff or other sort of leather.

The next thing to be regarded, is the saddle; and proper care must be taken as to this, that it do not rest either upon the withers, reins, or back-bone; and that one part of it do not press upon the back, any more than another. Some riders gall a horse's sides below the saddle with their stirrup leathers: This is most likely to happen to a lean horse; and to prevent it, a leather strap should be fixed between the points of the fore and hinder bows of the saddle, and the stirrup-leathers should be made to pass over these leathers.

It is always best to begin a long journey by short stages, and this is the more necessary if the horse has not been exercised for some time before. If it be a horse that is rid, he should be suffered to stale as often as he likes, and even invited to it; but, if a mare, she is to be less indulged in it as less necessary, and often diminishing her Strength. It is always advisable to ride very softly for a quarter of an hour, or half an hour before coming in to the inn at night, that he may not be over hot when put into the stable; but if the haste of the journey will not admit of this, the horse should be walked in some person's hands, to cool him gently before he is put up.

If the weather is cold a cloth should be laid over him while he is walked; and when taken in, his whole body should be rubbed and dried with straw. Some have a custom of ordering their horses legs to be rubbed well down, on their first coming in; but this is very prejudicial while the horse is hot, and should always be let alone till he is perfectly cooled.

As soon as the horse is cooled, and ceases to heat in the flanks, the bridle is to be taken off, the bit washed, and hay given him that he may eat at pleasure. The dust in very dry weather will sometimes clog up the tongue of the horse in such a manner, that he cannot eat without great difficulty; In this case some bran and water should be first given him to wash his mouth, or the servant should do it with a wetted spunge.

These are the proper methods, when the horse has been rode moderately; but when he has been hurried at a great rate, the saddle is to be taken off as soon as he is put up, and the sweat rubbed off with a sweat knife; and then the whole body and legs are to be rubbed carefully down, and the head is to be wiped with a cloth, as also the back under the saddle, and the thighs; then the saddle should be clapped on again, and the horse gently led up and down, till cool and dry. The feet are also to be examined, to see if a shoe be wanting, or if any of them press upon the sole; and the dirt, gravel, or other foulness is to be picked out from between the shoe and the foot. The openings of the feet may be stopped with cow-dung, and the hoofs if brittle should be anointed with some fatty substance just at the setting on; and in dry weather they should be greased, not only at night, but noon. Many horses, as soon as unbridled, will lay themselves down, instead of eating.

Many are apt on this to suppose the horse sick; but it is generally owing only to the heat and pain they find in their feet, which renders them unable to stand upon them: In this case if their eyes are examined, they will be found brisk and good, and the hay being offered them as they lie, they will eat it greedily. This shews there is no inward disorder, and the heat and tenderness of the feet, if examined, will shew that they are the part in pain. The principal thing to be done in this case, is taking care that the shoes do not rest upon the soles. This is not easily known but by taking off the shoes, which in cases of extremity should always be done; it will then be found where the sole is touched by the shoe, being in that part more smooth and shining than elsewhere. In this case the feet are to be pared in those parts, and then the shoes are to be fixed on again, anointing the hoofs, and stopping the soles with hot black pitch or tar.

These are the means by which *Travelling* will be rendered easy and commodius both to the rider and the horse; but there is some care also to be taken of the creature, after he comes off from a long journey. The first thing to be done is, that the two heel nails of the fore-feet are to be drawn, and if the shoe be large, then four should be drawn; two or three days after the horse should be blooded, and for ten or twelve days after this he should be fed with wet bran, without any oats; but he is to be kept well littered. The reason of drawing the heel nails is, that the feet are apt to swell after journies; and if this is not done the shoes press upon them in that part, and become very uneasy to them; it is adviseable to stop them also with cow-dung for some time; but they are in the wrong who pare them down after taking off the shoes, for the humours being all in motion after this, they are apt to fall into the feet.

If there appear any danger of the creature's legs swelling after the journey, it may be easily prevented by this means: Take a quantity of the dung of an ox or cow fresh made, mix it with so much vinegar as will reduce it to a soft paste, and add to it a handful of salt; with this rub all the hips thoroughly up to the knees, and let it dry on; give the water in a pail that evening that the legs may not be wetted, and the next morning the horse is to be led to water, and the whole remaining matter washed off. The jockies have a very cunning trick to recover the hoofs of a horse injured by a long journey:

journey: They make a hole in the foot, and fill it with moiftened cow-dung; they keep this in it a month, and the continual moifture occafioned by it makes the hoof grow very quick, and foon recover the proper dimenfions, but it foon after drys and fhrinks fo, that the foot is ftreightned, and the whole hoof becomes brittle.

Cow-dung applied to a horfe's foot always moiftens the fole; but it drys up the hoof, if continued any length of time to it. The beft method of recovering a horfe's hoofs is to make a hole in the ftable floor filled with blue clay a little wetted, in this the horfe fhould keep his fore-feet a month; this will have more effect then a fmall portion of cow-dung in the foot; and the effect will be of fo different a nature, that the hoof will be rendered more tough than before, inftead of being made brittle by it.

Moft horfes that are fatigued, or overworked by long journies, have their flanks altered by it, without being purfy; efpecially horfes naturally vigorous, which have been worked too violently. The beft remedy in this cafe, is to give the horfe half a pound of honey in the morning, mixed among a feed of fcalded bran: If he eats the half pound readily, give him a pound the next morning; continue this till the honey ceafes to purge the creature; after this, powder of liquorice may be added to the fcalded bran, and this continued fome time, and two or three glyfters at convenient diftances of time will be found very ferviceable. If the horfe be very lean, it will be proper to give him fome wet bran over and above his proportion of oats; and grafs is alfo very proper, if the creature be not inclined to be purfy. This caution, however, is to be had at all times, that exceffive feeding may be bad, by fubjecting the horfe to the farcy. When the horfe begins to drink heartily, it is a fign that he will foon recover. Though this fometimes fails, it is a good general rule.

TRAVERSE (*Cycl.*)—TRAVERSE, in the manege. A horfe is faid to *traverfe*, when he cuts his tread crofs-wife; throwing his croupe to one fide, and his head to another.

TRAVERSE-*Board*, in a fhip, a little round board hanging up in the fteerage, and bored full of holes upon lines fhewing the points of the compafs: Upon it by moving of a little peg from hole to hole, the fteerfman keeps an account how many glaffes, that is, half hours, the fhip fteers upon any point.

TRAVERSE-*Table*, in navigation, is the fame with the table of difference of latitude and departure; being only the difference of latitude and departure ready calculated to every degree, point, half-point and quarter-point of the quadrant; and for any diftance under 100 miles, though it may conveniently ferve for more.

This table is one of the moft neceffary things a navigator has occafion for; for by it he can readily reduce all his courfes and diftances, run in the fpace of twenty-four hours, into one courfe and diftance; whence the latitude he is in, and his departure from the meridian may be found.

TRAVERSE *the Yard*, on board a fhip, is to brace it aft.

TRAVICE, in the manege, is a fmall enclofure, or oblong quadrangle placed before a farrier's fhop, and confifting of four pillars or pofts, kept clofe together by crofs-poles. This enclofure is defigned for holding and keeping in a horfe that is apt to be unruly or diforderly in the time of fhoeing, or of any operation.

This in fome of the remoter parts of England goes by the name of a *break*; and is called in French *Travail*.

TREACLE (*Cycl.*)—Dr. Shaw, in his Effay on Diftillery, has endeavoured to bring into ufe feveral forts of *Treacles*, which might be made at home, and would ferve very conveniently for the diftillation of fpirits, or the making of potable liquors.

Thefe are the infpiffated juices or decoctions of vegetables: Such as the fweet juice of the birch, or fycamore, procured by tapping or piercing the trees in fpring, and the common wort made from malt, or from other vegetable fubftances treated in the fame manner. Thefe liquors are feverally to be boiled down in a copper till they begin to infpiffate, and then to be poured into a balneum mariæ, when the remainder of the evaporation may be finifhed without burning the infpiffated juices: Thus prepared it may be at any time reduced to the ftate of wort, only by adding a fufficient quantity of warm water. *Shaw*'s Eff. on Diftill.

TREAD, in the manege. See the article PISTE.

TREASURER (*Cycl.*)—TREASURER *of the County*, he that keeps the county ftock.

There are two of them in each county, chofen by the major part of the juftices of the peace, &c. at Eafter feffions.

They muft have 10 *l.* a year in land, or 150 *l.* in perfonal eftate, and fhall not continue in their office above a year; and they are to account yearly at Eafter feffions, or within ten days after, to their fucceffors, under penalties.

The county ftock, of which this officer hath the keeping, is raifed by rating every parifh yearly; and is difpofed of to charitable ufes, for the relief of maimed foldiers and mariners, prifoners in the county gaols, paying the falaries of governors of houfes of correction, and relieving poor almshoufes, &c. And the duty of thefe *Treafurers*, with the manner of raifing the ftock, and how it fhall be difpofed of, is fet forth particularly in the ftatutes of 43 Eliz. c. 7. Jac. I. c. 4. 11 & 12 W. III. c. 18. 5 Ann. c. 32. 6 Geo. I. c. 23.

TREASURER, in cathedral churches, an officer whofe charge was to take charge of the veftments, plate, jewels, relicks, and other treafure belonging to the faid churches. At the time of the reformation, the office was extinguifhed as needlefs in moft cathedral churches; but it is ftill remaining in thofe of Salifbury, London, &c.

TREASURY (*Cycl.*)—The Athenian *Treafury* was facred to Jupiter Σωτὴρ, or the faviour, and to Plutus the god of riches. Befides other public monies, there were always a thoufand talents kept in it, which it was capital to touch, unlefs on the moft preffing occafions. See the article OPISTHODOMUS.

The funds among the Athenians which fupplied their *Treafury*, were four, *viz.* the *tele*, τελη; the *phori*, φοροι; the *eifphoræ*, εισφοραι; and the *timemata*, τιμηματα. Each of which fee in its place.

The public *Treafury* was divided into three parts, according to the ufe it was applied to; as, 1. The χρηματα τῆς διοικήσεως, or that expended in civil ufes. 2. The Στρατιωτικα χρηματα, or money defigned to defray the charges of war. 3. The Θεωρικα, or money intended for pious ufes; in which they included the expences at plays, public fhews, and feftivals, &c. *Potter.* Archæol. Græc. T. 1. p. 82.

To each of thefe branches of the public revenue there was a *Treafurer* appointed, as Ταμιας τῆς διοικησεως, των στρατιωτικων and Θεωρικων.

TREATY (*Cycl.*)—in antiquity. For the folemn manner in which the Romans ufed to conclude *Treaties*, fee Liv. l. 1. c. 24. The ceremonies obferved by the Greeks in making *Treaties* may be feen in *Potter*, Archæol. Græc. l. 2. c. 6. T. 1. p. 252. feq.

In general it appears that the antients were very religious, grave and folemn in making *Treaties*; which were always confirmed by facrifices and mutual oaths, with horrid imprecations to the party that fhould break the terms of agreement.

TREBIUS, in ichthyology, a name given by Joannes Cuba and fome other writers, to the fifh called *phycis* by Ariftotle, Ælian, and Pliny; and *truca* and *tinea marina* by the later writers. It is nearly allied to the blennus clafs. See the article BLENNUS.

TRECHON, one of the many names by which the chemical writers, have called quickfilver.

TRECHEDIPNA, τρεχεδειπνα, in antiquity, a kind of livery or diftinguifhing habit worn by parafites; the wearing of which was a fufficient pafport to the tables of their patrons whofe livery it was. *Pitifc.* in voc.

The word comes from τρεχω, *I run*, and δειπνον, *a fupper*.

TREE (*Cycl.*)—Heat is fo effential to the growth of *Trees*, that we fee them grow larger and fmaller in a fort of gradation as the climates in which they ftand are more or lefs hot. The hotteft countries yield in general the largeft and talleft *Trees*, and thofe alfo in much greater beauty and variety than the colder do; and even thofe plants which are common to both arrive at a much greater bulk in the fouthern, than in the northern climates; nay, there are fome regions fo bleak and chill, that they raife no vegetables at all to any confiderable height. Greenland, Iceland, and the like places, afford no *Trees* at all; and what fhrubs grow in them are always little and low.

In the warmer climates, where *Trees* grow to a moderate fize, any accidental diminution of the common heat is found very greatly to impede vegetation; and even in England, the cold fummers we fometimes have, give us an evident proof of this; for tho' the corn and low plants have fucceeded well enough, and goofeberries, currants, rafberries, and other low fhrubs, have brought forth fruit in fufficient plenty, yet the production of taller *Trees* have been found very much hurt; and walnuts, apples, and pears have been very fcarce among us.

Heat is heat be it from what caufe it will, and acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal fires in ftoves, is found to fupply the place of the fun.

Great numbers of the Indian *Trees* in their native foil flower twice in a year, and fome flower and bear ripe fruit all the year round; and it is obferved of thefe laft, that they are at once the moft frequent and the moft ufeful to the inhabitants; their fruits, which hang always on them in readinefs, containing cool juices, which are good in fevers, and other of the common difeafes of that hot country.

Plantations of ufeful *Trees* might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be alfo benefitted by it, fince it would raife a continual fupply of timber ufed in fhip-building, and on other public as well as private occafions.

We have in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public to bring thefe to be truly valuable. Many, if not all of thefe heaths, would be found on trial capable of producing *Trees*; and fome of them are truly the

the remains of deftroyed forefts; and though the profit to be reaped from the planting them would come late, yet the expence of doing it would be very trifling in comparifon of that profit, and the means eafy.

The authors who have given rules for planting, having employed themfelves only about fmall fpots of ground, the eftablifhing orchards or parks, are by no means to be fuppofed proper guides in attempts of this kind; and Monfieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who feem to fpeak of every thing from their own experience, found when he fet about large plantations, that their opinions and rules were erroneous; and was obliged to have recourfe to experiments only; which he varied a thoufand ways: and though many of them proved unfuccefsful, yet they all gave hints toward others, by which the attempt might afterwards be brought to fucceed.

This fagacious enquirer into the operations of nature in the growth of vegetables, having fet apart a confiderable quantity of land for the trial, and procured a number of young *Trees*, firft divided the whole quantity into a number of fmall fquares, and having made a plan of it, examined the nature, depth, and other circumftances of the foil in each, and minuted the whole down on a proper part of the plan: that himfelf or whoever fucceeded him might judge from the different growths of a number of *Trees* planted in the fame ftate in thefe different foils, the different advantages and difadvantages of every circumftance in the depth and nature of the ground, in regard to the growth of ufeful *Trees*. Different numbers of labourers were employed about different fpots of this ground, and the acorns for the young growth planted at different feafons; but the refult in general was, that what fhould feem the beft methods fucceeded the worft; and thofe pieces where many labourers had been employed, and the acorns planted before winter, were much thinner of young oaks, than thofe where the leaft labour had been beftowed upon the ground, and where the acorns had been planted in the fpring: but thofe places which fucceeded beft from the fowing, were thofe which had the acorns planted in holes made by a pick-ax, without any preceding culture of the ground. And thofe where the acorns had only been laid upon the earth, under the grafs, afforded a great number of vigorous young *Trees*, though the greater part had been carried away by birds and other devouring animals. Thofe fpots of ground where the acorns were fet at fix inches depth, were much worfe furnifhed with young fhoots, than thofe where they had been buried but at an inch deep; and in fome places where they were buried at a foot deep not one fhoot appeared, though in others where they had been buried at nine inches there were many.

Thofe acorns which had been fteeped for eight or nine days in wine lees, and in the water of the common fewers, appeared out of the ground much earlier than thofe which were put in without this previous management.

But the moft fuccefsful of all the trials, was that of planting in the fpring fuch acorns as had been fown together in another place, and had time to fhoot there; of thefe fcarce any one failed, and the plantation was perfectly flourifhing, tho' the growth of thefe young fhoots was not fo quick or vigorous as thofe of the acorns, which had remained when firft fown; which was probably owing to the injury the tender radicles received in tranfplanting.

Thus fucceeded the experiments by fowing, while of thofe made by planting young *Trees*, fuch as had been brought out of woods and places under covert, fucceeded much worfe than thofe which had grown in more expofed places.

The young *Trees* of the feveral parts of the plantation kept on their growth in the manner they had begun to fhoot, thofe of the more laboured parts continuing more weak, and lower than thofe of the lefs laboured.

Thus were a number of neceffary experiments carefully tried, and the refult of the whole was, that to make a plantation of oaks, on a foil of the common clayey or loamy kind, the moft fuccefsful method is this: The acorns muft be preferved during the winter in the earth in this manner: let there be made a bed of earth of fix inches deep, on this place a layer of acorns two inches deep, over thefe lay a bed of another half foot of earth, over that another layer of acorns, and fo on fucceffively, till as many are employed as there will be occafion for; the whole is then to be covered with a foot depth of earth, to preferve all from the froft. In the beginning of March thefe beds are to be opened, and the acorns which will by that time have fhot out, and are then in reality fo many young oaks, are to be planted out at a foot diftance each, and the fuccefs of a plantation of this kind need not be feared. This is a manner of planting that is done at a fmall expence, and even that might be in a great meafure fpared, were it not for the birds and other devouring animals; fince, could the acorns be defended from thefe, they might be only laid on the furface of the ground under the grafs in autumn, and they would infallibly fhew themfelves in fo many young oaks the fucceeding fpring.

It is eafy to continue the carrying the acorns, when taken out of their winters bed, to the place where they are to be planted, without doing them much injury; and the fmall ftop the tranfplanting puts to their growth, is in reality rather an advantage than an injury; fince it only retards the young fhoots for about three weeks, or lefs than that: and by that means fecures them from the few cold mornings that may be expected about the time of their natural appearance. Memoires Acad. Scien. Paris 1739.

Trees in corn fields are a worfe enemy than any weeds, they fuck up the nourifhment from the corn about them, even to a great diftance: nor is it peculiar to corn to fuffer by them. Mr. Tull gives an inftance of a fingle *Tree* ftanding in a field of turneps, which fpoiled no lefs than half an acre of the crop. It has been fuppofed that *Trees* injured thefe lower herbs by their fhadow; and fome thought that the mifchief they faw from them, was owing to their droppings; but by this inftance, it is plain both thefe conjectures are erroneous: the fouth fide of the *Tree*, where no fhadow comes, is found to fuffer as much as any other; and the droppings reaching only as far as the bows, and the mifchief fo much farther, it is plain that the mifchief is owing to neither of thefe caufes, but to the *Tree*'s drawing all the nourifhment, by extending its roots fo far, and in fuch numbers, on every fide the extent of ground through which the turneps were thus injured, probably fhewing the extent of the roots of the *Tree*, which are found by this to run farther than is ufually fuppofed.

On felling of *Trees*, letters have fometimes been found in the midft of them. We have inftances of this kind, mentioned in the Phil. Tranf. N°. 454. Sect. 16. Where the trunk of of a beach being fawed, difcovered feveral letters in the wood, about one inch and an half from the bark, and near the fame diftance from the center of the trunk. It feems thefe letters had been formerly cut into the bark, and in procefs of time thefe might be covered. See the place cited. See alfo the fame number Sect. 17. in the remarks.

In the fame Tranfaction, we have an account of the horn of a deer, found in the heart of an oak. Crucifixes have alfo been found in *Trees*, and were to be fure fhewn as miraculous to the ignorant. See p. 236. of the faid Tranfaction in the remarks.

Trees are often found buried in the earth. See the article *Foffile* Wood.

How Trees may be injured by froft. See the article Frost.

Fruit-Trees. See the article Fruit-*Trees*.

Juices of Trees. See the articles Juice and Sap.

Diftemperature of Trees. See the article Distemperature.

Felling of Trees. See the articles Felling and Timber.

Trees in a fhip are of feveral forts, as, *Chefs-Trees*, *Crofs-Trees*, *Roof-Trees*, *Wafte-Trees*, *Treffel-Trees*. See the article Chess-*Trees*, Cross-*Trees*, &c.

Roof-Trees, in a fhip, fmall timbers that bear up the gratings from the half deck to the fore-caftle, fupported by ftantions that reft upon the half deck.

TREENELS, in a fhip, long pins or nails of wood, whence they are called *Tree-nells*, or *Tree-nails*, made out of the heart of oak, to faften the planks to the timber; and thofe have always oakam driven into them to prevent any leak.

TREET, *Triticum*, in our ftatutes, is ufed for fine wheat. See Statute 51. Hen. 3. *Blount*.

TREFOIL, *Trifolium*, in botany, the name of a genus of plants; the characters of which are thefe: The flower is of the papilionaceous kind: The piftil which arifes from the cup finally becomes a capfule, which remains covered with the cup, and ufually contains kidney-fhaped feeds. To this it is to be added, that the leaves grow three on every ftalk; though there are fome inftances of thefe plants truly of this genus, which have four or five on the ftalk.

The fpecies of *Trefoil*, enumerated by Mr. Tournefort, are thefe: 1. The bituminous, or ftinking *Trefoil*. 2. The common purple meadow-*Trefoil*. 3. The larger purple *Trefoil*, with longer and narrower leaves, and deeper coloured flowers. 4. The common white-flowered *Trefoil*. 5. The fmaller and fmoother white-flowered meadow-*Trefoil*, called by fome the female meadow-*Trefoil*. 6. The white meadow-*Trefoil*, with a bivalve pod, a hollow ftalk, and leaves marked underneath with purple fpots. 7. The bladder purple *Trefoil*. 8. The wild hop-*Trefoil*. 9. The fmalleft hop-*Trefoil*. 10. The mountain hop-*Trefoil*. 11. The large purple mountain-*Trefoil*. 12. The purple mountain-*Trefoil*, with fharp pointed and crenated leaves. 13. The purple mountain-*Trefoil*, with obtufe-pointed crenated leaves. 14. The leffer purple mountain-*Trefoil*. 15. The white mountain-*Trefoil*. 16. The *Trefoil* with a round red fpike, called the greateft lagopus or hares-foot *Trefoil*. 17. The *Trefoil*, with an oblong red fpike. 18. The mountain-*Trefoil*, with a very long red fpike. 19. The narroweft-leaved fpiked mountain-*Trefoil*. 20. The narrow-leaved Spanifh *Trefoil*, with a pale red fpike. 21. The narrow-leaved Spanifh hares-foot *Trefoil*, with very red flowers. 22. The common fmall-fpiked field-*Trefoil*, called common lagopus, or hares-foot *Trefoil*. 23. The fmall hares-foot *Trefoil*, with fharp-pointed and not crenated leaves, and fmall pale purple flowers. 24. The yellowifh flowered hares-foot *Trefoil*, called the meadow-*Trefoil*, with fulphur-coloured flowers. 25. The ftarry-headed *Trefoil*, with globofe hufks. 26. The common purple ftarry-headed French *Trefoil*. 27. The fmall ftarry-headed *Trefoil*, or dipfacus-headed *Trefoil*. 28. The globofe *Trefoil*, or round-headed

headed hares-foot *Trefoil*. 29. The creeping globofe headed *Trefoil*, or bur-headed *Trefoil*. 30. The fmooth or woolly-headed *Trefoil*. 31. The larger foft-headed, or woolly-headed *Trefoil*. 32. The larger rough-headed *Trefoil*. 33. The fmaller rough-headed *Trefoil*. 34. The thyme-headed *Trefoil*. 35. The *Trefoil*, with oblong rough heads. 36. The ftrawberry-*Trefoil*, with heart-fafhioned leaves and red flowers. 37. The ftrawberry-*Trefoil*, with deep violet-coloured heads. 38. The long-leaved purple ftrawberry *Trefoil*, which feems only a variety of the former fpecies. 39. The reticulated *Trefoil*, which buries its feed under ground. 40. The annual *Trefoil*, with heads like thofe of dodder. 41. The little procumbent *Trefoil*, with heads covered with a thick woollynefs. 42. The fmall hairy *Trefoil*, with large feeds, and foft heads in the alæ of the leaves. 43. The *Trefoil*, with round heads at the knots of the ftalks. 44. The blackifh luxuriant *Trefoil*, with four, five, or fix leaves on a ftalk, called the quadrifolium hortenfe. *Tourn.* Inft. p. 405.

Trefoil, or clover, is a plant greatly efteemed by the Englifh farmers, for the great improvement it makes upon land, the goodnefs of its hay, and the value of its feed. The great advantage of *clover*, or *Trefoil*, to the land on which it grows is, that it feeds a vaft number of cattle at a time, and their dung is fo rich a manure to the ground that in two or three years time it becomes fit for corn again, though it had been ever fo much exhaufted before. Clayey lands, in particular, are greatly improved by it.

There are feveral kinds of *clover*, but the great fort is efteemed the beft, whofe feed is like that of muftard, except that it is more oblong. The Englifh feed is preferable to that of all other places, and the farmer fhould choofe fuch as is of a greenifh colour, with a caft of red; that which is black never growing fo well. An acre of land will require ten pound of feed, fometimes twelve pound, and it is better to fow too much than too little. It delights moft in a rich warm foil, and always thrives beft in thofe lands which have been well dunged or manured; but the clay-lands, which are long in acquiring a coat of grafs, or fwarding as the farmers exprefs it, and are little fubject to weeds, are of all others the beft land for *clover*; becaufe in thofe lands, where the common grafs grows fpeedily, it foon eats out the *clover*. Light lands are in general more fubject to this fudden growth of common grafs, and they have alfo another difadvantage in regard to the *clover*, which is, that they eafily wafh away from its roots after fharp rains; and then the roots, being left bare, are killed by the firft froft that comes; in good grounds it will bear crops for three or four years; but not longer than that, even in the moft proper foil, and with all the neceffary cautions.

There is a very eafy method of determining what is good *clover*-feed and what bad; it is only neceffary to throw it into a glafs of water, and that which finks is good, what fwims is bad, and will never vegetate. It is eafy, from this trial, to know what feed is to be depended upon, and what is not; and to know what allowance is to be made in bad feeds, for the quantity loft in the proportion for every acre.

The beft way of fowing of *clover* is, either with barley or oats after the corn is fown; and, upon this account, the corn is to be fown fomewhat thinner than ordinary. The ufual time of fowing it, is in the end of March, or the beginning of April in a calm day; but if the land be very dry, it is better to fow it with black oats, as early in the fpring as may be, that fo it may get up while the fpring rains laft, and be of fome ftrength before the dry weather comes. Some fow it with wheat or rye at Michaelmas; this gives it an opportunity of fhedding its feed on the ground, and by that means, the crop of the next year is rendered much ftronger than it would have been made by any other means; but then it is beft to be fown upon dry lands, which will bear the fowing both of the wheat and the rye upon broad ridges; which is ufually very fuccefsful, if a mild winter follows; but if there are long and fevere frofts, or deep fnows, it is very hazardous. Some advife the fowing it alone, at Michaelmas; which they fay makes it come up the freer from weeds, than if fown in the fpring; and that it will get ftrength enough before winter, to fupport itfelf againft the frofts, and will grow finely in the enfuing fpring.

Some farmers fow rey-grafs with the corn at Michaelmas, and early in the fpring they fow *clover*, which they only cover by rolling it. The beft management of all feems to be the feeding it bare before winter comes on, and then it is fafe; for the frofts, though they often deftroy the leaves of the *clover*, yet never hurt its roots, unlefs they happen to lie bare. About the middle of May, or at the utmoft toward the end of that month, is the time of mowing the *clover* for the firft crop. This takes up more time and labour in the making into hay, than the common grafs, and muft be well attended; but if it grow not too ftrong, it will be found exceeding rich for the fattening of cattle. The exact time for the cutting this firft crop is when it begins to knot, and after this fome mow two other crops before winter. *Mortimer*'s Hufb. p. 32. feq.

Hop-Trefoil, or *Hop-Clover*, the farmers name for the fmaller fpecies of *Trefoils*, or three-leaved grafs, which they fow in many places inftead of the large clover: it is efteemed much finer and fweeter than the large clover, and upon fome land is a very great improvement, though 'tis reckoned to grow upon any foil.

Hartlip, in his legacy, fays, there are twenty-three forts of it, and that every fort loves a peculiar foil; fome fpecies thriving beft on clay, fome on fand, fome in watery places, and fome on fun-burnt grounds. The feeing one kind or other of it thus growing on all forts of foils, may have been the occafion of the error of fuppofing that every kind of it would grow every where: there are very certainly fometimes feen thin crops of it, and the moft natural fuggeftion as to the reafon of it, feems, that a wrong kind for the foil has been fown there. It may be no fmall improvement in this branch of the farmer's bufinefs, to find out which it is that particularly loves each foil, and always fow the proper fpecies in the proper places. *Mortimer*'s Hufbandry, p. 41.

It may be fown either with corn, or alone on ploughed lands, or fprinkled over meadows to make a better crop with the common grafs. They commonly allow twelve pounds of the feed to an acre; and when fown alone, it is efteemed much more lafting than the rey-grafs, efpecially the yellow hop-clover. When fown among the hay-grafs in meadows, it much improves the crop both in quantity and quality.

The laft crop is, however, often damaged by the weather, and it feems, upon the whole, better for the farmer to make only one crop after that in May. This fecond crop he fhould alfo calculate to get feed from; and for this purpofe he muft let it ftand till the heads are thoroughly ripe before it is cut, for it is a fort of feed that is not eafy to fhed.

When the feed is firft perceived in the head, it is a notice that in a month's time it will be ripe, and fit for cutting. It muft be watched about this time, and the ftalk will be found to turn brown, and the feed greenifh, at the time when it is fit for cutting. It muft be mowed in a dry feafon, and kept carefully as dry as can be.

It ripens fome years confiderably fooner than others, and therefore there can be no rule laid down for the time of cutting, but this muft be guided by the ripening of the feeds in the heads.

If the clover is apt to wear out the ground, and become thin upon it, let it be mowed in May, and after that let it ftand till the feed is ripe, and falls out of the hufks upon the ground; then cattle may be turned in to feed upon it, and it will rife up as frefh and full from thefe fcattered feeds, as if it had been new fown with all the art and care in the world. One acre of this grafs will feed as many cattle as five acres of common grafs; but the moft advantageous way of feeding them, is not to turn them in upon it, becaufe in that cafe they tread down more than they eat; but to cut it with a fcythe, and give it them in racks.

If the cattle are to be turned in to feed at large upon it, this muft be done gradually, and with great caution; for if they are at once removed from common grafs into this, they will over-feed upon it, and even burft themfelves; they are therefore to be put in at firft only for half an hour in the middle of the day; a fecond day they may be left in an hour; and the third day two or three hours; and after this, for three or four days, they are to be turned in as foon as the morning dews are off the ground, and driven out again before the evening dews fall. After this, it may be fafe to let them remain in it entirely.

Clover is apt to do harm to milch cows, more than to any other cattle; and it is a very good method fome have, to take off from the too great richnefs of the crop, by fowing rey-grafs among the *clover*. This upright grafs grows well among the branches of the *clover*, fhooting up its ftalks above it, and being eaten with the *clover*, takes off from its too great richnefs, at the fame time that it makes the crop the larger.

The *clover* that is intended for feed is preferved dry all the winter, and in March it is to be thrafhed for the feed: what feed firft comes out is to be cleanfed from the ftraw, and the hufks then are to be trafhed again. When all is obtained that can at one time, let the ftraw be well dried in the fun, and toffed about with a rake, and then on the thrafhing it again, more feed in confiderable quantity will be obtained: two bufhels of feed may thus be procured, out of the produce of an acre of good Land where the *clover* has throve. Id. ibid.

Shrub-Trefoil. See the article Cytisus.

TREMELLA, *Laver*, in botany, the name of a genus of fmall and feemingly imperfect plants, the characters of which are thefe: They are a kind of plants feemingly of a fort of a middle nature between the *alga* and *conferva*. Thefe produce no flower, nor feed, fo far as has been yet obferved, but are throughout of one uniform and tender texture, pellucid and membranaceous, and frequently gelatinous; they for the moft part live in the water, and confift of flat and plain leaves, often very broad, and fometimes tubular. See Tab. of Moffes, N°. 3. *Dillen.* Hift. Mufc.

There are feventeen known fpecies of this plant. 1. The common fea *Tremella*, called oifter-green or fea-*Laver*. 2. The frefh-water *Laver*: this is much fmaller than the former, and of a very tender ftructure. 3. The navel-*Laver*: this is diftinguifhed by having its leaves rounded and umbilicated in the center. 4. The marygold-leaved *Laver*: this is of a blackifh green colour, and has all its leaves oblong, jagged, and growing on pedicles. 5. The leek-leaved *Laver*: this grows

grows to three or four inches long, and is of a pale green. 6. The fasciated, or double ribband-*Laver*: this is of a bright green, and finely undulated. 7. The gut-*Laver*, commonly called the sea-chitterling: this is hollow and waved in various manners; it is common in salt-water ditches. 8. The thready and tape-like *Laver*: this is naturally of a fine green, but becomes white with long lying on the shores. 9. The small cluster-*Laver*: this consists of small and convoluted branches, forming a thick tuft; it is of a dusky green, and is common on pebbles near the sea-shore. 10. The jelly-like buckthorn sea-*Laver*: this is common on the sides of small salt-water ditches, and is of a fine bright green; the branches are somewhat distended, but not wholly cylindric. 11. The gelatinous fern moss-like *Laver*: this is a very beautifully ramified species, and grows on small pebbles; it is very tender and of a beautiful green. 12. The tender crisp or curled ground-*Laver*: this of a beautiful deep green, and is very common under old walls and pales, in January, February, &c. 13. The horned ground-*Laver*: this grows to three or four inches high, and is variously and elegantly divided into a number of branches, or horns; those are of a membranaceous structure, and of a pale green colour when growing, but a little yellowish when dried: while growing, it much resembles some of the lichenoides. 14. The jelly rain-*Laver*, called *nostoch*. See the article NOSTOCH. 15. The black gelatinous tree-*Laver*, called by the country-people witches butter: this is of a dusky-reddish black, and consists of a thick wrinkled membranaceous substance; it is common in Herefordshire, and some other countries on the barks of old trees. 16. The bladdery gelatinous river-*Laver*: this is corrugated in the manner of the mesentery, and is covered with granulous tubercles resembling seeds; it is of a bright green, and is found in the rivers of Wales. 17. The bladder-headed-*Laver*: this arises from a greenish irregular crust, into a sort of hollow tubercles or bladders, which at first lie close upon it, but afterwards rise upon small pedicles; these heads or bladders are distended each by a drop of water, which when it is rarified by the sun's heat often bursts the bladder, and the whole collapses and looses its form. *Dillen.* Hist. Musc. p. 50.

TREMOLANTE, in the glass-trade, a name for the preparation of calcined brass, otherwise called orpello, used either for a sky-blue, or a sea-green. *Neri's* Art of Glass, p. 35.

TREMOR (*Cycl.*)—TREMOR *Artuum*, in medicine, a distemper consisting in a violent agitation of the limbs in contrary directions, owing to a deficiency of the due tone and proper nisus of the affected parts. Medical writers distinguish this *Tremor* into the active and passive; the active is that which happens in violent passions of terror, anger, joy, &c. or in intermittent fevers, and is to be referred to the semi-convulsive motions; the passive are owing to a privative cause, and are allied to the semi-paralytic affections.

The passive *Tremors* of the limbs, when considered as a disease, are to be distinguished from those which are caused by external accidents, such as the being plunged into cold water, the drinking tea, coffee, or other warm liquors, in many constitutions, and other such accidental causes. The persons subject to *Tremors* of the limbs are principally old people, in whom the vital principle is weak and languid.

Causes. The internal causes, are a flaccidity of the nerves and remission of the tone of the parts; the external and accidental ones are the omission of accustomed evacuations, a diaphoretic regimen, and an abuse of spirituous liquors. *Junker's* Consp. Med. p. 680.

Prognostics and Method of Cure. This is usually in old people a very obstinate complaint, and the more it is confirmed by being grown habitual, the more difficult is the cure; but if a case of this kind be taken in hand, as soon as it seizes the patient, and be treated in a rational manner, it is often perfectly cured. In order to this, the first step must be the perfectly cleansing the *primæ viæ*, by repeated doses of rhubarb, or of an extract of black hellebore; if any habitual evacuation have been omitted, as bleeding or the like, this must be restored in the accustomed manner; and if any natural flux of blood by the hæmorrhoids or otherwise have stopped, this also must be recalled by proper medicines, or by the application of leeches: after this the due tone of the parts is to be restored by nervine medicines, as by wine impregnated with serpyllum, lavender, sassafras, guaiacum, and the like ingredients; and externally by rubbing the parts with spirit of castor and serpyllum, and bathing them in decoctions of tanzy, savin, feverfew, and the like herbs. One great rule in the cure of this disease, is, that the patient is to abstain from all hot things, otherwise an atrophy is easily brought on, and proves a much worse thing than the original disorder. *Junker's* Consp. Med. p. 681.

TRENCHING *Plough*, (*Cycl.*) in husbandry, the name of an instrument used to cut out the trenches, drains, and carriages in meadow and pasture-ground. It is also used for cutting the sides of turf even, which are to be laid down again either in the same, or in some other places.

It consists of a long handle, with a knob or button at the end, and at the other end it turns upward like the foot of a plough, to slide in the ground. In this part is placed a coulter, of the length proportioned to the depth to be cut, and with a sharp edge; this has two wheels to make it run easy, and does a great deal of business in a very little time. *Mortimer's* Husbandry.

TREPAN (*Cycl.*)—Where it is ambiguous whether there be an extravasation of liquors, or a depression of the skull, the operation of the *Trepan* is said to be the safest method. Mr. Quesnay gives us some histories of the *Trepan* being performed several times with success, for the same disease; and of large parts of the skull being taken away, without loss of the patient's life. See Mem. de l'Acad. de Chirurg.

We have the description and figure of a *Trepan*, differing from and turning more equally than the common, by Mr. Monro, in the Med. Ess. Edinb. vol. 5. art. 41.

TREPANING (*Cycl.*)—Not only the head, but the sternum, is sometimes necessarily the subject of this operation, as abscesses are sometimes formed under the sternum between the membranes of the mediastinum, by a fall or blow, an inflammation, or other causes; in which cases there is hardly a possibility of discharging the matter by any other method.

The great difficulty is to determine when and when not this is necessary; that is, when there really is an abscess formed there. When this is known to be the case, the operation is to be performed in the following manner: The patient is to be inclined backward, and a crucial incision made in the integuments upon the lower part of the sternum, where the abscess sometimes makes a point; then the integuments being freed from the sternum, the *Trepan* is to be applied, and worked in the same manner as in *Trepaning* the cranium; and when the perforation is made, the patient is to be stooped forward, and ordered to cough or breathe hard, in order to promote the discharge of the matter; and the abscess is afterwards to be cleansed with detergent injections, and healed in the usual way. *Heister's* Surgery, P. 2. p. 21.

TREPIGNER, in the manege, the action of a horse who beats the dust with his fore-feet in managing, without embracing the volt; and who makes his motions and times short, and near the ground, without being put upon his haunches. This is generally the fault of such horses as have not their shoulders supple, and at liberty, and withal have scarce any motion with them. A horse may *trepigner*, in going upon a strait line.

TRESSEL (*Cycl.*)—TRESSEL-*Trees*, in a ship, are those timbers of the cross-trees that stand along ships, or fore and aft at the tops of the masts. See the article CROSS-*Trees*.

TRESSIS, among the Romans, a copper coin equal in value to three *asses*. *Pitisc.* in voc. See the article As, *Cycl.*

TREWIA, in botany, the name of a genus of plants, the characters of which are these: The perianthium is permanent, and is composed of three oval reflex and coloured leaves. There are no petals. The stamina are numerous capillary filaments, of the length of the cup. The antheræ are simple. The germen of the pistil is placed under the cup. The style is simple, and of the length of the stamina, and the stigma is simple. The fruit is a three-square turbinated coronated capsule, formed of three valves, and containing three cells. The seeds are single, and are in figure convex on the one side, and angular on the other. *Linnæi* Gen. Plant. p. 236. Hort. Mal. vol. 2. p. 42.

TRIAD, *Trias*, (*Cycl.*) among the antient Mythologists. See the article TERNARY.

TRIANDRIA, in botany, a class of plants which have hermaphrodite flowers, with three stamina or male parts in each.

The word is formed of the Greek, τρὶς, three, and ἀνὴρ, male. Of this class of plants are the valerian, saffron, a great many of the grasses, &c. See Tab. 1. of Botany, Class 1.

TRIANGLE (*Cycl.*)—Plutarch informs us, that Xenocrates the philosopher resembled the Deity to an equilateral *Triangle*, the genii to an Isosceles, and men to a scalenum. A *Triangle* has since been applied by Christians to represent the Trinity, sometimes single, and at other times with additional lines, expressing a cross. Thus we find them variously combined upon the medals of the popes, published by Bonanni. And nothing was more frequent formerly with printers, than to place these figures in the front of their books; at first, doubtless, with a religious intent, till at length, by common use, they became only press marks, and badges of distinction among the trade; as they now are with merchants, who mark their goods with them both here and abroad. Phil. Trans. N°. 474. Sect. 1.

TRIANGULAR (*Cycl.*)—TRIANGULAR *Leaf*, among botanists. See the article LEAF.

TRIANGULARIS (*Cycl.*)—TRIANGULARIS *Coccygis*, in anatomy, a name given by Santorini, and others, to the muscle now generally called simply *Coccygæus*. See the article COCCYGÆUS.

TRIANGULARIS *Labiorum*, in anatomy, a name given by Santorini and Winslow, to the muscle called by Albinus *depressor anguli oris*, and by Cowper and others, *depressor labiorum communis*.

TRIANGULARIS *Penis*, in anatomy, a name given by Morgagni, and others, to a supposed muscle, called also by some *dilatator penis*, and *dilatator posticus urethræ*; and by others *levator ani*.

It is truly no distinct muscle, but a process of the *sphincter ani* running into the perinæum.

TRIAN-

Triangularis *Piscis*, in zoology, the name of a sea-fish of a very remarkable figure, called in English the *coney-fish*, of which there are two species, the one having two horns, the other wanting that character.

The horned kind is usually six or seven fingers breadth long, and about three fingers broad. The tail ends in a somewhat long fin. The mouth is small, and capable only of admitting a pea. It has twelve strong serrated teeth in the upper jaw, and eight larger ones in the lower. The head rises gibbously from the mouth to the horns; and the back is humped in the same manner in the middle. It has only one small fin near the tail. Its eyes are large, and placed near the horns. Beside the single fin near the tail, it has four others, the tail making one, one more being situated on the back, and two on the belly. It has two horns like cocks spurs, growing strait out of its forehead, and two others in a contrary direction, out of its belly near the tail. It has no scales, but has a hard skin, white on the belly, and brown every where else, and wonderfully marked with trigonal, tetragonal, and pentagonal and hexagonal figures. The species which has no horns, has a broader belly, a longer tail, and is marked all over its body only with hexangular figures, and innumerable small tubercles. Its belly is yellowish, and the rest of its body of a greyish or brownish yellow. The mouth is narrow, and the teeth small; five in the under, and eleven in the upper jaw. The eyes are large and round. It is hollow, and has very little flesh. See Tab. of Fishes, N°. 68.

Both those species are caught among the rocks, on the shores of the island of Java, and are sometimes eaten by the inhabitants, being first skinned. *Clus.* Exot. L. 6. c. 27. *Willughby*'s Hist. Pisc. p. 150.

Triangularis *Splenii*, in anatomy, a name given by Spigelius and others, to a muscle of the head called by Winslow, the upper portion of the *splenius*, or *superior mastoidæus*, and by Albinus, the *splenius capitis*. The old authors have described it under the name of the *primus caput moventium*.

TRIBULASTRUM, in botany, a name given by Jussieu to a genus of plants, since called by Linnæus *neurada*. See the article Neurada.

TRIBULOIDES, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, being composed of a number of petals, arranged in a circular form. From the cup arises a pistil, which finally becomes, together with the cup, a roundish prickly unicapsular fruit, containing a seed like a chesnut. The prickles of the fruit are only the leaves of the cup become rigid. There is only one known species of this plant, which is the water *Tribuloides*, commonly called the *water Tribulus*. The kernel of the fruit is eatable.

TRIBULUS, *Caltrop*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, consisting of several leaves, arranged into a circular form. From the cup arises a pistil, which afterwards becomes a sort of cruciform or turbinated fruit, composed of several parts, each ending in a prickly point, and all collected into a firm head, and containing oblong seeds.

The species of *Tribulus*, enumerated by Mr. Tournefort, are these: 1. The chich-leaved land *Tribulus*, with prickly seed-vessels. 2. The great prickly-headed land *Tribulus* of Curasso 3. The long-leaved Armenian *Tribulus*, with turbinated heads. And 4. The vetch-leaved hairy *Tribulus* of the East-Indies. *Tourn.* Inst. p. 265.

Tribulus *Murinus*, the *Caltrop-Shell*, in natural history, the name of a peculiar species of the purpura. It is of a whitish colour, and has three rows of spines. See the article Purpura.

TRIBUNES *of the People*, (*Cycl.*) in antient Rome, by virtue of their office, claimed and exercised a power of summoning the senate at any time, whenever the affairs of the people required it, though the consuls themselves were in the city. It has been taken for granted, on the authority of Valerius Maximus, that the *Tribunes* of the people, on their first creation, were not admitted into the senate, but had seats placed for them before the doors in the vestibule. But we may reasonably conclude, that a magistrate so ambitious and powerful, who could controul, by his single negative, whatever passed within doors, would not long be content to sit without. *Dionys.* Halic. x. 31. *Middlet.* of Rom. Senat. p. 129. *Val. Max.* l. 2. c. 27.

A. Gellius says, that they were not made senators before the law of Atinius [a], who is supposed to be C. Atinius Labeo, *Tribune* of the people, A. U. 623. [b]; but that cannot possibly be true, since it is evident from the authority of Dionysius, that near four centuries before, the *Tribunes*, by the mere weight, and great power of their office, had gained an actual admission into the senate, within two years after their first creation [c]; in which we find them debating and enforcing, with great warmth, the demands of the commons, for a liberty of intermarriages with the nobles, and the choice of a plebeian consul [d]. So that the intent of this Atinian law could not be, as it is commonly understood, that the *Tribunes* should be senators in virtue of their office, for that they had been from the beginning; but that for the future they should always be chosen out of the body of the senate, or, which is the same thing, out of those who had already borne the office of quæstor [e]. —[[a] *A. Gell.* 14. 8. [b] V. *Pighil.* Annales, A. U. 623. [c] *Dionys.* l. x. 11. [d] *Dionys.* xi. 57. [e] *Middleton*, of Rom. Sen. p. 45.]

TRICEPS (*Cycl.*)—Triceps *Primus*, a fleshy and flat muscle, situated between the os pubis and the whole length of the os femoris; the first and second cross each other in such a manner, as that the muscle which is the first on the os pubis, becomes the second on the os femoris; but the third keeps its rank.

The *Triceps primus* is fixed above by a short tendon to the tuberosity or spine of the os pubis, and to the neighbouring part of the symphysis, its fibres mixing a little with those of the pectineus. From thence it runs down, increasing in breadth, and is inserted by fleshy fibres interiorly in the middle portion of the linea femoris aspera. At the lower part of this insertion a portion of the muscle separates from the rest, and sends off a long tendon, which, together with a like tendon of the *Triceps tertius*, is inserted in the inner condyle of the extremity of the os femoris. *Winslow*'s Anatomy, p. 208.

Triceps *secundus*, a fleshy and flat muscle, fixed above by fleshy fibres below the superior insertion of the *Triceps primus* in all the outside of the inferior ramus of the os pubis, as low as the foramen ovale; but seldom so low as the ramus of the os ischium. This insertion is broader than that of the former muscle. From thence it runs down, and is inserted in the upper part of the linea aspera, between the pectineus and *Triceps primus*, mixing a little with each of those muscles. This insertion appears sometimes divided. *Winslow*'s Anat. p. 208.

Triceps *tertius*, a fleshy and flat muscle, fixed above by fleshy fibres to the anterior part of all the short ramus of the ischium, and to a small part of the tuberosity of that bone; this insertion covers some part of the tendon of the semi-membranosus; from thence it runs down and is inserted by fleshy fibres in the linea aspera, almost from the little trochanter down to the middle of the os femoris.

It goes lower down than the first *Triceps*, sending off a separate portion, like that of the secundus. These two portions join together and form a common tendon, which running down to the lower extremity of the os femoris is inserted in the back part of the tuberosity of the inner condyle; this separate portion is sometimes large enough to be mistaken for a distinct muscle, making a quadriceps instead of a *Triceps*. In all this progress this muscle is joined to the vastus internus by a perforated aponeurosis, through which the blood-vessels pass. *Winslow*'s Anatomy, p. 208.

TRICHECHUS, in ichthyology, a name given by Artedi to the creature commonly called the manati, or sea-cow. He makes it a distinct genus of the plagiuri or cetaceous fishes; the characters of which are these: The teeth are flat and stand in each jaw, and there is no fin on the back. This creature grows to twelve or fifteen foot in length, and to six or seven foot in breadth. The head is oblong and cylindric, and more resembles that of a hog than any other creature's. The eyes are small, there are small apertures in the head by way of ears, and the lips are very thick; two teeth stand out on each side, of the thickness of a man's thumb, and five or six inches long. The pectoral fins are two, and stand on the breast; they are composed of five distinct bones resembling fingers, joined together by a membrane; each bone has three articulations. The tail is placed horizontally, and there is no fin upon the back: In the females there are two round breasts placed between the pectoral fins. The parts of generation are like those of the human species in both the male and female; and there is a navel. The skin is hard, and almost impenetrable; the hairs are few, and of a greyish colour. The creature lives about the openings of great rivers into the sea, and feeds on grass and sea-plants. The flesh is white and well tasted. It makes a noise, and is said to be easily tamed, and to love the human species. Its great enemies are the crocodile and the shark, both which are very fond of its flesh. *Artedi* Gen. Pisc. 61. *Linnæi* System. Nat. p. 5.

The name is originally Greek, and is formed of the words θρίξ, a hair, and ἰχθύς, a fish. It is given this fish to express its being hairy; as it is almost the only fish in the world that has a title to this adjective hairy.

TRICHERIÆ, in natural history, the name of a genus of fossils, of the class of the fibrariæ; the characters of which are, that they are not elastic, and are composed of strait and continuous filaments. See Tab. of Fossils, Class 1.

The word is derived from the Greek τρίχες, capillaments or fibres. The bodies of this genus are divided into those which have broader, and those which have narrower filaments; and there are six known species of it: 1. The gypsum striatum, or striated plaster-stone; see the article Gypsum *Striatum*. 2. A yellowish white kind, found in the clay and gravel pits in Northamptonshire, and elsewhere. 3. A white kind, with foliaceous flakes, made up of several conjunct series of filaments, and emulating the external appearance of the talcs, though wanting their characters: This is found in the alabaster pits of Derbyshire. These three are of the broad fi-

bred kind. Of thofe with narrower fibres, there are, 1. A flefh-coloured fpecies, with very little glofs, found in many parts of Yorkfhire, and worth enquiring after, as it readily burns to a very fine plafter, like the gypfums. 2. A dull-looking white fpecies, with very fhort though continued filaments, found in the pits of red marl in Derbyfhire, and elfewhere. And, 3. A greenifh white kind very gloffy, with ftrait narrow and continued filaments. This is a very fcarce fpecies, but is found fometimes in the marl-pits of Derbyfhire and on the fhores of Yorkfhire, having been wafhed out of the cliffs by the waves in high tides. All thefe fpecies burn very readily to a fine plafter, like the gypfums; and fome of them are found in particular places in fuch great abundance, that it would be a very advantageous thing to collect and burn them. *Hill's* Hift. of Foff. p. 90.

TRICHESTRUM, in natural hiftory, the name of a genus of foffils, of the clafs of the felenitæ, but differing extremely in figure and ftructure from the common kinds.

The word is derived from the Greek τρίχες, hairs or filaments, and ἀστὴρ, a ftar; and expreffes a fet of bodies compofed of filaments arranged into the form of a ftar. The felenitæ of this genus are compofed of filaments fcarce any where vifibly arranged into plates or fcales, but difpofed in form of a radicated ftar, made of a number of disjunct ftriæ. See Tab. of Foffils, Clafs 2. *Hill's* Hift. of Foff. p. 123.

Of this genus there is only one known fpecies, which is of a pale brown, and is compofed of extremely fine and flender filaments. It is formed like the lepaftrum in the accidentally open cracks in the feptaria, or ludus Helmontii, and is no other way different from the bodies of that genus, than as in all the felenitæ the plates they are compofed of are made up of filaments nicely arranged, in this as in fome other of thofe bodies, the filaments have never arranged themfelves into plates at all, but are difpofed into the form of a ftar compofed of fingle threads. This body very readily and regularly fplits according to the arrangements of the fibres, and is in fome pieces tolerably pellucid. It is found only in one place, fo far as is yet known, which is under the cliffs of Sheppy-ifland in Kent; where it is confiderably plentiful, and makes a very elegant figure on the broken maffes of feptaria, which are in immenfe numbers ftrewed upon the fhore. *Hill's* Hift. of Foff. p. 150.

TRICHIASIS, in medicine, the name of a diftemperature of the eyes, in which the eye-lids are inverted, and in which the eye-lafhes hurt and irritate the eyes.

The cilia or margins of the eye-lids are fometimes inverted fo as greatly to irritate the fenfible coats of the eye, and bring on intenfe pains and inflammation, which, without timely affiftance, may greatly injure, if not totally deftroy the fight. This diforder is generally owing to accident, as the irregular cicatrix left on the part from a burn, the fmall-pox, an ulceration, or wound, or fome other external injury. But fometimes a relaxation of the fkin, and a paralytic diforder of the eye-lids, are the chief caufes of it.

Whatever caufe it is from, it is always difficult enough to be remedied; for it is hardly poffible for the furgeon to remove it, fo as to prevent its returning, without extirpating the offending hairs; and if thefe be cut off clofe, it will be to no purpofe, becaufe the rigid ftumps of the hairs will irritate the eye even worfe than the whole hairs did before. It is a very nice operation alone that can make a cure; here the hairs muft be pulled up fingly by the roots, and the places of their infertion fingly cauterized with a hot broad-pointed needle; but this the patient will feldom fubmit to, and the only remaining method then, is to fill up the finus's out of which they were extracted with the lapis infernalis. But in this the greateft care muft be taken, that no part of that application get into the eye. The eafieft method is the touching the cavities, out of which the hairs have been pulled up, with a pencil-brufh dipped in a mixture of fpirit of fal-armoniac and highly rectified fpirit of wine, by which means they will clofe up, and no more hairs will grow from them. *Heifter's* Surgery, p. 369.

TRICHIDES, in zoology, a name ufed by the antients, for a fifh of the harengi-form kind, probably the pilchard, which they called alfo *Sardinia* and *Sardella*. *Willughby's* Hift. Pifc. p. 224.

TRICHOMANES, in the Linnæan fyftem of botany, the name of a genus of capillary plants, defcribed by Plumier; the characters of which are thefe: On the margin of the leaves ftands a fingle erect turbinated cup, and a ftylus in the manner of a briftle terminates at the capfule. The plants of this genus are very different from what other authors call the *Trichomanes*; which, according to Linnæus, is not a diftinct genus of plants, but is a fpecies of afplenium. See Tab. I. of Botany, Clafs 16. and the article ASPLENIUM.

The characters of this genus, according to Mr. Tournefort, are thefe. The flowers are not difcovered, but the feeds grow in clufters on the backs of the leaves, as in fern. The leaves are compofed of little ufually roundifh leaves, which grow by pairs along a middle rib.

The fpecies of *Trichomanes*, enumerated by Mr. Tournefort, are thefe: 1. The common *Trichomanes*. 2. The *Trichomanes*, with leaves elegantly jagged. 3. The fmall tender *Trichomanes*. 4. The great branched *Trichomanes*. 5. The *Trichomanes* with round dents, furrounded by a black rim. 6. The *Trichomanes*, with leaves lightly prickly. 7. The *Trichomanes*, with triangular crenated leaves. 8. The *Trichomanes* with heart-fafhioned leaves. 9. The leffer branched *Trichomanes*. 10. The *Trichomanes*, with leaves partly bifid, partly whole. 11. The broad-leaved dentated *Trichomanes*. 12. The pendulous foft and filky *Trichomanes*. 13. The filvery *Trichomanes*, black at the edges. 14. The *Trichomanes* with bifid indentings.

The fruit of the *Trichomanes* is a roundifh capfule, of a membranaceous texture, and covered with a fort of fcales; thefe are furrounded with an elaftic ring, by the contraction of which they are burft, and the feeds thrown out. *Tourn.* Inft. p. 539.

This plant ferves with us, as a fuccedaneum for the true adiantum, or maiden-hair, which is not a native of England, and by the careleffnefs of our druggifts is feldom brought over to us. The whole plant, ftalks and leaves together are ufed, and the virtues are in their greateft perfection, if it be gathered in the month of September; it is fpoken of by all authors, as a good medicine in difeafes of the breaft and lungs, and is much recommended by fome in the ftone and gravel. *Dale*, Pharm.

TRICHOSANTHES, in botany, the name given by Linnæus to a genus of plants, called by Plumier, Micheli, and others, *anguina*: the characters are thefe: It produces male and female flowers, on diftinct parts of the fame plant; in the male flowers, the perianthium is one leaved, clavated, and very long; it is fmooth on the furface, and has a fmall mouth reflected backwards, and divided into five fegments. The flower is divided alfo into five fegments, it is fixed to the cup, and is plain and expanded; the fegments are of a lanceolated oval figure, and are fringed at their edges, with a great number of long and branched hairs: the ftamina are three very fhort filaments, reaching to the top of the cup; and each anthera is an oblong erect cylindric body, furrounded above and below with a line containing a large quantity of farina. There are in this flower three ftyles, which are very fmall, and grow to the fides of the cup, but they are always abortive. In the female flower, the perianthium is the fame as in the male, but it ftands in this upon the germen of the piftil, and foon perifhes; the flower is the fame with the male; the piftil has an oblong and flender germen, and has a capillary ftyle, arifing from it, of the length of the cup; the ftigmata are three in number, they are long, pointed, and gaping in the middle; the fruit is an extremely long pomum, and contains three cells, very remote one from another: the feeds are very numerous, and are compreffed, and of an obtufely oval form, and covered with a coat. *Linnæi* Genera Plant. p. 466. *Micheli*, Nov. Gen. p. 9. *Plumier*, Rar. p. 100. Hort. Malab. Vol. 8. p. 157.

TRICHOSTEMA, in botany, the name of a genus of plants, the characters of which are thefe: The perianthium is compofed of one leaf, and is bilabiated; the upper lip is divided into three fegments, and is twice as large as the under one, which is divided only into two. The flower confifts of one petal, and is of the labiated kind; its tube is very fhort; its upper lip is compreffed and falcated, and the lower is divided into three fegments, the middle one is oblong, and is the fmalleft of the whole; the ftamina are four capillary filaments, they are crooked and extremely long, two of them are fomething fhorter than the others; the antheræ are fimple; the germen of the piftil is divided into four parts; the ftyle is capillary and of the length of the ftamina; and the ftigma is bifid; the cup remains after the flower is fallen, and then becomes larger and the upper lip falls over the under one, it then becomes diftended in the middle and clofed at the mouth, and contains four feeds. *Linnæi* Gen. Plant. p. 265.

TRICHOURI, in natural hiftory, a term ufed by fome authors to exprefs fuch flies, as have one or more hairs growing out at their tails; thefe are called alfo feticaudæ, and are diftinguifhed into three genera, as they have one, two, or three hairs growing out at the tail. See the article SETICAUDÆ.

TRICHRUS, in natural hiftory, the name of a ftone defcribed by the antients, and faid to yield three colours; in their common way of preparing bodies of this kind for medicinal ufe, (which was by rubbing them down on a porphiry, or other hard ftone with water) this firft coloured the water black, then red, and laftly white. It feems to have been a kind of hæmatites, or blood-ftone.

TRICIPITIS *Caput Primum*, in anatomy, a name given by many authors to a mufcle of the thigh, called by Albinus *abductor femoris*; Douglafs calls it *abductor primus femoris*, and Winflow the *mufculus primus tricipitis*. It is the *pars octavi femoris* of Vefalius; that author, and indeed many others of the earlier anatomifts, not efteeming it a diftinct mufcle.

TRICOR, a name, by which fome of the chemical writers have called gold.

TRIDE, in the manege, fignifies fhort and fwift; thus a *Tride pace*, is a going of fhort and quick motions, tho' united and eafy. A *Tride career*, is a very faft gallop, with the times or motions fhort and nimble; and fo of other motions. Some apply the word only to the motion of the haunches.

TRIEDROSTYLA, in natural hiftory, the name of a genus of fpars.

The word is derived from the Greek τρεις, thrice, ἕδρα, a fide, and στυλος, a column.

The bodies of this genus are fpars, in form of trigonal columns, adhering by one end to fome folid body, and terminated at the other by a trigonal pyramid. Of this genus there are four known fpecies: 1. A flender one with a long obtufe pyramid: this is one of the moft common of all the the fpars, and is found in almoft all parts of the world; fometimes in fingle and large fpecimens, but more frequently in large congeries, coating over the fiffures of ftone in form of crufts. 2. One with fhort but pointed pyramids: this is common on Mendip hills, and is found in fome other parts of England. 3. A thick one with a longer pyramid, found in Northamptonfhire, and fome other parts of the kingdom, encrufting the fiffures of ftone. And 4. One with a very fhort column, and a long obtufe pyramid: this is frequent in the mines of Germany, and not lefs fo in thofe of England, particularly in Derbyfhire. *Hill's* Hift. of Foff. p. 222.

TRIEMERUS, the three-day fly, in natural hiftory, a fly fomewhat like the butterfly; it has four large yellowifh wings, and a long body, with a head furnifhed with long antennæ, large eyes, and a fpiral trunk. It is found among the nettles and mallows.

TRIENTALIS, in botany, the name of a genus of plants, the characters of which are thefe: The perianthium is compofed of fix leaves, and is permanent; the leaves are narrow, pointed, and wide expanded; the flower is of the ftellated kind, and is compofed of feven petals, which ftand flat and open, and adhere together very flightly at the top, thefe are a little longer than the leaves of the cup; the ftamina are feven capillary filaments, of the length of the cup, but inferted into the flower; the antheræ are fimple; the germen of the piftil is globular; the ftyle is capillary, and of the length of the ftamina; and the ftigma is headed; the fruit is a dry berry of a globular form, formed of an extremely thin cruft, and having only one cell; the feeds are few in number, and are of an angular figure; the receptacle is large enough to hold a great number of them; the number of the leaves of the cup fometimes varies. *Linnæi* Genera Plant. p. 187.

TRIERARCHI, τριηραρχοι, among the Athenians, commiffioners chofen annually out of the richeft citizens, who were obliged to provide all forts of neceffaries for the fleet, and to build fhips at their own charge. See *Potter*, Archæol. Græc. l. 1. c. 15. T. 1. p. 86.

TRIETERIS, τριετηρις, in the antient chronology, a cycle of three years. *Potter*, Archæol. Græc. T. 1. p. 459.

TRIEXAHÆDRIA, in natural hiftory, the name of a genus of fpars.

The word is derived of the Greek, τρις, thrice, ἕξ, fix, and ἕδρα, a fide.

The bodies of this genus, are perfect and pellucid cryftalliform fpars, confifting of thrice fix planes, being compofed of an hexangular column, terminated at each end by an hexangular pyramid: Of this genus there are three known fpecies. 1. A clear one with narrow and oblong pyramids: this is found in the mountains of Germany, and in North-Wales; but with us it is fmall and coarfe. 2. One with fhort pyramids and a long column: this is found in the mines at Goffelaer in Saxony. And, 3. One with fhort pyramids, and a thick and fhort column: this is found with us in the leadmines of Yorkfhire. *Hill's*, Hift of Foff. p. 204.

TRIFOLIUM *Trefoil*, in botany. See the article TREFOIL.

TRIFOLIUM *Paluftre*, *Buckbean.* This plant, tho' mentioned by feveral writers, before Simon Pauli, yet he was the firft who recommended it in fcorbutic cafes. He fays it is more fubtle and penetrating than *nafturtium* or creffes.

It feems at prefent to be coming into great repute in many chronical diftempers; and frequently prefcribed among alexipharmics.

Many have got it into ufe in their families in the form of tea, and experience its conftant ufe to be very effectual againft fcorphula's the king's evil, and obftinate fcorbutic diftempers. Its tafte at firft, is not very grateful, but time wears off that diflike; its ufe in fhop compofitions is not yet known. Vid. *Quinc.* Pharm. P. 2. Sect. 4. p. 124.

Buckbean ferves in Hampfhire to a very remarkable ufe; the brewers ufing it in their beer in the place of hops. It is as good a preferver of the drink, and is a bitter of as agreeable a flavour: it has this advantage alfo, that one eighth part of the quantity is fufficient, it is a very harmlefs plant, and is given by many as an antifcorbutic, and by fome in rheumatifms, and other chronic cafes. It might be extremely worth while to try this practice in other parts, as the plant might be eafily cultivated in any quantity, and that with this advantage, that it will grow on the worft kind of boggy land, that will produce nothing elfe. *Mortimer's* Hufbandry.

TRIFOLIUM *Acidum*, in botany, a name given by many authors to the oxys, or wood-forrel, from its having its leaves always three on a ftalk, and being of an acid tafte. See the article OXYS.

TRIFAX, among the Romans, a javelin three cubits long, which was thrown by the catapulta. *Pitifc.* in voc.

TRIGEMINI *Tertius*, in anatomy, a name given by Spigelius and others, to a mufcle called by Winflow the *complexus minor* or *maftoidæus lateralis*, and by Cowper and Albinus *trachelo-maftoidæus.* See the article MASTOIDÆUS.

TRIGLA, in the Linnæan fyftem of zoology, the name of a genus of fifhes, of the general order of the acanthopterygii: the diftinguifhing characters of thefe are, that the membrane of the gills has feven bones, and the pectoral fins have articulated appendages. Of this genus are the *lyra*, *hirundo*, *malvus*, *mullus barbatus*, &c. *Linnæi* Syftema Naturæ, p. 53. See the article LYRA, HIRUNDO, &c.

The characters of this genus, according to Artedi are thefe: The branchioftege membrane contains feveral bones; the head is very declivious, from the eyes to the end of the fnout, and is large, aculeated, and as it were fquare; the head is the broadeft part of the fifh, it thence grows gradually narrower, till it ends in a very fmall tail: in many of the fpecies of this fifh, there are two or three articulated appendices growing under the pectoral fins: the eyes ftand on the top of the head, and are covered with a fkin; there are two back fins, the firft of which is prickly; the pectoral fins in fome of the fpecies are very large.

Many of thefe fifhes are capable of making a noife; and fome of them by the help of their pectoral fins, can fuftain themfelves for a time out of the water, and fly to fome diftance. The appendices of the pylorus are from five to twenty.

Of thofe *Triglæ*, which have continuous, obtufe, and undivided fnouts, the following are the fpecies: The *Trigla* with a fmooth head, and with two fins on the lower jaw: this is the *mullus barbatus* of authors. 2. The *Trigla* with a fmooth head, with four yellow, not tranfverfe lines, on each fide, parallel to one another: this is the *mullus major*, or furmullet of our fifhermen. 3. The *Trigla* with a fmooth head and and without beards, all over of a red colour: this is called by authors the *mullus imberbis*, or king of the mullets. 4. The *Trigla* with the head fomewhat aculeated, and with a fingle little pinnule at the pectoral fins: this is the *milvus* of authors, or the kite-fifh; it flies four or five foot above the water, and that to a confiderable diftance. 5. The *Trigla* with a prickly head, and with three appendices on each fide at the pectoral fins: this is the *hirundo* of authors, and is called by our fifhermen the tub-fifh. Of thofe *Triglæ* which have the fnout a little forked, the following are the fpecies: 6. The *Trigla* with a fomewhat bifid fnout, and with the lateral line bifid at the tail: this is the *lucerna* of the Venetians, and the *milvus* of fome authors. 7. The red *Trigla*, with the fnout divided into two little horns, and with the opercula of the gills ftriated: this is the *cuculus*, and *lyra* of fome authors. This fifh grunts when taken out of the water, and the noife has been fuppofed to be like that of a cuckow, whence the name.

Of thofe *Triglæ*, which have the fnout very deeply divided, and opened into two very broad parts; the following are the fpecies: 1. The variegated *Trigla*, with the fnout divided into two prickles, and with two little prickles to each part: this is *gurnardus grifeus* of Ray, or the grey gurnard. 2. The *Trigla* with the fnout divided into two fpines, and with tubulous noftrils: this is the *lyra* of authors, called by our fifhermen the *piper*. 3. The *Trigla* with many cirri, and with an octangular body: this is the *lyra cornuta* of authors: the body is rendered angular, by having fix rows of acute and hard rhomboidal fcales. *Artedi*, Gen. Pifc. p. 32.

TRIGONAL-*Leaf*, among botanifts. See the article LEAF.

TRIGONELLA, in botany, the name of a genus of plants, including the fænugreek of authors; the characters are thefe: The perianthium is formed of one leaf, and is campanulated and lightly divided into five fegments, which are pointed, and nearly equal in fize; the corolla is papilionaceous, and feems compofed of three petals; the vexillum is oval, obtufe, and bent backwards; the two wings are of an oval oblong figure outwardly, by bending backwards, fo that in the vexillum, they feem to compofe a tripetalous flower of the common form; the carina is very fhort and obtufe, and occupies the middle of the flowers; the ftamina are diadelphous and fhort; the apices fimple; the germen of the piftil is of an oblong oval figure; the ftyle is fimple and erect, and the ftigma is fimple. The fruit is an oblong oval pod, of a compreffed figure, containing feveral roundifh feeds; the fhape of the flower alone, fufficiently diftinguifhes this from all the other genera of this clafs. *Linnæi* Gen. Plant. p. 362. *Tournef.* Inft. p. 270. *Rivin.* p. 497.

TRIGONELLA *Foffilis*, in natural hiftory, the name of a foffile fhell, of the cockle-kind, but approaching to a triangular figure, having a broad bottom to which it defcends, almoft in ftrait lines: on each fide from the head or cardo, thefe are ufually found fmall, but there are fome met with of four or five inches round: they are found at different depths, in ftone quarries, bedded in the matter of the ftrata; and that often in the hardeft ftone. In fome inftances, the fhells are found remaining in their native ftate; but moft frequently the fhell itfelf is perifhed and gone, and there is a ftony or fparry matter depofited in its place. *Hill's* Hift. of Foff. p. 646.

TRILL-*Hooks*, thoſe uſed to hold the ſides of a cart up to the horſe. See the article CART.

TRILLETTO, in the Italian muſic, a little ſhort ſhake or quaver; it differs from *trillo*, only in point of continuance being its diminutive. See the next article.

TRILLO, in the Italian muſic, is often found marked with a ſingle T; or tr, and often alſo by a ſmall t, as well in vocal as inſtrumental parts. It is deſigned to intimate, that you beat quick upon two notes in conjoint degrees, as *e f*, or *d e*, alternately; beginning with the higheſt, and ending with the loweſt. This makes what the French improperly call *cadence*, and properly *tremblement*. But it is alſo very often found in the Italian muſic to give notice, that the ſame ſound be ſtruck many times over, beginning a little ſlow, and ending with all the quickneſs, that the throat or finger can form them. Thus, ſuppoſing the firſt two or three quavers, then as many ſemi-quavers, and then ending with demi-ſemi-quavers, all in the ſame pitch or tune.

The manner wherein we have deſcribed this, comes far ſhort of what able maſters can ſhew in practice: This *Trillo* is more particularly uſed, after a note has been long held out, to eaſe the voice; which ſo long a tenſion had weakened. *Broſſard.*

TRILOBOUS-*Leaf*, among bontaniſts. See the article LEAF.

TRILOCULAR-*Capſule*, among botaniſts. See the article CAPSULE.

TRIMODIA, among the Romans, a bag like an inverted cone, in which ſowers carried their ſeed. It was ſuſpended from their necks, and was ſo called from its containing three buſhels. *Pitiſc.* Lex. Ant. in voc.

TRINGA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds, of the order of the ſcolopaces: the diſtinguiſhing characters of this is, that the feet have each four toes, and the beak is ſhorter than the toes. *Linnæi* Syſtema Naturæ, p. 47.

There are three ſpecies of this genus: The firſt called by almoſt all authors *Tringa*; the others the *pinirole*, and our *ſandpiper*. See the article SANDPIPER and PINIROLE.

The firſt ſpecies, or *Tringa*, moſt uſually ſo called, has been however named *cinclus*, by Bellonius; and *gallinula*, *rhodopus*, *phœnicopus*, and *ochropus*, by Geſner. It is ſomewhat larger than the black-bird, the colour of all its upper-ſide, is a very gloſſy greeniſh brown; and its ſhoulders and the ſmaller feathers of its wings are ſpotted with white. In the male, there are numerous white ſtreaks, and ſpots on the head, but in the female theſe are wanting; the throat is white ſpotted with black; the breaſt and belly are of a pure ſnow white; the long feathers of the wings are brown, and thoſe of the tail variegated with brown and white; its beak is a finger and half long, and of a greeniſh colour; and its legs of a bluiſh green; the hinder toe is very ſmall. They live about the ſides of ponds and lakes; its legs are ſometimes ſeen reddiſh or yellowiſh. *Aldrovand.* Tom. 3. p. 481.

TRINGA *Minor*, in zoology, a name by which ſome authors called the bird, commonly known in England, by the name of the ſandpiper. See the article SANDPIPER.

TRINITY (*Cycl.*)—By a ſtatute of king William the 3d, if one educated in, or having profeſſed, the chriſtian religion, ſhall be convicted in any of the courts of Weſtmiſter, &c. of denying any one of the perſons of the holy *Trinity* to be God, or maintaining that there are more gods than one, or of denying the truth of the chriſtian religion, or the divine authority of the ſcripture, he ſhall for the firſt offence be adjudged uncapable of any office; and for the ſecond diſabled to ſue any action, &c. Anno 9 and 10. *Will.* III. cap. 32.

TRINK, in our ſtatutes, is uſed for a fiſhing-net. 2 *Hen.* 6. c. 15. *Blount.*

TRIONUM, in botany, the name of a genus of plants, called by Ruppius *bammia*; the characters are theſe: The perianthium is double; the external one is compoſed of twelve ſlender leaves; the internal one is only compoſed of one leaf, and is inflated and divided into five ſegments at the end; the flower conſiſts of five petals, cordated at the top, and growing together at the bottom; the ſtamina are numerous, they grow into a cylinder at the bottom, and are free at the tops; the antheræ are kidney-ſhaped; the germen of the piſtil is roundiſh; the ſtyle is capillary and terminated, by five obtuſe reflex ſtigmata; the fruit is oval, but ribbed with five ridges, and is compoſed of five valves, and contains as many cells; the ſeeds are numerous and are kidney-ſhaped. It is plain from theſe characters, that this genus is nearly allied to the hibiſcus. *Linnæi* Gen. Plant. p. 383. *Ruppii* Flora Jenenſis, p. 16.

TRIOPHTHALMUS, a name given by authors to ſuch pieces of agate, or other ſemipellucid ſtones, as happen to have three ſmall circular ſpots, reſembling eyes upon them: theſe are of the nature of the common agate, &c. The ſpots are mere accidental varieties in the diſpoſitions of the veins, and do not make a diſtinct ſpecies of ſtone.

TRIOPTERIS, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is very ſmall and permanent, and is compoſed of one leaf divided into five ſegments; the flower is compoſed of ſix equal petals of an oval figure, and theſe are ſurrounded by three other ſmaller petals, which are alſo of an equal ſize one with another; the ſtamina are two filaments, beyond the petals of the flower, and are fixed to the cup; the external ones are ſomewhat ſhorter than the interior, and the antheræ are ſimple; the germen of the piſtil is divided into three parts; there are three erect and ſimple ſtyles; and the ſtigmata are obtuſe: there is no fruit to encloſe the ſeeds, but they ſtand naked, and are three in number, and are hollowed at the back, and edged with alæ, which when newly produced have the appearance of petals. Indeed what are called petals in this deſcription, are not ſo; but are the alæ of the germen, for the ſtamina are placed without them; but as they very much reſemble petals, a young botaniſt will more eaſily diſtinguiſh the genus, by their being taken for ſuch, than by any other means. *Linnæi* Gen. Plant. p. 195.

TRIORCHIS, a word uſed by ſome, to expreſs a man who has three teſticles.

It is alſo uſed as the name of a buzzard; and of a plant, called ladies traces.

TRIPENTAHÆDRIA, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek, τρὶς, thrice, πέντε, five, and ἕδρα, a ſide.

The bodies of this genus are ſpars, compoſed of thrice five planes; being made of a pentangular column, terminated at each end by a pentangular pyramid. Of this genus we only know one ſpecies; this has a moderately long column, and very ſhort and broad pyramids; it is found in Derbyſhire, Yorkſhire, and Cornwall, and is very frequent about Goſſelaer in Saxony. *Hill's*, Hiſt. of Foſſ. p. 205.

TRIPHARMACUM, an ointment, in the late London diſpenſatory, ſo called from its being compoſed of three ingredients: the preſcription is this: Take common plaſter four ounces, oil olive two ounces, vinegar one ounce; ſet them over a gentle fire, and ſtir them continually, till they become an ointment. *Pemberton's*, Lond. Diſpenſ. p. 370.

TRIPOLI, (*Cycl.*) in natural hiſtory, the name of an earthy ſubſtance, uſed by the lapidaries to poliſh ſtones, and by the braſiers, and other the like artiſts to clean metalline veſſels. It is of two kinds, the yellowiſh, and reddiſh white; the yellowiſh white kind is called by authors, *alana gleba*, *tripolis* and *terra tripolitana*; this is the produce of Germany, Saxony, and France; there is alſo of it in the neighbourhood of Venice, but it is found in greateſt plenty in many parts of Africa. It is found a dry hard earth, of a very pale yellowiſh white, of a firm texture, and moderately heavy; it is ſometimes found of itſelf, conſtituting a ſtratum; but is more frequently met with in detached pieces among ſtrata of other matter. It is of a rough, irregular, duſty ſurface; it adheres ſlightly to the tongue, is dry, hard, and harſh to the touch, is not to be broken between the fingers, and ſlightly ſtains the hands: it makes no efferveſcence with aqua fortis, and makes a ſlight hiſſing noiſe on being thrown into water. The reddiſh *Tripoli* is of our own production, though not peculiar to ourſelves; it is found in great abundance on Mendip-hills in Somerſetſhire, nor leſs plentifully in many parts of Germany. This is well known in the ſhops as a ſubſtance of great uſe in poliſhing braſs, but is not applied to any of the other uſes of the yellowiſh kind: this like the former is moſt frequently found in detached maſſes, and while in the earth is tolerably ſoft, and eaſily falls into flakes. When dry it becomes of a conſiderable hardneſs, and is of a fine pale reddiſh white, of a looſe open texture, compoſed of a multitude of extremely thin plates or flakes laid evenly on one another, and conſiderably heavy; it is of a ſmooth and ſomewhat gloſſy ſurface; it adheres very firmly to the tongue, is dry and harſh to the touch, too hard to be broken between the fingers, and does not ſtain the hands: it makes no efferveſcence with acids, and burns to a paler colour, with ſome additional hardneſs. *Hill's*, Hiſt. of Foſſ. p. 68.

TRIPUDIUM, in antiquity, a ſpecies of divination, in which omens were drawn from the rebounding of corn thrown to chickens. *Hofm.* Lex. Univ. in Voc.

TRIPYRAMIDES, in natural hiſtory, the name of a genus of ſpars.

The word is derived from the Greek τρὶς, thrice, and πυραμὶς, a pyramid.

The bodies of this genus are ſpars, compoſed of ſingle pyramids, each of three ſides, ſtanding on no column, but affixed by their baſes to ſome ſolid body.

Of this genus there are only two known ſpecies: 1. A ſhort and thick one, found on the ſides of the ſtacks of ſtone in Northamptonſhire and elſewhere; but this is not common, and is uſually ſmall. 2. A long one with a narrow baſe: this is not found in England, but is common in the German mines. *Hill's*, Hiſt. of Foſſ. p. 226.

TRISACTIS, in natural hiſtory, a name of a genus of ſtar-fiſh, compoſed of a body and three rays, the more uſual number being five. See the article STELLA *Marina*.

TRIQUETRA *Oſſa*, triangular bones found in ſome craniums.

TRIQUETRUM *Folium*, among botaniſts. See the article LEAF.

TRISCÆDECACTIS, in natural hiſtory, a name given by Linkius, and ſome other authors, to a kind of branched ſtar-fiſh

fiſh or aſtrophyte; whoſe rays are thirteen in number, where they firſt leave the body, and each divides into many more.

TRIS-DIAPASON, *Triple-Diapaſon*, in muſic, what is otherwiſe called a *Triple eighth*.

TRISE, at ſea, the ſeamen's word, for haling up any thing with a dead rope, or one that doth not run in a block, but is pulled by hand or by main ſtrength: thus if any caſk, cheſt, or other goods hath only a rope faſtened to it, and ſo without a tackle be pulled up into a ſhip by hand, they ſay it is *triſed up*.

TRISETÆ, the *three-haired* flies, a term uſed by the writers in natural hiſtory, to expreſs a certain genus of the ſeticaudæ, or briſtle-tailed flies, which are diſtinguiſhed from the reſt, by having three hairs or briſtles growing from the tail: there are ſeveral kinds of theſe flies, found frequently among our hedges.

TRISEUS, in ichthyology, a name given by Salvian, Benedictus Jovius, and others, to that ſpecies of the gadi, which we call the eelpout, and authors in general the *muſtela fluviatilis*.

TRISPERMUM, in pharmacy, the name of a cataplaſm or pultice, conſiſting of three ingredients, theſe are cummin, and opium ſeed, and bay-berries.

TRISSA, in zoology, a name uſed by ſome authors, for the fiſh more commonly known by the name of alauſa, and called in Engliſh *ſhad*, or the mother of herring. *Rondelet*. de Piſc. p. 21. See the articles ALAUSA, and AGONUS.

TRISTO, a word uſed by Paracelſus, to expreſs what he calls the material fire; lodged in the matter of all the four elements, and exerting upon occaſion its influence, under the form of the proper effects of each element.

TRITÆOPHYES, a word uſed by the medical writers of the antients, to expreſs a kind of fever, much of the nature of the tertian, and taking its riſe from it.

TRITE (*Cycl.*) — This chord of the antient tetrachord, was ſo named from its being the third from the nete; and hence we might call it the anti-penultimate. It was otherwiſe in ſome tetrachords called parypate. See the articles PARYPATE, DIAGRAM, and NETE.

TRITE *Diezeugmenon*, in the Greek muſic, was the anti-penultimate note of the diezeugmenon tetrachord, and anſwers to Guido's c, ſol, fa, ut. *Wallis*, Append. *Ptolem*. Harm. p. 157. See the article DIAGRAM.

TRITE *Hyperbolæon*, in the Greek muſic, was the anti-penultimate note of the hyperbolæon tetrachord, and anſwers to Guido's f, fa, ut. *Wallis*, Append. *Ptolem*. Harm. p. 157. See the article DIAGRAM.

TRITE *Synemenon*, in the Greek muſic, was the anti-penultimate note of the ſynemenon tetrachord; and anſwers to Guido's b, fa. *Wallis*, Append. *Ptolem*. Harm. p. 157. See the article DIAGRAM.

TRITHEITÆ, in church hiſtory, a name given to ſuch heretics, as admit not only of three perſons, but of three diſtinct ſubſtances and natures, in the holy Trinity. See the article TRINITY, and TRITHEISM, *Cycl*.

TRITICUM, *Wheat*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, the diſtinguiſhing character of which is, that the calyx is a glume containing ſeveral flowers, compoſed of two valves, and containing the flowers arranged into a ſhort ſpike; the valves are of an oval figure, and obtuſe; the flower is bivalve and of the ſize of the cup; the valves are nearly of the ſame ſize, and the exterior is bellied, obtuſe and pointed, and the interior ſmooth and flat; the ſtamina are three capillary filaments; the antheræ are oblong and ſplit at the ends; the germen of the piſtil is of a turbinated form; the ſtyles are two, capillary, and reflex; the ſtigmata are plumoſe; the flower incloſes the ſeed till ripe, and then opens and lets it out; the ſeed is ſingle, oval, and oblong, obtuſe at both ends, and convex on one ſide, and marked with a deep furrow on the other. Whatever plant has all theſe characters, whether the grain be eatable or not, is properly a wheat. *Linnæi* Genera Plantarum, p. 16.

TRITON *Avis*, in zoology, a name under which Nieremberg has deſcribed a bird of the Weſt-Indies, famous for its fine ſinging, and found in Hiſpaniola; it is ſaid to have three different notes, and to be able to give breath to ſounds of all three kinds at the ſame time; it is alſo ſaid to be a very beautiful bird. *Ray*'s Ornithol. p. 299.

TRITOPATORIA, τριτοπατορια, in antiquity, a ſolemnity in which it was uſual to pray for children, to the Θεοι γενεθλιοι, or *god's of generation*, who were ſometimes called τριτοπατορες. *Potter*, Archæol. Græc. T. 1. p. 434.

TRITTYARCHI, τριττυαρχοι, among the Athenians, were magiſtrates who had the command or government of the third part of a tribe. *Potter*, Archæol. Græc. T. 1. p. 78. See the article PHYLARCHUS.

TRITURATION, (*Cycl.*)—Mr. Lindern relates two obſervations, which contradict the doctrine of violent *Trituration*, ſaid to be performed by the ſtomach in digeſtion. 1. A dog having ſwallowed a die, vomited it up again eleven or twelve hours after, when the bony part of the die was much diminiſhed, but the pins of wood, on which the ſpots are marked, were entire, and ſtood out a conſiderable way from the bone. 2. Three ſtomachs of ſwine, were cruſted ſo thick over their interior ſurface with a ſtony ſubſtance, that all their cavity was filled, except a canal in the middle, of about an inch diameter. Notwithſtanding this, the fleſh of the creature was fair and ſound, and ſold well. Hiſt. de L' Acad. des Sciences. 1732.

TRIUMFETTA, in botany, the name of a genus of plants, the characters of which are theſe: There is no cup unleſs the flower itſelf be called ſo; this conſiſts of five ſtrait erect concave petals, obtuſe at the ends and bending backwards, and have a prominent point within the leaf, below the apex; theſe fall ſoon after they open, whence they appear rather the petals of a flower, than the leaves of a cup; the ſtamina are ſixteen erect ſubulated filaments, of equal height and of the length of the flower; the antheræ are ſimple; the germen of the piſtil is roundiſh; the ſtyle is ſimple, and of the length of the ſtamina; and the ſtigma is bifid and acute; the fruit is a globular capſule, every way beſet with crooked prickles, and containing within it four cells, in each of which are two ſeeds, convex on one ſide, and angular on the other. It is very rarely, however, that more than one ſeed comes to maturity in the ſame cell. *Linnæi* Genera Plant. p. 243. *Plumier*, Gen. 8.

TROADENSE *Marmor*, a name given by the antients, to a ſpecies of white marble, dug in mount Ida, and greatly uſed in building.

TROCHILUS, (*Cycl.*)—TROCHILUS, in zoology, a name uſed by Ariſtotle, Pliny, and others of the antient naturaliſts, for the *regulus criſtatus*, or, as we call it, the golden-crowned wren. *Ray*'s Ornithol. p. 163. See REGULUS.

TROCHILUS is alſo the name of a remarkable water-bird, being very long-legged, yet web-footed.

It is a very ſwift runner on the ground, and is thence called by the Spaniards *corriza*. Its beak is ſtrait and black at the end, and the opening of its mouth very wide; it has black eyes, ſurrounded by a white naked membrane, and that by a brown one. On its under part it is white; its back, ſhoulders, and wings, are of a ferrugineous colour; its running is ſo very ſwift as to equal the flight of moſt birds. *Aldrovand*, de Avib. l. 19. c. 35.

TROCHISCI *e Nitro*, a form of medicine, preſcribed in the late London diſpenſatory, the preparation is thus: Take purified nitre four ounces, fine ſugar a pound, reduce them to fine powder, and make them up into *Troches*, with mucilage of gum tragacanth. *Pemberton*'s Lond. Diſp. p. 323.

TROCHISCI *e Sulphure*, a form of medicine, preſcribed in the late London pharmacopœia, and made in this manner: Take of flower of ſulphur waſhed two ounces, of double refined ſugar four ounces; beat them together, and by gradually adding mucilage of quince-ſeeds, form *Troches*. *Pemberton*'s Lond. Diſp. p. 324.

TROCHITÆ (*Cycl.*)—Theſe ſingle joints of the entrochus are found in ſome places in ſuch vaſt numbers, as to make people ſuſpect that they could never have been ſo ſtrangely collected together, if they ever had been of animal origin; but this is one of the many too raſh concluſions of the modern naturaliſts.

If we conſider the vaſt number of arms or branches, of which the ſtar-fiſh conſiſts, whence theſe are produced, it will not a little tend to ſolve the difficulty: but if after this we conſider the manner of life of the animal, we ſhall find yet more reaſon to be ſatisfied, that the number of theſe foſſils is no argument againſt their being its remains. The ſpecies of ſtar-fiſh, whence they have their origin, is famous for the immenſe, and indeed amazing, number of its arms; each of theſe arms is compoſed of an immenſe number of theſe ſingle joints, and the creatures while living uſually herd together; and it frequently happens that in graſping after their prey, an arm or limb breaks off; the conſequence of this is, that wherever the mutilated limb touches the arm of another fiſh of the ſame kind with its truncated end, it adheres and grows to it, ſo as never to be ſeparated again: thus the two fiſh are for ever faſtened together. As they are continually reaching out their arms in ſearch of prey, this accident often happens among them; and it is not unuſual to find a cluſter, of twenty or more, of them thus growing together, and with their expanded arms forming a ſort of net. Now if it be conſidered, what a large number of ſingle joints or *Trochitæ*, go to the formation of the thicker part of one arm; and how immenſe a number of arms, ſuch a cluſter as this poſſeſſes, from ſo many fiſh, each furniſhed with ſo large a number, we ſhall find, that the dis-united joints of one ſuch cluſter as this, ſcattered over a ſtratum of clay, would appear an amazing number: how much more then, the produce of twenty, fifty, or a hundred ſuch, which it is no wonderful thing ſhould be found in one place, ſince they are gregarious animals.

The compariſon of a ſingle *Trochite*, or entrochus, with the arm of this recent ſtar-fiſh, will at once evince the truth of this account of their origin, and the great error of thoſe who have ſuppoſed them of a vegetable nature, and called them rock-plants. *Kepellus*, Epiſt. de Entroch. See the article ENTROCHI.

TROCHITIFER *Glans*. See the article GLANS *Trochitifer*.

TROCHLEARIS (*Cycl.*) in anatomy, a name given by Fabricius, and fome other writers, to one of the mufcles of the eye, called by Albinus the *obliquus fuperior oculi*; and by fome, from its office, the *opifex circumgyrationis oculi*.

TROCHUS, in natural hiftory, the name given by authors to a genus of fhells; fome of the fpecies of which refemble the figure of the *Trochus*, or top, which boys play with. As there are many fpecies of this fhell, however, which are flatted and have nothing of this form, the whole feries of them are much better named, by a denomination taken from the fhape of the mouth, which is of an oval figure, and is alike in all thefe fpecies, and different from all other fhells. They are therefore aptly charactered by a late French writer under the name of *cochleæ ore depreffo*. See the article COCHLEA.

TROCTUS, in ichthyology, a name given by Ariftotle, Ælian, Atheneus, and others of the Greek writers, to the fifh called *amia* by Pliny, and moft other of the later as well as antient Latin writers; but by fome, *lechia* and *glaucus*. It is properly a fpecies of the fcomber, and is diftinguifhed from the others by the name of the fcomber with two fins on the back, and with the laft ray of the hinder fin very long. This is an obvious character, by which it is eafily diftinguifhed from all the other fcombri, of which it is a genuine fpecies. See the article SCOMBER.

TROGLODYTES, in the Linnæan fyftem of zoology, the name of a diftinct genus of birds, of the order of the pafferes; the diftinguifhing character of which is, that the beak is thread-like and pointed, and is crooked, and longer than the head. *Linnæi* Syftema Naturæ, p. 49. See the article PASSER.

TROIS *Cinque*, in the French diftillery, a term ufed to exprefs their brandy when of a peculiar ftrength, confifting of five parts alcohol, and three parts phlegm.

The method of diftilling the wines into brandy in France, is exactly the fame with that ufed with us to draw the fpirit from our wafh or fermented liquor of malt, treacle, fugar, or whatever other kind. They only obferve more particularly to throw a little of the natural lee into the ftill, along with the wine; and the pooreft wines are found to fucceed beft on the trial, making by much the fineft brandies. We are apt to wonder, that we cannot from the wines of particular countries diftil their particular brandies; but the whole myftery confifts in this, that they do not fend us over the fame wines which they ufe in diftilling, becaufe thefe latter would not be liked as wines, nor would keep in the bringing over. Sometimes in Scotland, they meet with the poor and prick'd wines, the fame that the French diftil their brandies from; and from thefe they diftil a fpirit, not to be known from the brandy diftilled in France.

The lee, which the French add in the diftillation, gives the brandy that high flavour, for which we fo much efteem it; but they themfelves like it much the worfe for it. The French notion of a proof ftrength, determined by the chapelet or crown of bubbles, is the fame with ours; and all their fine fpirits are found of this ftrength.

But they have one particular expedient for thofe brandies, which prove foul and feedy, or retain the tafte of certain weeds which grow among the wines; they draw them over again, with a defign to free them from that adventitious flavour. In this operation they always leave out the faints, or rather they change the receiver as foon as ever the ftream comes proof; then mixing together all that run off before, they make a brandy ftronger than the ordinary kind, and this is what they call *Trois-cinque*.

The diftillers in France fcarce ever bring their brandies higher than this; for they have the art to perfuade the foreign merchant, that the phlegm of French brandy is natural and effential to it: but the truth is, that the fpirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and fent over in the ftate of alcohol, and then lowered with common water, to the proof ftrength.

The French ufe no art in colouring their *Trois-cinque*, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour. The thing which they principally value themfelves upon, both in regard to brandies and wines, being to make them perfectly natural: fo that all the colour we find in their brandies, is acquired from the cafk, and the time they are left in it. This is often twelve or eighteen months, fometimes two or three years; in this time they acquire a brown colour, and lofe their acrid tafte.

The greateft adulteration of brandies is in England; the French have no temptation to do it, they having no cheaper fpirit, fince the prohibition of molaffes in their country. The Dutch are in the fame condition, having no molaffes fpirit; and only a very coarfe and naufeous fugar-fpirit, and a yet worfe malt fpirit of their own manufacture; a fingle gallon of which, would fpoil a whole piece of brandy. The French brandy alfo paying no duty in Holland, is as cheap, or nearly fo, there as in France itfelf. The duties being high upon brandy in England, it is greatly adulterated, and that with all forts of fpirits; as malt, melaffes, cyder, and fugar fpirits; and when this is done in a dexterous and fparing manner, the cheat is not eafily found out. *Shaw*'s Effay on Diftillery.

TROMBA, in the Italian mufic, either denotes the common trumpet, the buccina of the antients, or the modern facbut, but more properly our trumpet. See the articles TRUMPET, SACBUT, and BUCCINA, *Cycl.*

TROMBETTA, in ichthyology, a name given by the Italians to the fifh commonly called *fcolopax* by authors. See the article SCOLOPAX.

It is properly a fpecies of the baliftes, and is diftinguifhed by Artedi, by the name of the baliftes with two fpines in the place of the belly-fins, and another fingle fpine below the anus. See the article BALISTES.

TROMBETTA, in the Italian mufic, a fmall trumpet, being the diminutive of *tromba*. See the article TROMBA.

TROMBONE, in the Italian mufic, a facbut. See the article SACBUT, *Cycl.*

TROMBONE, *picciolo*, *groffo*, *primo*, *fecundo*, &c. See the article SACBUT. Ibid.

TROMPE, in the manege. See the article DECEIVED.

TRONCO *per Grazia*, in the Italian mufic, by the French called *coup de grace*; is ufed to intimate to the voices, as well as inftruments, that they are not to draw out the found to its natural length, but cut it fhort; that is, only continue it long enough to be heard, by which means there is a fmall filence between each found; which has a very good effect in expreffions of grief, to make figns; and alfo in expreffions of wonder and furprife, *&c.*

TRONE (*Cycl.*)—TRONE-*Pound*, in Scotland, contains twenty Scotch ounces. But becaufe it is ufual to allow one to the fcore, the *Trone-pound* is commonly 21 ounces.

TRONE-*Stone*, in Scotland, according to Sir John Skene, contains $19\frac{1}{2}$ pounds. Vid. Treat. Pract. Geom. p. 153.

TROOPER, in the military art, a private man in a troop of horfe.

TROPER, in our old writers, is ufed for a book of alternate turns and refponfes in finging mafs. *Lindewode* calls it *liber fequentiarum*. *Hoved.* Hift. p. 283.

TROPHY (*Cycl.*)—TROPHY, in architecture, an ornament which reprefents the trunk of a tree, charged or encompaffed all round about with arms or military weapons, both offenfive and defenfive.

TROPIC (*Cycl.*)—TROPIC-*Winds*. Dr. Lifter has advanced a very ftrange fyftem as to the nature and origin of thefe, which is, that they are owing to the halitus of fea-plants, growing in great abundance in particular places; he fuppofes that the Levant breezes are brifkeft about noon, becaufe the fun at that time exhales moft from the plant. The direction of this breeze from eaft to weft, he fuppofes may be partly owing to the general current of the fea; for a gentle air will be led by the ftream of our rivers, for example; and partly to this, that every plant is in fome meafure an heliotrope or turnfole, bending itfelf in fome degree after the fun, and confequently emitting its vapours according to the courfe of the fun. Phil. Tranf. N°. 156. See the article TROPICAL, *Cycl.*

TROSSULI, among the Romans, a name given by fome to the guards that attended the kings of Rome, otherwife called *Celeres*. See the article CELERES.

TROUSSEQUEUE, in the manege. See the article DOCK.

TROUT, (*Cycl.*) a very valuable river-fifh, the diftinguifhing characters of which are thefe: Its body is long; its head fhort and roundifh; the end of its nofe or fnout obtufe and blunt; its tail is very broad; its mouth large; and each jaw furnifhed with one row of fharp teeth; and in its palate there are three parcels of teeth, each of an oblong figure in the congeries, and all meeting in an angle near the end of the nofe; and the tongue has fix, eight, or ten teeth alfo on it; and its fides are beautifully variegated with red fpots.

This delicious fifh is obferved to come in; and go out of feafon with the ftag and buck; the time of its fpawning is remarkable; moft other fifh do this in warm weather, but the *Trout* in October or November. Among the feveral kinds of *Trout*, the red and the yellow are the beft for the table; and in the fame fpecies the female has always the preference to the male; the head of the female is fmaller, and the body deeper than in the male. They are known to be in feafon by the bright colour of their fpots, and by the largenefs and thicknefs of their backs; which laft is a general rule in regard to all fifh, to know when they are in feafon.

In the winter the *Trout* is fick, lean, and unwholefome, and very often is loufy. The loufe, as it is called, of the *Trout* is a fmall worm with a large head, which fticks very faft to the fides of the fifh; they live upon the juices of the fifh all the time of the cold weather, while he is poor and lies quiet in the deep waters; but when the warm weather in the fpring comes on, and the fifh leaves his lazy life at the bottom, and comes up to the fhallow gravelly places, where the ftream is fwift, he foon fhakes them off.

The *Trout*, at its firft coming into the fhallow waters, may be feen to rub his body continually upon the fharp gravel at the bottom; it is by this means that he gets off thefe worms or

or lice, as they are called. From this time he begins to feed on flies; but in May the peculiar fly that he is fond of is produced, and after feeding that whole month on this insect, the flesh of the fish becomes more red and firm, and its highest season begins.

The general baits for a *Trout*, are a worm, a minnow, or a fly, whether natural or artificial: among worms there are several kinds which this fish is fond of; such are the earth-worm, and dung-worm in particular; the lob-worm and branding-worm also are esteemed: but the best of all is the squirrel-tail worm, which has a streak down the back, a red head, and a broad tail. The brandling is commonly found in a old dung-hill, or under cow-dung, or else among tanners-bark; the others are found in the earth, and under large stones or stumps of trees: whatever worm is used, the longer it is kept to scower first, the better the *Trout* will take it: they are to be kept in an earthen-pot among moss, which is to be shifted once in three or four days, or oftner if the weather be very hot.

To take the *Trout* with a ground-bait, the angler should have a light, taper, rod, with a tender hazel top; and may angle with a single hair of three links, the one tied to the other, for the bottom of the line; and a line of three haired-links for the upper part: with this sort of tackle, if the sportsman have room enough, he will take the largest *Trout* in the river. Some fish with three haired-links at the bottom of the line, but there is very little sport to be expected this way, for the *Trout* is very suspicious and very quick sighted. The angler must always keep out of sight, and the point of the rod must be down the stream. The season for fishing for the *Trout* with a ground-bait begins in March, and the mornings and evenings in general are the best time; but if the weather be cloudy, the sport may be followed all day long. There must be a plummet at ten inches from the hook, which the angler must feel always touching the ground, and this must be heavier the swifter the stream is. The common worm is a good bait.

The minnow is a very good bait for the *Trout*, and with this the tackle need not be so slight, for the *Trout* will make at this bait with less consideration, and sieze it as soon as it comes in sight; the upper part of the line with this bait, may be of three silks and three hairs for the upper part, and two silks and two hairs for the lower; and the hook may be moderately large. The whitest minnows and those of the middle size are the best bait for the *Trout*, and they should be so fixed on the hook, as to turn round when they are drawn up against the stream. The best way of baiting this fish, is to put the hook in at the mouth and out at the gills, then drawing it thro' about three inches, to put it again in its mouth, and let the point and beard come out at the tail, and then to tie the hook and his tail with a fine white thread, letting the body of the minnow be almost strait down the hook; by this means it will turn, as it is pulled against the stream; and the more and quicker it turns the better: for want of a minnow, a small loach or a stickle-back will serve.

The most agreeable manner of fishing for *Trout* is, however, with the fly, when the sportsman has found the true method of doing it; the rod in this case must be light and pliable, and the line long and fine; if one hair be strong enough, as it may be made, by proper skill in the angler, there will be more fish caught, than where a thicker line is used; and the fly-fisher should have the wind in his back, and the sun before him.

TRUFFLES, (*Cycl.*) *Tubera*, in botany. See the article TUBERA.

The antients, it is evident from their writings, were not acquainted with the sort of *Truffles* which we have in use at present; they describe theirs to have been of a reddish colour, and smooth on the surface; we at present know this kind very well; it is common in Italy, and is called the wild *Truffle*, and disregarded. They had indeed the white African *Truffle*, sometimes brought to them, and held it in vast esteem for its flavour. The Romans called it the Lybian *tuber*, and the Greeks the Cyrenean *misy*; these people were very little acquainted with the African affairs, and called all the things they had from that part of the world by the name of Cyrenean.

Avisenna recommends those *Truffles* as the best which were of a whitish colour within; and this not being a clear white, he expresses himself by a word which signifies sand-coloured, alluding to dusky white sand, in common use at that time. Pliny has so far mistaken the sense of the author from whom he takes his accounts, that he says, the Lybian *tubera* or Cyrenean misy were more fleshy than the others: but Theophrastus says only, that they had a rich flesh-like smell, by which he distinguishes them from the insipid *Truffle* in common use with the Greeks at that time. The word *ramul* which the interpreters of Avisenna have rendered sand-coloured, may be perhaps properly *ramad*, which is ash-coloured; and if this be the true reading, we get over a great many difficulties, among the later writers about what the tubera arenosa or sandy *Truffles* of the antients were.

It is certain that the finest *Truffles* were called by some authors by this epithet *arenosa*, with a very different meaning, only expressing that they were produced in sandy countries: the European *Truffles* both then were, and now are mostly produced in dry ground on the sides of hills; but the Lybian were produced only in the burning sands of that country, and these were therefore called sand-*Truffles*. Serapio tells us, that the best of all *Truffles* were those produced in sand; and Martial alludes to these, where he describes the finest *Truffles* as breaking the surface of the earth into cracks, and by that means directing people where to search for them. This passage of Martial has been indeed severely criticised on by many; and our own observation, and the testimony of Pliny called in to prove the poet in an error: we do not indeed see the ground burst or crack where the *Truffles* are; and Pliny tells us expresly, that the *Truffles* of his time never broke the earth where they grew, but remained quietly under it without giving any indication of their being there. This may all be true both of the common Roman *Truffle* and of ours; but as Martial here plainly speaks of the finest kind, that is the Lybian *Truffles*, we must see whether the African *Truffles* do or do not break the ground where they lie, before we censure or applaud the poet. Leo Africanus is the most express in the account of the Lybian-*Truffle* of any author, and he says, that the places where they are may always be known by the earth on the surface being raised into hillocks, and breaking in numerous cracks: thus we find the poet is so far from being culpable in his expression, that he appears to have been better acquainted with the nature of the subject, than the author who wrote expresly upon it.

The *Truffle* is most abundantly produced in dry fields of a reddish loamy earth, not too poor; and they are found to flourish most near the roots of elms, the ilex, and some other trees. They do not well bear the severity of hard winters, but are usually scarce all the season after such. The smallest are found about the bigness of a pear, and they grow from this size sometimes to a pound weight, but such are not common; what are taken up in the spring are distinguished by their white colour, and insipidity to the taste, and are commonly called white *Truffles*: those taken up in autumn are of a variegated colour within, and are called marbled *Truffles*; the inner substance having swelled extreamly and changed colour, and the white part now remaining only in form of a number of pipes or tubules, which seem in many places to run to the extremity, and terminate in the chaps and wrinkles of the back. The greyish substance, which is wrapped up among these tubules, when examined by the microscope, appears to be a transparent parenchyma, composed of little bladders or hollow vessels, in the midst of which may be seen small round bodies, which are unquestionably the seeds of the *Truffle*.

When the *Truffles* are arrived at this degree of maturity, which is generally in August, they are of a fine high flavour and agreeable smell; and the heat and rains at this season greatly promoting their growth, has been the occasion of the old error, that thunder produced them; after this they continue good to the middle of winter, and sometimes even till March; but those gathered from this time till the end of July are small and only white, never marbled nor of their high taste.

If the *Truffles* are not taken up when fully ripe, they always rot and burst; whence it is plain that they are an annual plant, which lives no longer than till they have perfected their seeds. And if the place where the old ones have rotted and burst be examined, the seeds will be found after some time to have vegetated, and a great number of young *Truffles* to be produced in the place: these, if not destroyed by the frosts, are what in the ensuing spring furnish the younger white *Truffles*.

The *Truffle* is very apt to be pierced and eaten within by a worm, and this tho' a damage to the particular *Truffle*, is of some service to the people, who make it their business to seek for them: for this worm, after a proper time passed in that state, changes into its chrysalis state in the body of the *Truffle*; whence he soon after comes out, in the shape of a beautiful violet-coloured fly; and wherever these flies are found, they are an indication that there are beds of *Truffles* near, as they are never bred in any other root.

These communicate a bitterness to the whole *Truffle*, and and make it unfit for the table; tho', if the whole be carefully searched into, the part eaten by the worm, and the hole by which it made its way in, will be found to be in reality the only bitter parts, and the rest of the *Truffle*, when these are cut out, as good as ever: but, beside these destroyers, the microscope usually discovers on the surface of the *Truffle* a multitude of other devourers, which are small white animalcules, continually eating, and searching the cracks of the bark, as the places where the pulp is most easily come at; these somewhat resemble mites.

The earth that produces *Truffles* rarely affords any other plants, these taking up all the nourishment it can afford: the earth all about them smells so very strongly of them, that they are easily found out by it, by the animals which carry their noses near the ground: and those who fought after them

soon

foon found the way of ufing hogs to fearch them out; but thefe being a fort of unmanageable animal, dogs were found, which would fupply their place with more certainty, and much lefs trouble. Mem. Acad. Scien. Paris, An. 1711.

TRUFFLE-*Worms*, in natural hiftory, a fpecies of fly-worm which is found in *Truffles*, and lives in and feeds on them, till the time it undergoes the common metamorphofis of thefe creatures, for the production of a fly, like that from the egg of which it was hatched.

Thefe are a great nufance to the *Truffles*, and often wholly fpoil them: on preffing them in this ftate with the finger, one may ufually perceive fome places give way, and on opening thefe the worms are found.

They are very fmall, and have two brown fpots, eafily diftinguifhable near their hinder end; which are the two pofterior ftigmata. They are all over white, and very tranfparent; and one may very eafily diftinguifh the two black ftalks of their two hooks, with which they tear the fubftance of the *Truffle*, as the other fpecies do their food: the anus in thefe is very vifible, and is placed near the extremity, and under the belly; the creature fecretes from this a whitifh vifcid matter, which is a great means of haftening the corrupting of the *Truffle*: while in the *Truffle*, thefe worms are always furrounded with this vifcid matter; but when they have arrived at their full growth, which is ufually in a few days, they then leave the *Truffle*, and go to feek fome proper place, where they may reft during the time of their transformation; they enter the earth for this purpofe, and twelve hours after they have gone into it they are transformed into an egg-fhaped fhell, of a chefnut-brown, of the fame fort with that of the blue flefh-fly.

This fhell is in thefe, as in all the other infects of the fame clafs, made of their proper fkin; what it has particular is, that it is fomewhat flatted, efpecially at the anterior end; and all the way down this flatted part, on each fide, it is bordered by a fort of band or filament, like that on each fide at the anterior end of the fhells of the common flefh-fly worm.

The ftigmata are placed in a line with thefe, and the anterior ones terminate them; at the middle of the anterior end, there are feveral folds, like a purfe when drawn together, which encompafs the opening by which the firft ring is drawn in at the time of the formation of this fhell.

Thefe are the worms in a manner peculiar to the *Truffles*; but befide thefe, they often furnifh nourifhment to another fpecies, very common in mufhrooms of the ordinary eatable kind, and which has a yellow body and a black cruftaceous head. *Reaumur's* Hift. Inf. Vol. 4. p. 374.

TRUMPE, in ichthyology, a name given by fome of the Englifh writers, to that fpecies of whale, called by the generality of authors *cete*, and *balæna major*.

It is, according to the new fyftem of Artedi, one of the catodons; and is diftinguifhed from the other fpecies of that genus, by having the fiftula fituated in the neck: the Dutch call this the pot whale-fifh. See the articles CATODON, and BALÆNA.

TRUMPET (*Cycl*)—TRUMPET-*Flower*, *Bignonia*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is compofed of only one leaf, of a tubular form, wide open at the mouth; and feeming as if bilabiated: from the flower-cup arifes a piftil, which is fixed in the manner of a nail to the hinder part of the flower; this afterwards becomes a fruit or pod, divided into two cells by a longitudinal membrane, and containing flatted and ufually alated feeds.

The fpecies of *Bignonia* enumerated by Mr. Tournefort are thefe: 1. The afh-leaved American *Bignonia*, with great fcarlet-flowers. 2. The afh-leaved tree-*Bignonia* of America, with yellow flowers. 3. The fhort-podded American *Bignonia*, with tendrils to the ftalks. 4. The long-podded American *Bignonia*, with long tendrils to the ftalks. 5. The two-leaved climbing American *Bignonia*, with long and broad pods, and broad feeds. 6. The bifoliate-climbing American *Bignonia*, with fweet-fcented, violet-coloured flowers, and dry, oval fruit. 7. The bifoliate-climbing American *Bignonia*, with purplifh-yellow, fcentlefs flowers, and hard, oval fruit. 8. The tree-*Bignonia* of America, with thin box-like leaves. 9. The tree-*Bignonia* of America, with fingle undulated-leaves, and very long and narrow pods. 10. The heart-leaved tree-*Bignonia*, of the Eaft-Indies. 11. The long-leaved Indian tree-*Bignonia*. 12. The five-leaved Indian tree-*Bignonia*, with a rofe-coloured flower, and flat pods. 13. The fmaller five-leaved Indian tree-*Bignonia*, with a rofe-coloured flower, and angular pods. *Tourn.* Inft. p. 164.

TRUMPET-*Shell*, *Buccinum*, in natural hiftory, the name of a large genus of fhells, the characters of which are thefe; they are univalve fhells of the form of a *Trumpet*, according to old pictures; with a wide belly, and a large, broad, and elongated mouth. They have a diftinct and regular tail, ufually long, tho' fometimes fhort; they have a crooked beak, and the clavicle is often elevated, tho' fometimes depreffed and contabulated. See Tab. of Foffils, Clafs 9.

The family of the *Buccina*, when examined ever fo ftrictly, is very large; but according to the general cuftom of authors, of confounding together feveral genera under the name, it is ufually made to appear much larger than it really is. *Lifter* has made it comprehend a vaft number of fhells, by confounding with it the families of the *murex* and *purpura*.

It is not indeed peculiar to this author, to have confounded thefe genera; thofe who went before him have done the fame: and Pliny has comprifed the *buccinum*, *murex*, and *purpura*, under the general name *ceryx*.

To avoid the general confufion, which arifes from not diftinguifhing the families of the *buccinum*, *murex*, *purpura*, and *vis*, or fcrew-fhell, it will be proper to obferve, that there are regular characters, which diftinguifh them all, one from another: the characters are thefe:

The *buccinum* differs from the *purpura*, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the *purpura* has a round mouth, and a head fomewhat flatted. The tail of the *purpura* is alfo ufually furrowed, and is fhorter than that of the *buccinums*.

The *buccinum* differs alfo from the *murex* in having a longer tail, by the fmoothnefs and variety of colours of its coat, and by having a larger mouth lefs furnifhed with teeth; the *murex* having a fmaller and longer-fhaped mouth, its furface covered with points or fpires, and feveral teeth.

It is eafier to diftinguifh the *Buccinum* from the fcrew-fhell, as this is always more long and flender than the *buccinum*; it has alfo a flat mouth, and has rarely any tail. Thefe are all very large families in nature, and it is highly neceffary for the naturalifts to be well acquainted with them.

The moft fingular fpecies of the *buccinum* clafs, is one that has its mouth turned the contrary way to all other fhells: this has been thence called by authors, the *unique* and the *fans pareille*. Aldrovand is of opinion, that the *buccina* may be ranked among the bivalve fhells; becaufe they have an operculum, or fhelly fubftance, fixed to the end of their body, which occafionally ftops up the aperture of the mouth; but if this were a fufficient reafon we fhould have many more genera to add to the bivalves, particularly the fnails of feveral kinds.

The *buccina* generate in the warm months, and fome fpecies of them are feen very frequently remaining in pairs together, upon the rocks deferted by the tide on that occafion. Thefe have been thence fuppofed to be of a different genus, and have been called *buccina littoralia*; they are ufually found in copulation early in the morning. *Rumphius*, de Teft. *Aldrovand*. de Teft. l. 3. c. 231. *Lifter*, Hift. Animal. Angl. p. 158.

The fpecies of the *buccina* being very numerous, they are arranged under feveral diftinct heads, according to certain obvious diftinctions; and are as follow: 1. Of the *buccina* with long diftinct tails and oblong mouths, there are thefe fpecies. 1. The great brownifh white, contubulated, and tuberous *buccinum*. 2. The fmall brown furrowed *buccinum*. 3. The *buccinum* with double and dentated lips. 4. The *buccinum* called the tower of Babel. 5. The red-fpotted *buccinum*. 6. The Perfian *buccinum*. 7. The radiated *buccinum*, with broad, blackifh-red fpots. 8. The *buccinum* fafciated and undulated on each fide, with a dentated columella. 9. The thick *buccinum*, with oblong and fpotted tubercles. 10. The ftriated and bottle *buccinum*. It is to be obferved that when the laft fpecies but one is polifhed, the lofs of its outer coat gives it a very different appearance; and it is found in many of the cabinets of the curious, variegated with blue and whitifh-brown fpots. 11. The *buccinum*, with a contabulated and pulvinated clavicle. 12. The ftriated *buccinum*, with three tuberous eminences. 13. The coftated and ftriated *buccinum*.

Of the *buccina* with a fhort tail and a wide mouth, we have the following known fpecimens: 1. The hairy *buccinum* of Rumphius. 2. The thick *buccinum* called Midas's ear, with a dentated columella: this when polifhed affumes a very different appearance, and is found in many cabinets under the name of the agate *buccinum*, as it carries a great refemblance of that ftone. 3. The grey wide mouth *buccinum*: this alfo when polifhed affumes a very different appearance, and is fpotted and lineated in an elegant manner; tho' wholly plain while it has its outer coat. 4. The undulated and ftriated *buccinum*. 5. The *buccinum* covered with pointed tubercles placed in regular order. 6. The depreffed umbilicated *buccinum*, with the lip and columella both dentated. 7. The yellow umbilicated *buccinum*. 8. The *fans pareil*, or *buccinum* with the mouth opening the contrary way to all the other. 9. The alated and punctuated *buccinum*. 10. The tuberous *buccinum*, with two high ribs. 11. The rough furrowed *buccinum*, with a thick lip and an oval mouth. 12. The hermit *buccinum*: this ufually has the hermit-fifh, a kind of fmall crab in it, and has its clavicle full of fmall balani.

Of the *buccina* which have long and erect clavicles, thefe are the following known fpecies: 1. The Chinefe town fhell, with a dentated columella. 2. The *buccinum* furrounded with red and white fafciæ. 3. The *buccinum* called tiara or papal crown, with the columella and lip dentated. 4. The mitre or plume *buccinum*. 5. The yellowifh *buccinum*, with a dentated columella. 6. The *buccinum* with zones of brown and yellow. 7. The great triton *buccinum*. 8. The wide mouthed

mouthed *buccinum*. 9. The ftriated *buccinum* with prickly ribs. 10. The reticulated *buccinum*, with oblong tubercles. 11. The red-mouthed fpotted *buccinum*, with an irregularly ftriated clavicle.

Of thofe *buccina* which have lefs erect clavicles and crooked roftra, there are the following known fpecies: 1. The rough *buccinum*, called the Swifs-fhell. 2. The diftortion or grimace fhell, with a ftriated lip and columella. 3. The *buccinum* with its lip elevated above the reft of the furface. 4. The fmooth-lipped *buccinum*. 5. The fmoother bodied *buccinum*: thefe are all of the grimace kind. 6. The rough *buccinum*, with elevated tubes or pipes. 7. The tuberous *buccinum*, with a dentated wide mouth, and a long crooked and furrowed roftrum. 8. The yellowifh tuberous ftriated *buccinum*, with a depreffed clavicle, and with furrowed lips and columella. 9. The yellow *buccinum*, with an erect clavicle and a red mouth. 10. The ftriated *buccinum*, with oblong tubercles. 11. The ftriated gold-yellow *buccinum*. 12. The *buccinum* with brown, yellow, and white ftriæ. Hift. Nat. Eclair. p. 263.

It appears from the writings of the antients, that the famous purple dye, which they obtained from a fhell-fifh was not peculiar to any one fpecies; but was found in feveral of the fmaller kinds of *buccina*; fome of which they called *murices*, from the hollow fpines, or long and flender proceffes, which run in different directions from their fhells.

Mr. Reaumur when on the coafts of Poitou, found certain eggs of fifhes, arranged in regular order, and in great numbers, on the rocks and falted banks, which had the fame property with the purple-dying liquor of the *buccinum*; and which, as it is not yet known to what particular fifh they belong, or what ufes they may hereafter be brought to ferve, it may be proper to defcribe here.

Each egg is of an elliptic fpheroidal figure, the fmalleft part of which is about a twelfth of an inch in diameter, and the largeft about one fifth, and it is attached to the rock or fand by a pedicle refembling that of a fruit; this is about a twelfth of an inch long, and a fourth part of its length in diameter. The egg itfelf is hollow, and is filled with the ftaining liquor; its furface is only a membrane in the nature of parchment: at the end, oppofite to that where the pedicle is fixed, there is a hole or aperture, refembling the mouth of a glafs-bottle; but that the liquor may not run out at this, it is ftopped with a tranfparent fubftance, which ferves as a cork to it; this however is placed exactly in a contrary direction to the corks of our bottles; for the larger end is on the infide, fo that all the force the included liquor can have on it, can be only to ftop up the mouth the more firmly: befide this alfo, it is cemented down all round by a fort of glue. This egg contains two liquors, the one white and the other yellow; as the common eggs have their yolk and white: but the yellow liquor in this, is not collected all into one body; but fwims about freely in the white in eight diftinct drops. The glutinous liquor by which the pedicles of thefe eggs are faftened to the ftone or fand, is of fuch force, that it is not eafy to pull them off without breaking the eggs; but by help of the thin blade of a knife, they may be taken off without injury. As there are always a great number of the *buccinas* of the fmaller kinds, about the places where thefe eggs are found, Mr. Reaumur was led to believe that they were the eggs of this fifh; in favour of which fuppofition, the colour they afford in common with that fifh, is alfo no fmall argument; what made this opinion appear lefs probable to him, was the largenefs of thefe eggs in proportion to thofe animals; but we are fo well affured of the largenefs of many fhell-fifhes eggs, in proportion to their own fize, that this feems but a weak argument againft fo probable an opinion. Mem. Acad. Par. 1711.

Pliny feems to derive the name *buccinum* from *buccina*, a kind of mufical inftrument [a]; but it is more probable that inftrument took its name from the fhell to which it bore a refemblance, and of which it might probably have been antiently made [b].—[[a] *Plin*. Hift. Nat. l. 9. c. 36. [b] Phil. Tranf. N°. 282. p. 1277.]

Buccina are of fome ufe in phyfic; when calcined they have a drying cauftic quality. *Lifter*, Ap. Phil. Tranf. N°. 197. p. 645. See Tab. of Shells, N°. 9. and Tab. of Foffils, Clafs 9.

Buccinum lapidofum is a figured ftone, fhaped like the former, and probably only a petrifaction of the fhell above-mentioned. *Mercat*. Metalloth. Arm. 9. loc. 36. c. 33. p. 301.

Ray fpeaks of a *buccinum* which not only petrified, but after petrifaction was converted into a pyrites. *Ray*, Phil. Lett. p. 202. See PYRITES, *Cycl.* and *Suppl.*

TRUMPETER, (*Cycl.*) in zoology, a name given in England, to a particular fpecies of pigeon, called by Moore the *columba tibicen*.

This fpecies is of the middle fize of the common pigeon, and made confiderably like it; but it is pearly-eyed; is of a mottled black, and is feathered down the legs and feet, and is turn-crowned like the nun, and fome of the other fpecies; fometimes like the finnikin, but much larger: this feems to be the beft fort as being the moft melodious. The beft character to know them by, is a tuft of feathers growing at the root of the beak; and the larger this tuft is, the more they are efteemed. The reafon of their name is, that they imitate in their cooing the found of the trumpet; but to be often entertained with their melody, it is neceffary to feed them frequently with hemp-feed. *Moore*'s Columbarium, p. 45.

TRUMPETER, in a man of war, one whofe office is always to attend the captain's command, and be ready at the entertainment of ftrangers. In the time of an engagement his proper ftation is on the poop.

TRUNGIBIN, in natural hiftory, a name given by Rawwolf, Tournefort, and others; to a fort of manna collected from the *albagi maurorum*, as the common manna is from the afh; and ufed in the eaftern parts of the world as a purge. It is what we call the *manna perficum*, and tho' in itfelf a very fine and clean kind of manna, yet it is ufually fo carelefly collected, and mixed with fo much filth, that it requires to be given in three times the dofe of ours, in order to purge. The name feems very evidently to be a corruption of the *tereniabin* or *teren-jabin* of the Arabians, which was the word ufed by all their authors to exprefs the *manna perficum*.

TRUNCATED *Leaf*, among botanifts. See the article LEAF.

TRUNK, (*Cycl.*) in natural hiftory, a pointed, hollow, flender, and oblong body; joined to the fore-part of the heads of many infects, and ferving them for fucking the blood or juices of the animals or vegetables, on which they feed.

The *Trunks* of flies ferve for diftinguifhing many genera of thofe little animals, from their different form and other accidents. Some of thefe are a tube formed all of one fimple piece, and others compofed of feveral fhorter pieces, nicely joined together: fome are thin and as it were fhelly, others thick and flefhy; thofe of fome flies are terminated by a fort of broad foot, or by a fort of thick lips; and thofe of others have no lips, or at leaft no fenfible ones; and others are made in form of a fpindle hollowed at the end.

It is often neceffary to have recourfe to the microfcope, to diftinguifh with nicety and exactnefs between thefe; and how indeed is it poffible to do any thing without the help of glaffes, in the diftinctions of the parts of animals, the whole bodies of which are fo very minute.

Without the affiftance of glaffes, however, it is eafy to diftinguifh among the flies of different genera, three different manners of carrying this organ when in a ftate of inaction. Many flies have *Trunks* which they can fhorten, when they are not ufing them; thefe are fixed in the fore-part of the creature's head, where there is a cavity deftined to receive them when they are not in ufe. In many fpecies, this cavity is no more than a mere finus or hole, in the fore-part of the head; but in others it is more nicely contrived, the anterior part of the head lengthening itfelf, and forming a kind of arched vault for its reception. Other flies have *Trunks*, which in the time of inaction are turned, or fomewhat folded from above downwards; the *Trunks* of bees are of this kind. Ibid.

There are others alfo, which have their *Trunks* contained entirely in a fort of cafe, where they lie ftrait at length, without being either turned or folded; but they are able to encline them in any direction, in regard to the pofition of their legs: of this kind are the *Trunks* of the cicadæ, gnats, &c.

Among the butterfly clafs, a great number are furnifhed with a *Trunk*; but there are alfo a great number that have it not: the fly of the filk-worm, and many, as well larger as fmaller kinds, are without this, (as it feems neceffary) organ, by which they fuck the juices from flowers; and which is the only way of their taking in nourifhment. Thofe fpecies which have it, fhew it to the firft view; it is placed in the middle of the head directly between the two eyes. And tho' in feveral fpecies it is very long, yet it takes up even in thefe but very little room; when it is not in ufe, it is always rolled up in a fpiral form, in the manner of the fpring of a watch; and even the fhorteft of them are thus turned as well as the longeft. Some of them make only one or two turns of this kind, others of a middling length make four; and finally the longeft of all frequently make eight turns. In the rolled ftate, we can fee only a fmall part of one of the outer turns of the fpiral; the origin and extremity, with a great part of the intermediate fpires, being hid under a remarkable fort of hood or mitre; which is formed of two hairy bodies, following the contour of the eyes, and arifing from their under-part in form of pieces of the fkin of fome animal, with the hair upon it. Thefe are moveable at the pleafure of the animal, and feem intended by nature only as a cafe, for the defence of this tender and neceffary organ to the creature. *Reaumur*, Hift. Inf. vol. 1. P. 1. p. 287.

This is the cafe in moft of the fpecies, but in fome others the office of thefe hairy bodies is fupplied by two rounded and very prominent parts, which in the fame manner follow the contour of the lower part of the eyes, and fill up a great part of the front of the head; leaving only a fort of channel or furrow between them as a place for the *Trunk*. Thefe parts the French naturalifts call the beards of the butterflies, and in fome fpecies they are of a very fingular figure; extremely different from thofe which have been here defcribed. If one is defirous to know in what manner this *Trunk* is ufed, he need only follow a butterfly to a flower, and there obferve its motions. As foon as it is fettled on the verge, it unrols

rols this *Trunk*, and extends it into a perfectly ftrait piece; it then directs it into the flower, and thrufts its extremity to the very bottom, where it is affixed to the cup; this is the cafe, however deep the flower be. When it has been a few minutes in the flower, it draws it out and rolls it up; and after a few moments, it extends and plunges it into the flower again: this it repeats four or five times, and then flies away to another flower. This is the thing that has occafioned the poets to make the butterfly the emblem of inconftancy, in its flying immediately from one flower to another; but the truth is, that the flower it leaves is no longer capable of affording it the nourifhment it wants.

There are among the butterflies, fome which never fettle upon any thing, but are eternally upon the wing in the manner of fwallows: thefe feed on the wing as thofe birds do. We often fee them buzzing about a flower in the manner of a bee, and in that cafe they fuftain themfelves in the air with their wings, while they unrol their *Trunk*, and thruft its extremity into the flower, to fuck from its bottom the honey-dew, which is the common food of them, of the bees, and of many other infects.

The *Trunk* of the butterfly is a flat body, being broader than it is thick, and is formed of a matter fomewhat refembling horn; if the head of the creature be fqueezed, it becomes neceffitated to unrol the *Trunk*, and may thus at any time be made to fhew it at its length. Its origin is juft in that part of its face, where the nofe in other animals takes its origin; and hence fome authors who have obferved it when unrolled, have called thofe butterflies which are poffeffed of it the long-nofed ones; but this is very improper, as it affuredly fupplies the place of a mouth. It is always largeft at the infertion, and thence gradually decreafes to a point at the other end.

The *Trunk* of the butterfly may alfo be unrolled, by getting the point of a pin between the circles at the center, and then drawing it gently from the head, the *Trunk* will by this means be drawn out to its full length; and if we tieze the creature a little, by gently preffing any part of it, it immediately opens a crack, in the middle of which it runs up by degrees to the origin or bafe, and fplits it in a manner into two.

It has been much difputed, among the curious obfervers of nature; whether the *Trunk* be originally compofed of two parts, or two *Trunks* laid clofe to one another; or whether it were owing to its tender ftructure, that it was eafily fplit by breaking its parts.

Mr. Bonani was of the firft opinion, and Mr. Riget agreed with him at firft, but he afterwards became of the contrary fentiment; and thought that they really broke in this fplitting, being originally only one: but Reaumur has determined the queftion in favour of Bonani; having, by repeated obfervations, found them compofed of two parallel *Trunks*, nicely and evenly laid fidewife together. This indefatigable fearcher after truth, examined the *Trunk* in the butterfly, while yet in its cryfalis, and when juft iffuing from it: he obferves that, in the firft cafe, the *Trunk* is not rolled up, but is laid evenly lengthwife along the body, and in this ftate it is eafily feen to be made up of two parallel *Trunks*; but in the fucceeding ftate, of juft hatching from the cryfalis, one may fee that it is compofed of two: for one of the firft efforts of the creature, is to roll this organ up into its fpiral form, and in doing this, the two pieces often gape fo wide afunder, and are rolled up fo irregularly, that it is fcarce to be conceived how the animal will be able to lay them even afterwards. This however is done by feveral times rolling and unrolling it; they join firft regularly at the bafe, and then by degrees all the way along to the point. It fometimes happens that there are difficulties in this, and the parts become folded, wrinkled, or otherwife injured in their figure; and if all this be not fet right in a few minutes, by the action of rolling and extending it; it never is done afterwards, but the organ dries in that form, and the creature lofes the whole ufe of it, and is doomed foon to perifh by hunger. Mr. Ray mentions a butterfly with a double *Trunk*; but Mr. Reaumur never having been able to find any fuch, it is very probable, that as Mr. Ray was unacquainted with this ftructure of the *Trunks* of all thefe creatures, he only found one whofe *Trunk* had never clofed. *Reaumur*, Hift. Inf. vol. 1. P. 1. p. 293.

The union of the two parts, of which the *Trunk* in thefe creatures is formed, is too ftreight to be owing merely to their contact; were they no better joined, they would frequently open and feparate, in the frequent rolling and unrolling of the whole, for the taking in of food. It is evident, on the contrary, that they are faftened together by a nice joining, and a very vifcous fluid.

There are among the *Trunks* of butterflies, only two fuch effential differences, as to deferve a general diftinction; the one kind of thefe are longer, flatter, and rolled up into more fpirals; the others are fhorter, thicker, and make fewer turns. The firft refemble a fort of thin blades, the others refemble a cord; fome of the flat ones are two or three inches long, and thick in proportion: thefe are the propereft for a microfcopic obfervation, in order to know their true ftructure; and when examined in this manner, they are found to be formed in an elegant manner, and made up of fibres, which divide themfelves into a number of rings, and refemble the annular ftructure of the *afpera arteria* in large anninals. Some of the *Trunks* of thefe animals are bright and gloffy, both on the under and upper fide; and fome of them have a number of fmall flat bodies iffuing from them which are ufually placed at the extremity, tho' fometimes at a diftance from it; thefe have been fuppofed by fome, to be a fort of fingers, whofe ufe was to collect together the nourifhment fit to be received into the *Trunk*; and others have fuppofed them the organs of fuction: but they appear rather to be only intended by nature, as fupports to the end of the *Trunk* while employed in fucking, as they have no organization proper for anfwering either of the other purpofes affigned to them, and as they are obferved only in the more weak and tender *Trunks*, the ftrong and thick ones having none of them. The two bodies which form the *Trunk* of the butterfly, have each of them a hollow running all the way along them, or are each of them properly a feparate canal, capable of receiving a fluid and conveying it up into the body of the animal. *Reaumur*, Hift. Inf. vol. 1. P. 1. p. 301.

Mr. Reaumur found out their ftructure with great eafe, by moiftening or foaking them in water after the creature was dead: after this treatment they became much more manageable and pliant than before, and could be rolled and unrolled at pleafure, and cut tranfverfely or in any other direction. The matter of which thefe *Trunks* are formed feems more of the nature of whalebone, than of any other known fubftance; and, like that, if thus fuppled by foaking in water, they are in fome degree tranfparent, from the thinnefs of their fides; and when they have been long enough in water, if they are preffed with the finger, there may be feen a feparate column of water moving about in each. And as this obfervation is moft eafily made on fuch *Trunks* as have been cut off tranfverfely from the head, thefe receiving the water the moft readily, the whole may in thefe be at pleafure preffed out at the ends where they are cut; and the joining of the two canals, or parts of the *Trunk*, along the middle, is more like that of the feathered part of a bird's plume, than any other combination in the parts of the animal world; and the joining of the two parts is fo nice, that there is another or third canal formed by it, which is nearly as clofe at the fides as the other two: this may ferve the creature for the conveying its food as well as the other two, but it appears more probable that its office is to convey the air for the creature's refpiration, and that the *Trunk* in this manner ferves in the office both of a mouth and a nofe.

The other kind of *Trunks* of the butterfly clafs, are the fhort and thick ones; thefe are not flat, but rounded like a cord; they are very robuft and ftrong, and they terminate in a fharp point, which in fome fpecies is capable of wounding the finger if preffed againft it: in all, however, it is capable of wounding and making its way into the tender fubftance of the leaf of a flower. The manner of the creature's getting its nourifhment is this: it plunges the end of the *Trunk* into the fubftance of the flower, by means of the hole made by this fharp end, fo far, that its apertures are in the place where the juices extravafate themfelves, from the wound the point has made; the point itfelf being often on the other fide, having pierced quite through. When it has thus drained away all the juice it can, it flies to another flower, and acts in the fame manner. There is a fpecies of butterfly, remarkable for having a fort of a figure of a death's head on its breaft; this fpecies has a thick *Trunk* of this kind, fo very fharp at the point, that it is capable of wounding the hand.

The action of the *Trunk* in fucking is eafily feen on giving a piece of fugar to a butterfly, that has been kept without food for fome days, after its being produced out of the cryfalis; many of the fpecies will in this cafe feed on the fugar in the fame manner that they would on the juices of flowers, and will fhew that the ufe of their rolling up their *Trunk* at times, is the fwallowing what they have received into it. The *Trunks* of the feveral fpecies of butterflies are as different in colour as in fhape; fome are black, others reddifh, many of a chefnut colour; fome are alfo of a pale brown, and fome of a beautiful yellow; many of them alfo are hairy on the under fide, and many are fmooth. The thicker *Trunks* are always fhorter than the flat ones, and have only one canal. *Reaumur*, Hift. Inf. Vol. 1. P. 1. p. 309.

TRUNKS *of Gnats*, the inftrument by means of which, the gnat ftrikes the flefh, and fucks the blood from animal bodies.

This is a machine well worth an attentive obfervation. As fine and fmall as this inftrument appears, it is neverthelefs of a very complex ftructure. The piercer, or more properly piercers of this inftrument, are all entirely hid in the fheath which makes what we call the *Trunk*; and is the only part we naturally have offered to our view. *Reaumur*, Hift. Inf. Vol. 4. p. 580. feq.

This *Trunk* appears to be cylindric, in the greateft part of its length; and is covered with fcales, not unlike thofe on the nerves of the wings of the creature; and refembling fmall leaves. Near its end, it has a little fwelling, where there is an oblong button, broader at its infertion than at its point: the end of this button is furnifhed with an aperture, out of which the creature occafionally thrufts a fine point. Many naturalifts have obferved this point; Swammerdam confidered it

it as a single pointed body, formed to pierce the skin; but Lewenhoek discovered that it was made up of a vast number of pointed bodies. There is no occasion, however, for all the accuracy of observation of Swammerdam, nor all the power of the magnifying glasses of Lewenhoek, to discover that this is a complex body; a common small magnifying-glass, and a careful examination, will at any time discover it.

If a gnat be held by the corcelet between the fingers, and a little squeezed, the sheath or case of the *Trunk* will be frequently seen to open itself lengthways on each side, sometimes only a little way, and at others almost along its whole length; and a fine glossy reddish filament shews itself at the opening of this case. This filament is bent and turned inwards, and one very soon distinguishes that it is indeed a congeries of a great number of filaments: these one may easily separate, in some measure, from one another, by means of any pointed instrument; and very often the filament separates of itself into several in the bending. It is plain, therefore, that the instrument destined to pierce the skin, and suck the blood, is of a complex structure; that what we might naturally take for this instrument, is only its case or sheath, and that this case, instead of a plain cylindric body, is really a composition of two semi-cylindric ones, which have the power of separating from one another for the animal's occasions.

The best way to get a regular sight of the *Trunk* of this creature, and of its manner of using it, is to suffer a gnat to settle upon the hand, and not disturb him in the operation; but with a magnifying glass in the other hand, to observe all his motions. In this case, we may first see a small and slender point thrust out at the end of the case, and try several different parts of the skin with this sharp instrument; when it has done this, it chooses that part which is most easily pierced; and where there lies a vessel underneath, capable of furnishing as much blood as he will have occasion to suck.

As soon as he has made his choice, the wound is immediately given; and since the point of the compound piercer cannot be protruded so far out of the case as it is necessary it should to strike to a proper depth, the use of the slit in this case is seen; for while the button at the end of this remains firmly applied to the orifice of the wound, where the piercer is introduced, and supports that delicate and feeble instrument from bending, the case opens at the slit, and its two sides bend to give room to the piercer to penetrate; and at length, when the piercer is sunk to its utmost depth, the two extremities of each piece touch, and the sides are brought close together.

Sometimes also one may observe in peculiar species of the gnat kind, when they are about to strike the flesh, a more complex structure of this sheath; for one may see, instead of the two antennæ which all the gnats have, an appearance of four, while the creature is in the act of sucking. It will be easy for any one to guess, that the second pair of these, which do not appear at any time, except when the creature is thus employed, are not true antennæ; and on a nice examination, they appear indeed to be no other than parts of the case of the piercers, which, as soon as the gnat of this species strikes the skin, are separated from the upper part of the case, and are two slender oblong bodies, of the same length with the case, except that part of it which we call the button. These two pieces of the cases at this time stand always in a parallel direction with the true antennæ, and are very nearly of their length. Each of these, examined in this state, has the appearance of a regular cylinder, but, probably, in its state of rest, is hollowed, and of a proper shape, to enclose and surround a part of the surface of the case; and this must of necessity be their real shape, since when the *Trunk* is in a state of rest, they are no other way distinguishable on it, than by the making it a little thicker; whereas, were they really cylindric bodies, as they appear in the state of action of the *Trunk*, they must, when it was at rest, be seen in form of two prominent lines on its surface.

The several species of gnats have great variety in their *Trunks*; and in the observing many kinds, the true structure of that organ in all will be most regularly and easily found. Some have the case of the piercers only one single tube split lengthwise along its upper part; others have this slit made by the junction of two cases, which cover closely a great part of its circumference; and others have the two tubes so well adjusted, and nicely fitted to one another, that a good glass cannot discover them from the rest of the *Trunk*, when in a state of rest; but in others this structure is easily discoverable, as the extremity of one of them, when best fixed, is still to be discovered somewhat separated from the *Trunk*, and adorned with a pencil of small hairs, like those of the antennæ. The male gnats, which have their antennæ feathered, are those which have the plumes at the extremities of these additional pieces of the case of the *Trunk*; and these have not the beards which are found situated over the *Trunks* of the other species of gnats.

There is, beside all these, one species of gnat whose piercer has no need of the button at the end of the case, common to all the rest, to support it while it enters the flesh. This has a case on which it rests itself as on a seventh leg, from which it darts a piercer, which, without any support, is of sufficient strength to penetrate the flesh, and do its office for the animal. This species of gnat has two very long beards placed above its *Trunk*, and terminated by an end, covered with white scales; what remains of these beards is covered with brown scales, and the body of the gnat is brown, and the corcelet reddish.

Tho' it is easy to find that the *Trunk* of a gnat is composed of several pieces, yet it is by no means easy to say what the number of them is. The best microscopes often shew the whole a single body, its several parts are so extremely well joined; and when they have been found to be more than one, it is very difficult yet to say how many they are. Lewenhoek imagined them to be four in number; and Swammerdam, who had first believed the whole a single filament, afterwards thought he discovered six pieces going to its composition.

After separating the piercer of the gnat wholly from its sheath, if it be cut transversely near its base or insertion in the head, and the section laid upon the plate of a microscope, and there touched with an extremely fine pointed instrument, it may be divided into four, and sometimes into five separate pieces. Two of these may often be seen to come out of a third, as out of a canal or tube: the seeming necessity of a tube in this instrument, for the sucking the blood, has made many ready to persuade themselves that they have seen one: but if we follow the analogy of nature in her other works, we shall find there is no absolute necessity for such an organization in this part; since, in the gad fly, the several pieces of which the piercer is composed are of themselves able to form a tube for the passage of the blood.

The figures of the several constituent parts of this instrument are as difficult to be determined as their number; thus much is certain, however, that the points of all the pieces are by no means alike, for some are much longer than others.

Out of the immense number of gnats that one sees in summer, in wet places, it is easy to determine that very few have any chance, even once in their lives, to suck the blood of larger animals. The rest, however, are far from being doom'd to perpetual famine; the herbs of the field afford them a sufficient nourishment; for these, like many other of the insect tribes, are partly carnivorous, partly otherwise, and feed equally on flesh and vegetables. *Reaumur*, Hist. Insect. vol. 4. p. 580. seq.

TRUNK-*Manna*. See the article MANNA.

TRUNSCHIBIL, a word used by Tournefort, to express the manna Persicum, called also by some *Trungibin*; both evidently corruptions of the terenjabin of the Arabians. See the article TRUNGIBIN.

TRUSSED, in the manege. A horse is said to be *well trussed*, in French *bien gigoté*, when his thighs are large and proportioned to the roundness of the croupe. On the contrary, a horse with thin thighs, that bear no proportion to the breadth of the croupe, is said to be *ill trussed*.

TRUTTACEOUS, in zoology, the name of a genus of fishes of the trout kind, which are distinguished from all other fishes by a small fat fin, which they all have near the extremity of the back, and which has no rays or nerves. Of the fish of this genus, some live only in fresh waters, never entring the sea or salt rivers: others frequent both the fresh and salt waters, and are therefore called *anadromi* or *catanadromi*. These leave the fresh waters while young, and go into the salt waters to feed and grow, and again return into the fresh rivers at the time of their full growth and spawning, that their offspring may have the same advantages themselves have had, of being hatched into life in fresh water.

The *truttaceous* fishes are divided into two orders, those which have, and those which have not teeth. Of the edentulous kind, or such as have no teeth, are the lavaretus, ferra, thymallus, oxyrynchus, and albula; and of the toothed kind, are the salmo, umbra, trutta, carpio, &c. In dissection, the *truttaceous* fishes have all apophyses to the pylorus, and are all a high-tasted and fine set of fish for the table. *Ray*'s Ichthyography, p. 182.

TRY (*Cycl.*)—TRY, at sea. A ship is said to *try*, when she has no sails but her main-sail aboard; when her tacks are close aboard, the bowlings set up, and the sheets haled close aft; when also the helm is tied close down to the board, and so she is let lie in the sea. And sometimes when it blows so hard that they cannot maintain the main-sail, as they say, that is, cannot bear it out, they make her lie a *Try* under a missen-sail only.

TRYBLION, a word used by the old medical writers, to express the pot or dish in which the medicines used in fumigations were placed at the time of use.

TRYCHNUS, in botany, the same as *Strychnus*, the name of the nightshade. The Greeks called it στρύχνος, and the Latins, as well as themselves, often left out the initial σ, as they do in many other words; thus they write *milax* for *smilax*, *maragdus* for *smaragdus*, &c.

Pliny uses the word *Trychnos* as the proper name of the plant; and Dioscorides, willing to distinguish the mad nightshade from the sleepy nightshade, which are the two poisonous kinds, so called from their different effects, calls the one *Trychnos* and the other *Strychnos*. But this is a trivial difference in the name, and would never be esteemed any difference

ference by thofe who know the Greek language, in which this is familiarly done without any intent of diftinguifhing.

Theocritus mentions the plant *Trychnus*; but he is to be underftood of a third kind, differing from both thefe poifonous ones, and bearing an efculent fruit. This was the plant we now call *lycoperficon*, or *pomum amoris*. The writings of Theophraftus warrant the poet in calling this plant, as well as the others, by the common name *ftrychnus*, or *Trychnus*; for he exprefsly fays, there are three kinds of *Trychnus*, one which caufes fleep, another which caufes madnefs, both poifonous, and a third, which is efculent.

The *poma amoris* are at this time eaten by the Jews with us, and by ourfelves in foups, and the like. The Italians, Spaniards, and Portuguefe, all eat them, and efteem them a very delicate difh. The later Greek writers have left off the ufe of the word *ftrychnus*, and ufe the term *melintzanion* for this plant. See the article MELINTZANIUM.

TRYGUM, in ichthyology, the Greek name given by Elian, Athenæus, and Appian, to the fifh which we call the *paftinacha marina*, or fire-flaire. Ariftotle and fome others write it *tragum*. The fifh is a fpecies of the ray, and is accurately diftinguifhed by Artedi by the name of the fmooth-bodied ray, with no fin on the tail, and with a long fpine ferrated on the anterior parts. See the article RAJA.

TRYING, in pharmacy, the purifying fat fubftances, by means of melting, and feparating them from their membranes, &c. In the college difpenfatory, the method laid down for the purifying lard, fuet, &c. is this: Melt them at a gentle fire, with the addition of a little water intermixed, and, when melted, ftrain them from the membranes. The addition of water in this keeps the fat from burning and becoming black, which it would otherwife do; for the water, not being capable of receiving any greater degree of heat than that of boiling, will keep the bottom of the veffel from growing too hot, much better than the niceft management of the fire could do. *Pemberton*'s Lond. Difp. p. 146.

TSAPHARI, in the materia medica of the antients, a name given by fome to the cadmia, called by Diofcorides, *placitis*, and by others of the Greek writers, *zonitis* and *onychitis*. It was a flat kind, forming a fort of coat or cruft on the walls or fides of the furnace: hence it had the name *placitis* or *cruftaceous*; and it was called *onychitis* and *zonitis*, becaufe, when broken tranfverfely, it appeared made up of feveral fucceffive plates, which had the appearance of fo many belts or zones. Serapio tells us that this and the botryoide cadmia were dug out of the mines; that is, that they were natural productions; but this is erroneous, and contrary to all the accounts of the antients.

TSHINKA, in the materia medica, a name by which fome authors have called the clove-tree, the tree which produces the fpice of that name. *Pifo*. Mant. A. p. 117.

TSIA, in botany, a name taken from the Japonefe, and ufed by fome authors for the tea tree.

TSIAM *Pangam*, in botany, a name ufed by fome authors for the tree whofe wood is the logwood ufed in dying and in medicine. Hort. Malab. vol. 6. p 3.

TSIANA *Cua*, in the materia medica, a name given by fome authors to the coftus root. Hort. Malab. vol 4. p. 15.

TSIN, in natural hiftory, the name given by the Chinefe to a ftone which they make great ufe of in their manufacture of porcelain ware. It is of a deep blue colour, much refembling Roman vitriol in appearance, and is found in lead mines, and fuppofed to contain fome particles of lead; its effects being the fame in the porcelain manufacture as thofe of cerufs or white lead; in making the other colours penetrate into the fubftance of the veffels. The deep violet colour that we fee fo beautiful on the China ware, is ufually made with this ftone. They find it about Canton and Peking; but the latter place affords the beft, and it fells at greatly the beft price.

The painters in enamel melt this ftone in their way, and ufe it very much; they form many beautiful works, by laying it upon filver; but it is apt to come off in time. When the *Tfin* is ufed in the porcelain manufacture, it is only ufed to the vafes that pafs a fecond baking, and are intended as the beft kinds.

The *Tfin* is prepared by only beating it to powder, not roafting it in the common way. They mix the powder with large quantities of water; and ftirring it together, they let it fubfide a little to feparate any earthy or extraneous matter that might be among it. They then let the powder fubfide. The water which is thrown away has no colour from this matter; and the powder itfelf is not of that fine blue it was in the lump, but of a pale afh-colour; but this recovers all its beauty when it is laid on the China, and baked. The fettlement taken from the water is dried and preferved in powder, and when it is to be ufed, they only mix it up with gum-water, or a folution of glue, and lay it on with a pencil. Obfervations fur les Coutumes del' Afie.

TSUBAKI, in botany, a name by which Kæmpfer calls the concellia. See the article CONCELLIA.

TUB (*Cycl*)—TUB-*Fifh*, in ichthyology, an Englifh name given to a fpecies of the *trigla*, commonly called the *flying fifh*, and by authors *hirundo*, *corvus*, and *milvus*.

It is diftinguifhed by Artedi from the other fifh of the fame genus, by the name of the *trigla* with a prickly head, and with three appendages on each fide to the pectoral fins. This is the only name to be judged fpecific for this fifh; for the others are fo vague in their fignification, that they have been applied by different authors to fifh of different fpecies, and even different genera, which had a power of fuftaining themfelves out of the water by means of their long pectoral fins. *Artedi*, Gen. Pifc. p. 74. See the articles HIRUNDO and TRIGLA.

TUBA, in natural hiftory, a name by which many old authors call the buccinum.

TUBBER, in mining, a name given in Cornwall to that mining inftrument, which is in other parts of England called a *beele*. It is an iron inftrument, pointed at each end, and having a hole in the middle for the handle. See the article DIGGING.

TUBBER-*Men*, are, in Cornwall, the people who work with this tool, and who are, from its other name of *beele*, called in other places *beel-men*. See the article BEELE.

TUBE *of a Flower*, among botanifts. See the article PETAL.

Glafs TUBES. See the article GLASS *Tubes*.

TUBEL, a word ufed by fome chemical writers to exprefs fcales of copper or brafs.

TUBEROUS, or TUBEROSE *Roots*, among botanifts, fuch as are large and flefhy, thicker than the ftalk of the plant, of an irregular figure, and wanting the characters of the bulbous. See the article ROOT.

TUBERA, *Truffles*, in botany, the name of a genus of plants, the characters of which are thefe; they are of a fungous flefhy ftructure, and are of a roundifh figure, growing fometimes fingle, fometimes many together, and always remaining under ground.

The fpecies of *Truffles* are only two. 1. The common *Truffle*; and 2. The tefticulated *Truffle*. *Tourn*. Inft. p. 565. See the article TRUFFLE.

TUBIPORA, in botany, the name given by Linnæus to the fea plants ufually called by authors *tubularia*. See the article TUBULARIA.

TUBOR *Terræ*, a name ufed by fome botanical authors for the cyclamen or fow-bread. *Ger*. Emac. Ind. 2.

TUBULARIA, in botany, the name of a genus of plants, the characters of which are thefe: That it grows under water, and is of the ftony hardnefs of coral, and compofed of a congeries of hollow pipes or tubes.

There is only one known fpecies of this, which is the purple *Tubularia*. *Tourn*. Inft. p. 575.

TUBULARIA *Foffilis*, in natural hiftory, the name of a fpecies of coral found very often foffile in Germany and Italy, and compofed of a great number of tubes, or longitudinal pipes, often refembling fo many worms ranged perpendicularly in the mafs. See Tab. of Foffils, Clafs 7.

They are ufually found either in maffes of a lax ftone, or in fingle tubules in thofe of the harder and firmer texture. In thefe two ftates this foffil makes two very different appearances; and, according to the different directions in the mafs, or the different views of them that the fections of it place them in, they make a number of very elegant figures. *Hill*'s Hift. of Foff. p. 641.

TUBULATED *Flower*, *Tubulatus Flofculus*, in botany, a term ufed by authors to exprefs thofe fmaller flowers, a great number of which go to compofe one large compound flower. Thefe are called tubulated in diftinction from another kind of them, which are, from their fhape, called ligulated The tubulated flofcules generally compofe the difk, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at the top, and is divided into five equal fegments, which ftand expanded, and in fome meafure bent backward. See Tab. 1. of Botany. Clafs 1.

TUBULUS (*Cycl*.)—TUBULI *Concamerati*, in natural hiftory, the name of a genus of the *Tubulus marinus*, diftinguifhed abundantly from all the others by its figure and inner ftructure.

They are long fhelly bodies, ufually either of a conic or cylindric form, or elfe refembling the dentales in fhape; and fometimes, but that very rarely, they have their fmaller end bent and twifted round. They are compofed within of a number of hollow compartments, each of which communicates with the next by means of a fiphunculus, which runs through the whole length in the manner of the thick nautilus, or the cornu ammonis. We know not thefe in their recent ftate at this time, but frequently meet with them foffile in the ftones brought from Sweden for pavements, and in fome others.

Some authors have called thefe by the name *alveoli*, confounding them with the conic body found in the belemnitæ. See ALVEOLUS. Others have called them *pyramidal entrochi*, others *obelifci marmorei alveolares*; and they are the bodies defcribed by Gefner and Aldrovand under the names of *lapides caudæ cancri* or *cancrites*. Some late authors have called them alfo *polythalamii*, and other *cone-ftones*. *Klein*. de Tubul. p. 7.

TUBULI *Foffiles*, in natural hiftory, the name given by authors to the cafes or *tubules* of fea-worms, found buried in the earth.

They are in their native ſtate of very various kinds, but by different accidents attending them in their accidental one, they are ſubject to a multitude of other appearances. They are found of very various ſizes, ſometimes compleat, and buried in the ſtrata of earth or ſtone; ſometimes they are more or leſs perfect, and are immerſed in maſſes of the *ludus helmontii* or *ſeptariæ*, and in this ſtate, they make one kind of *lapis ſyringoides*, or pipe-ſtone; but the moſt beautiful *ſyringoides*, or pipe-ſtones, are the parts of the bottoms of ſhips, or poſts fixed in the ſea, which have been pierced, in their original ſtate of wood, by theſe ſea worms, and afterwards, petrified with the caſes or *Tubuli* of the worms remaining in them; theſe are uſually of a pale yellow or whitiſh wax colour; and the body of the maſs of a browniſh or blackiſh hue, but retaining the ſtructure of the wood: of theſe, there are beautiful ſpecimens in great abundance on the ſhore of the iſland of Sheppy. We have the very ſame ſubſtances alſo buried in our clay-pits, about London and at Richmond; but in theſe the wood is highly ſaturated with the matter of the common vitriolic pyrites, and the pipes often filled with the ſame ſubſtance.

Thoſe *Tubuli* called *dentalia* and *entalia* are not leſs frequent, and are found of various ſizes; ſmall ſmooth ones are common in our clay-pits about London; and the larger ſtriated ones are not unfrequent in the hills of Yorkſhire; but they are much more plentiful in thoſe of France and Italy. *Hill's* Hiſt. of Foſſ. p. 648.

TUBULUS *Marinus*, or *Canalis*, in natural hiſtory, the name of a genus of univalve ſhell-fiſh; the characters of which are theſe: It is of an oblong figure, terminating in a point, and hollow within; ſo that it reſembles a tube or horn. Theſe are alſo called by the older writers *dentalia*, from their reſembling the tooth of a dog.

It has been a common error of authors to confound under the general name of *Tubulus marinus*, theſe ſhells, and thoſe very different ones of the *vermiculi marini*, which make a number of pipes or tubes joined together; theſe by their number and joinings, have induced a late French author to place them among the multivalve ſhells, while the *canales* are uſually ſingle and ſeparate, and can have no title to any claſs, but the tubular univalve one. Aldrovand obſerves, that the *Tubuli* called *dentalia*, and thoſe called *antalia*, differ only in ſize; and he thinks they have no title to the name *conchæ*, ſince they are neither of the nature of the common bivalve, nor univalve ſhells, ſuch as the patella and *auris marina*; but this is very idle, ſince by this rule the ſnails, and many other families, might be excluded as well as theſe. This author ſays, in another place, that the *antale* is formed of many circumvolutions; whence he ſeems to have taken in the *buccina* under this name; but later writers have more nicely diſtinguiſhed in theſe caſes. The ſea pencile is evidently of this genus, tho' extremely different from all the other ſpecies of it, in having its head pierced with a multitude of holes, in the manner of the head of a watering pot. Some authors, from the figure of the ſhell, call this *phallus marinus*, and the French call it *le priape*. *Aldrovand*, de Teſtac. l. 3. p. 382.

Of this general claſs of the *Tubuli* or *Canales*, there are four ſubordinate diſtinctions: 1. Some are ſtriated. 2. Some are ſtrait. 3. Some are bent like a horn: and, 4. Some are ſmall and even on the ſurface, and are bent a little into a figure approaching to that of a creſcent; theſe are now called by many *antalia*.

Of the ſtriated *Canalis*, we ſeem to have at preſent only one known ſpecies; tho' this varies ſo greatly in ſize and colour, that it might in its ſeveral ſtates be miſtaken by many for ſeveral ſpecies. There is alſo another very different form it aſſumes in our cabinets; this is owing to its being poliſhed, the ridges being by this manufacture taken off, and the ſhell made to appear extremely different.

Of the ſtrait kind we ſeem alſo to have only one ſpecies, tho' varied by accidents into ſeveral different appearances.

Of the crooked kinds we have. 1. The horn *Canalis*: this is a *Tubulus marinus* exactly of the ſhape of a horn moderately inflected. 2. The root-ſhaped *Canalis*. 3. The biſtort *dentalia*, or *Canalis*, of the figure of the biſtort-root. 4. The rape-*dentalia*, or *Canalis*, of the figure of the rape-root. 5. The *Canalis*, called vulgarly *dens-canis*, or the dog-tooth ſhell. 6. The *dens elephantis* or elephant's-tooth ſhell. 7. The whitiſh *Canalis*. And, 8. The greeniſh *Canalis*. To theſe is to be added, the *phallus* or *priape* of the French; called alſo by ſome of that nation the *arroſoir* or watering-pot; it is an oblong and ſtrait ſhell, with the head pierced full of ſmall holes like the head of a watering-pot.

Of the *Canalis* called by the French *antales*, we have only two ſpecies. 1. The white: And, 2. The yellowiſh *antalis*. Hiſt. Natur. Eclairc. P. 2. p. 245. See the articles PENICILLI *Marini*, DENTALIS, SOLEUS, BELEMNITES, and TUBULUS *concameratus*.

TUBULOSE-*Leaf*, among botaniſts. See the article LEAF.

TUCANA, in zoology, a name given by ſome to the toucan, a very remarkable American bird of the magpye-kind; but having a beak as long and thick as its whole body. *Ray's* Ornithol. p. 88. See the article TOUCAN.

TUCK *of a Ship*, the truſſing or gathering up the quarter under water; which if ſhe lie deep, makes her have a broad, or as they call it, fat quarter, and hinders her ſteering; by keeping the water from paſſing ſwiftly to her rudder; and if this truſſing lie too high above the water, ſhe will want bearing for her works behind, unleſs her quarter be very well laid out.

TUFECSI, a body of the Spahis, or horſe, in the ſervice of the Grand Seignior. *Pocock's* Egypt, p. 166.

TUFFO, in botany, a name given by the people of Guinea to a plant common in that country, and uſed in decoction to waſh ſore eyes with. It is of the ſun-flower kind, and is called by Petiver, *flos ſolis Guineenſis folio ſcabro flore minore*. It much reſembles ſome of the American ſun-flowers. Philoſ. Tranſ. N°. 232.

TUFTED *Duck*, in zoology, the Engliſh name for the *capo negro*, a ſpecies of duck with a blackiſh head, and a tuft of feathers hanging from it. See the article CAPO *Negro*.

TUGUS, in botany, the name of a ſweet aromatic plant, much eſteemed in the eaſtern parts of the world, and ſuppoſed by father Camelli, who very ſtrictly compared it with the accounts given by Dioſcorides and the antients of their amomum, to be that very plant. The cluſtered manner of growing of the fruit, together with its oblong ſhape, and the aromatic taſte of the ſeeds, ſeem greatly to countenance this opinion.

The *Tugus* is a plant of conſiderable height, growing up ſometimes to eight or nine cubits. Its leaves are of an oblong form, marked with large veins and ribs, covered with a ſoft hoary down underneath, and of a very agreeable aromatic ſmell. The flowers are red, and grow in cluſters, of a hand-breadth or more in length, in a kind of ear, ariſing either from the root, or from the main trunk of the plant. The fruit follows theſe flowers, and is no other than the inflated or enlarged cup of the flower, containing the ſeeds: this makes but a very thin and tender covering for them; and they, being delicious to the taſte, are much ſought after by birds, inſects, and field mice. One or other of theſe creatures uſually devours them before they become really ripe; and this makes the fruit ſcarce, even in the places where the plant grows, ſince very little of it can be collected.

Each fruit of the *Tugus* contains five or ſeven ſeeds; theſe are of an oblong figure, of a reddiſh colour, and of an agreeable aromatic taſte, but not too acrid.

The natives ſeem as fond of theſe, as the antients were of the amomum; and the young women ſtring them on threads, and wear them as bracelets; ſometimes they make the bracelets of the ſeeds alone; but more uſually they ſtring them alternately with pearls, and pieces of red coral: theſe bracelets they call *caropi*, as well as the fruit itſelf.

In ſome places, where the *Tugus* is ſcarce, they uſe the ſeeds of the abelmoſch, the cannacorus, or the ſago, inſtead of theſe of the *Tugus*; but the true are much more eſteemed. They are ſuppoſed, when worn by way of a necklace, to keep off the effects of a bad air, and to preſerve them from the bites of ſerpents or the centipes. If not a preſervative, they are however found, upon experience, to be a very good remedy in the laſt caſe, the common application for the bite of this animal being ſome of the ſeeds of the *Tugus* chewed in the mouth to a ſort of paſte.

The cluſter of fruit of the *Tugus*, or true amomum, when newly formed and unripe, ſomewhat reſembles the pſeudo-amomum of Garcias; but this likeneſs wears off as they ripen. Camelli, who hath given this excellent account of the *Tugus*, has added a figure of it in the Philoſophical Tranſactions, from which ſome at firſt ſight may object to the juſtice of his making it the ſame plant with the amomum; ſince Dioſcorides, and from him Pliny, affirm the leaves of the amomum plant to be like thoſe of the pomegranate; this no more agrees with his figure, than with his general deſcription of the common leaves of the *Tugus*, which are not at all like thoſe of that tree, but greatly larger and longer in their ſhape: but this is a difficulty eaſily cleared up, by obſerving that Dioſcorides, Pliny, and the reſt of the antients, when they deſcribe the amomum, never concern themſelves about the plant which produces that precious fruit, which probably they never ſaw; but all they mean by its leaves, are thoſe ſmall and ſhort leaves which they found adhering to the cluſter of the fruit, as brought over to them for ſale. Theſe are the leaves of the ear only, and theſe are not unlike thoſe of the pomegranate, on the plant while growing. Philoſ. Tranſ. N°. 248. p. 2.

TUI, in zoology, a name by which ſome call the *paroquette*. The word is originally Braſilian; and the names of ſeveral of the Braſilian ſpecies of this bird, deſcribed by Marggrave, have the word *Tui* as a part of them; as the *tuiete*, the *tuipara*, the *tuitirica*, and *tuiaputejuba*. See the article TUIETE, &c.

TUIAPUTEJUBA, in zoology, the name of a Braſilian ſpecies of paroquette, all over of a green colour, but in different ſhades, very deep on the wings, very pale and ſomewhat yellowiſh on the belly, and of a faint colour all over the reſt of the body. Its tail is very long; it is about the ſize of a ſwallow;

swallow; its eyes are large and black, and have a circle of yellowish green feathers round them, and over the beak, which is black and crooked; and on his head he has one spot of gold yellow feathers. *Marggrave*'s Hist. Brasil.

TUIETE, in zoology, the name of a Brasilian species of paroquette, of the size of a lark, and all over of a pale green colour, variegated with blue. The origin of its wings is blue, as are also all the ends of the wing-feathers, so that when the bird sits still, there is, as it were, a blue line seen running down each side; on its rump there is also a blue spot; its tail is but short; its beak small, crooked, and of a pale red; and its legs and feet grey. *Marggrave*'s Hist. Brasil.

TUITIRICA, in zoology, the name of a Brasilian paroquette, which is a little larger than the common kind; all over of a fine beautiful green, but deeper on the back and wings than elsewhere. Its beak is very hooked, and of a pale red; its eyes black; and its feet blue; its tail is but a little longer than the wings when closed. This is a species much esteemed in the Brasils, as it easily learns to talk, and becomes so tame, as to eat out of any one's mouth. *Marggrave*'s Hist. Brasil.

TULACUM, in natural history, a name given by the people of the East Indies to a species of yellow orpiment, of the coarser kind, variegated with red. They prepare this by several calcinations, and then give it internally in fevers, and many other disorders, esteeming it a sort of panacea. They say that gold may be extracted from it, which is not improbable; for it is well known, that some of the Roman emperors did actually procure gold from one of the other kinds of orpiment, which is now found at Gosselaer in Saxony.

TULIP, *Tulipa*, in botany, a large genus of plants, the characters of which are these: The flower is of the liliaceous kind, and is composed of six leaves, and somewhat of the form of a pitcher; the pistil occupies the center of the flower, and finally becomes an oblong fruit, divided into three cells, which contain flat seeds, arranged in a double order; the root is tunicated, and the fibres grow from its bottom.

The species of *Tulip*, enumerated by Mr. Tournefort, are these: 1. The yellow early-flowering *Tulip*. 2. The red early *Tulip*. 3. The purple early *Tulip*. 4. The amethystine early *Tulip*. 5. The early *Tulip*, with a dusky blackish purple flower. 6. The purple *Tulip*, with a pale cup. 7. The bright red *Tulip*, with a yellow cup. 8. The early white *Tulip*. 9. The early scarlet *Tulip*, with pale red edges, and red heart-fashioned spots at the bottoms of the leaves. 10. The early *Tulip*, with a crimson and red flower. 11. The variegated amethystine early *Tulip*. 12. The early *Tulip*, with a bright red flower, with white edges. 13. The early crimson *Tulip*, with white edges. 14. The variegated white and reddish early *Tulip*. 15. The early variegated red *Tulip*. 16. The variegated rose-coloured many-flowered early *Tulip*. 17. The early yellow variegated *Tulip*. 18. The early yellow *Tulip*, with red edges. 19. The early *Tulip*, of a blended red and yellow colour. 20. The beautiful scarlet *Tulip*, with yellow edges. 21. The broad-leaved yellow *Tulip*, with crimson edges. 22. The yellow *Tulip*, with edges striated with red, and a green bottom. 23. The yellow *Tulip*, with numerous small spots. 24. The yellow *Tulip* with gold-coloured spots. 25. The yellow *Tulip*, with rose-coloured edges. 26. The yellow *Tulip*, with red spots. 27. The yellow *Tulip*, with a red mark near the cup. 28. The yellow *Tulip*, with bright red spots. 29. The greenish yellow *Tulip*. 30. The pale lemon-coloured *Tulip*, with green streaks on the back. 31. The brimstone coloured *Tulip*, with deep red edges, and rose-coloured spots near the stamina. 32. The bright straw-coloured *Tulip*, with red edges. 33. The early purple variegated *Tulip*. 34. The rose-coloured *Tulip*, with yellow veins. 35. The bright red *Tulip*, with greenish streaks. 36. The *Tulip*, with reflex flowers of a bright red throughout within, and on the outside of a greenish colour, with a bright vermillion edge. 37. The early white *Tulip*. 38. The white *Tulip*, with green veins. 39. The white *Tulip*, with rose-coloured spots. 40. The white *Tulip*, with broad red spots. 41. The white *Tulip*, with red edges. 42. The silvery white *Tulip*. 43. The yellowish white early *Tulip*, with long red streaks. 44. The reddish white *Tulip*, with red edges. 45. The white wide-open *Tulip*, with red streaks. 46. The early narrow-leaved *Tulip*. 47. The early hyacinth-leaved *Tulip*. 48. The late flowering yellow *Tulip*. 49. The plain gold yellow *Tulip*. 50. The yellow *Tulip*, variegated with red and green. 51. The late-flowering scarlet velvety *Tulip*. 52. The late globose *Tulip*, spotted with gold colour. 53. The white *Tulip*, with a scarlet edge. 54. The white *Tulip*, variegated with a yellowish purple, and with yellow bottoms to the leaves. 55. The snow-white *Tulip*, with purplish-red edges. 56 The snow-white *Tulip*, with deeper purple edges. 57. The late-flowering stellate *Tulip*. 58. The changeable white-flowered *Tulip*, with red edges. 59. The scarlet *Tulip*, with white edges. 60. The late-flowering globose vermillion *Tulip*. 61. The late deep red *Tulip*. 62. The red changeable *Tulip*, with greenish spots in the middle of the petals. 63. The great branched late-flowering *Tulip*. 64. The smaller late-flowering branched *Tulip*. 65. The late green-flowered *Tulip*. 66. The late green *Tulip*, with double flowers. 67. The late flowering green *Tulip*, with white edges. 68. The late *Tulip*, with double red flowers. 69. The double late yellow *Tulip*. 70. The large dubious *Tulip*. 71. The largest dubious *Tulip*. 72. The middle-sized dubious *Tulip*, with sulphur-coloured flowers. 73. The yellow *Tulip*, with bright red spots. 74. The yellow *Tulip*, with red edges. 75. The large dubious *Tulip*, with orange-coloured flowers. 76. The middle-sized dubious *Tulip*, with variegated flowers. 77. The *Tulip* which bears bulbs in the alæ of the leaves. 78. The dwarf broad-leaved white *Tulip*. 79. The dwarf broad-leaved yellow *Tulip*. 80. The dwarf broad-leaved red *Tulip*. 81. The dwarf narrow-leaved *Tulip*. 82. The dwarf grassy-leaved *Tulip*. 83. The little yellow Italian *Tulip*. 84. The small broad-leaved *Tulip*. 85. The little red *Tulip*. 86. The cottony cretic *Tulip*. 87. The little French yellow *Tulip*. 88. The little yellow and purple *Tulip*. 89. The Persian variegated *Tulip*. 90. The Candey *Tulip*, with shining leaves. 91. The middle-sized changeable *Tulip*, with curled leaves adhering to the base of the flower. 92. The many-leaved yellow *Tulip*, called by some the monstrous double yellow *Tulip*. And 93. The great yellow *Tulip*, with jagged flowers, and spots of yellow and blood-red, in different parts of them. *Tourn.* Inst. p. 373. seq.

The characters of a good *Tulip* are these: 1. It must have a tall and strong stem. 2. The flower should consist of six leaves, three within, and three without; and the former should be larger than the latter. 3. The bottom of the flower should be proportioned to the top, and the ends of the leaves should be rounded, not pointed. 4. The leaves, when opened, should neither turn inward, nor bend outward, but stand erect; and the whole flower should be of a middling size, neither too large, nor too small. 5. The stripes must be small and regular, and should all arise from the bottom of the flower: The chives also should not be yellow, but of a brown colour.

Tulips are generally divided into three classes, according to their times of flowering; the early, the middling, and the late.

The early ones are not near so high as the late, but they are valued for their earliness, as they flower in February. The roots of these are to be planted in the beginning of September, under a warm pale or hedge. The proper soil for them is pasture-land with the turf rotted among it, and a mixture of one fourth part sand; this should be laid about ten inches deep, and should be renewed every year. If the weather is very severe when they first appear, they should be covered with mats; as also at nights, when they are in flower, if it be very frosty. When their flowering is over, and their leaves decay, the roots should be taken up and laid in a dry place, and afterwards cleaned and laid up in a safe place from vermin, till the September following.

The late blowers are propagated from what they call breeders, which are plain flowers, brought over principally from Flanders, which is the great mart for flower-roots; and these by culture, are changed into striped and variegated ones. They are also propagated by sowing the seeds; but this requires great care, as in the raising all the other fine flowers from seeds.

The seeds must be saved from the choicest flowers, and sowed in shallow pans or boxes of earth, in September. The spring following they appear like the leaves of grass, or young onions, and after standing two or three months these decay. The boxes are to be kept clear of weeds, and removed to different situations where they may enjoy the morning-sun, and be defended from sharp winds and frosts; at the Michaelmas of the following year they are to be removed out of the boxes into beds, where they should be planted two inches deep, and at two inches diameter from one another. In October, an inch depth of new earth should be sifted on them, and they are to remain two years in these beds; at the end of this time they will flower, and the best of them must be marked with sticks, that their roots may be distinguished when the leaves are decayed.

But there is no judgment to be passed either on *Tulips*, or any other flowers, on their first flowering; because the next year the good ones are often found to have degenerated, and the bad to have improved: After this, however, they may be concluded good or bad.

The breeders, as they are called, being thus raised, are to be shifted every year into fresh earth, and they will in time break out into very fine stripes. The earth they are planted in should be every year of a different kind, and the best general soil is made of a third part pasture-land with the grass rotted in it, a third part fine sea-sand, and a third part lime-rubbish; these should be mixed half a year before they are used, and often turned. The beds must be laid eighteen inches deep with this earth. This should be laid in first ten inches thick, and on this the roots should be placed in regular order, and at even distances; and then the other eight inches should be laid over these, the top of the bed being a little rounded to throw off the wet. Thus they are to remain till the buds appear, and then if the nights are very severe they are to be sheltered by covering them with mats. The flowers which break out into fine stripes here, should be separated after-

afterwards from the reft, and if they hold on their beauty to the laft, which the florifts call dying well, they will never return to plain flowers again; and the off-fets from the roots of thefe will always produce fuch flowers, and often more beautiful than thofe of the parent root.

When the *Tulips* have flowered, their heads fhould be broken off to prevent their feeding, which would make them flower much the worfe the next year. *Miller's* Gardener's Dict.

The Dutch have always been admirers of flowers, and before the prefent fafhion of cultivating the auriculas and carnations came up among them to the height it now is at, they took the fame care of *Tulips*. The prices they fold thefe at among one another, are amazing. Munting tells us, that in the years 1634, and the four or five following, they not only purchafed them at extravagant rates beyond credibility, but many of the burghers, fhopkeepers and tradefmen, quitted their fhops and trade, and addicted themfelves folely to the culture and cure of their *Tulips*. The fineft of them were then valued above gold or gems; and there is an account of one bargain for the purchace of that *Tulip* which they call the viceroy, preferv'd: The perfon who purchafed this, not having money, paid for it the following things; two lafts of wheat, four lafts of rye, four fat oxen, twelve fat fheep, eight fat hogs, two hogfheads of wine, four tons of beer, two ton weight of butter, a thoufand pound weight of cheefe, a bed, a fuit of cloaths, and a large filver beaker; the whole valued at two thoufand five hundred gilders. We have another account about the fame time, of twelve acres of good land offered for one *Tulip* root. And at a publick fale of a private perfon's collection there was made ninety thoufand gilders. This madnefs would have run yet higher among them, but the ftates at length took it into confideration, and finding it very detrimental to fubftantial and neceffary trade, put a ftop to it, and reduced the price. *Munting.* de Plant.

TULIP-*Tree*, a very beautiful American tree, which produces flowers fuppofed like thofe of the *Tulip*. Thefe trees ufed to be kept in tubs, and houfed in winter with great care; but fome of them having been planted out in the open air at Lord Peterborough's at Fulham, they throve much better than thofe which were fo carefully nurs'd up, and foon produced abundance of flowers.

The tree is commonly found wild in all the northern parts of America, where its timber is of very great ufe. The flowers are not in reality much like thofe of the *Tulip*, tho' vulgarly faid to be fo. The flowers are fucceeded by canes, which are often fent over from America; and the trees are frequently raifed with us, from the feeds contained in them. The feeds muft be taken out of the canes in fpring, and fown in pots of light earth, which muft be placed in a back bed, and covered with mats, and frequently refrefhed with a little water. When the young plants appear, they fhould be placed, during fummer, in a fhady fituation; and in winter they fhould be put into a frame, where they may have the benefit of the open air in mild weather, and be fheltered from feverity of frofts. In the fpring following, the plants fhould be tranfplanted into fmall pots, and taken the fame care of for four years, as while they were in the feed-pots; after this they will be ftrong enough to tranfplant finally into the places where they are to remain: it fhould be planted on a light loamy foil near other trees, but not over-fhaded by them. Some raife them from layers, but they are two or three years before they take good root, and then never make fuch ftrait and regular trees. *Miller's* Gardiner's Dict.

TULIPIFERA, a name given by Catefby, to the *liriodendron.* See the article LIRIODENDRON.

TULOS, a word ufed by fome medical writers to exprefs a callus.

TUMBABA, a word ufed by chemifts, to exprefs *fulphur vivum,* or crude fulphur.

TUMBALA, a word ufed by fome authors, to exprefs the *fquammæ* or fcales of any metal.

TUMBLER, (*Cycl.*) a name given to a particular fpecies of pigeon, called by Moore the *columba revolvens.*

It has its name from its peculiar property of *tumbling*, when it is in the air, which they are very fond of doing; and effect exactly in the fame manner as our pofture-mafters do it; by throwing themfelves over backward. It is a very fmall pigeon, and is always fhort bodied, full breafted, thin neck'd, narrow beak'd, and has a fmall fhort head; the iris of the eye in this fpecies, is ufually of a bright pearl-colour.

The Englifh *Tumbler* is ufually of one plain colour; black, blue, or white: the Dutch is much of the fame make, but has different colours, and is feathered on the legs fometimes; it has alfo a larger head, and thin fkin round the eye. Some of the fineft pigeons of this fort are bred from a mixture of the Dutch and Englifh kinds. Thefe pigeons are remarkable for the height they fly to; they never ramble far from home, but will rife almoft perpendicularly, till they appear no larger than a fparrow, or become quite out of fight; they will often keep at this height five or fix hours, and then come gradually down again: they never tumble when they are at any great height, but only as they afcend or come down again. There are particular times alfo, at which thefe birds will take much higher flights than at others; but they ought to be kept by themfelves, and practifed to it by the company of one of their own fpecies; for if they mix while young, with other pigeons, they will learn to fly as they do: a flight of a dozen of thefe birds fent out together, will keep fo clofe, as to be all in a compafs that might be covered with a handerchief; but they fhould never be turned out in foggy weather, or in high winds; in the firft cafe, they lofe fight of their home, and perhaps never find it again; and in the others, they are blown away; and if they return, it is not till another day; in the mean time lying out, they are in danger of cats, and other accidents.

Laftly, the hen fhould never be turned out with egg, for fhe is then fick, and not fit for flying; and befide often drops her egg, and the breed is loft by it. *Moore's* Columbarium, p. 39.

TUMEX, in the materia medica of the antients, a name given by authors to a fort of tutty, the fame with the *cadmia placitis* of Diofcorides and the Greeks. This was a worfe kind than the *botrytis*. The *botrytis* was formed on the roof of the furnace, and hung down thence in form of clufters of grapes; this was the pureft kind.

The *Tumex* or *cadmia placitis*, was a heavier and coarfer fort, which not being volatile enough to afcend to the top of the furnace, applied itfelf to the fides, and there formed a fort of coat or cruft, which was taken off at times, and referved for the more common ufes. This fort of cadmia, being formed by the fucceffive application of new coats of matter, at different times, was found to be of a cruftated texture, when broken tranfverfely, and refembled, in fome fort, the onyx, with its different zones or belts. It was therefore called by fome, *cadmia onychites*; and by Avifenna *mantheca*, which fignifies in the Arabian, *zonites*, or compofed of plates or zones.

TUMORS *of the Breafts*, *Mammarum* TUMORES. *Tumors* and inflammations of the breafts are a diforder that very frequently afflicts child-bearing women, and almoft conftantly happens, in fome degree, a few days after their delivery.

If the milk be impelled into the breafts too plentifully and forcibly, which frequently happens at that time, and the mother be at the fame time feized with a violent cold, or indeed be but affected by any violent paffions, the veffels become obftructed, and the breafts tumified, with great heat, rednefs, refiftance, and violent pain. The fame thing happens alfo very frequently to women who give fuck after their lying in, and often to fuch whofe milk is very fmall in quantity. Women at other times are alfo fubject to them, and even men have been known to have the fame diforder, from no other caufe than a great fright. One breaft of a man, opened on fuch an occafion, has afforded above two pounds of matter. This fort of abfcefs is ufually attended with a fever, thirft, head-ach, and difficult refpiraton, and is often preceded by fhiverings.

Tumors of this kind are generally prevented in thofe who do not intend to fuckle their children, by applying, foon after their delivery, plafters of fperma-ceti warm, all over the breafts, but perforated with a hole for the nipples. A moderately tight bandage ferves alfo as a help to keep away milk; and cooling plafters are of fervice to the fame purpofe, applied between the fhoulders. But if the lying-in woman intend to fuckle the child, there is no better way to prevent thefe *Tumors*, than very carefully to avoid colds, and violent paffions of the mind, and to let the child fuck very frequently, to prevent the milk from ftagnating. Plenty of fmall broth, and thin fluids, muft alfo be taken, which will prevent the milk, for the firft two or three weeks, from being too abundant, or from ftagnating in the breafts. But when the milk has once ftagnated, and a *Tumor* is begun, all endeavours are to be ufed to difcufs what has ftagnated in the fmall veffels, with all poffible expedition, both by internal and external remedies, in order to prevent the *Tumor* from running to a fuppuration, or into a fchirrus.

The beft external application, on thefe occafions, is the fperma-ceti plafter, covered with a warm bag, or cataplafm of falt and bran, or of chamomile, elder, and melilot flowers. The carminative feeds of fennel, annife, *&c.* are alfo very good external applications over a plafter, on thefe occafions. A calf's bladder, filled with a warm decoction of elder and chamomile flowers in milk, applied to the breaft, and renewed as often as neceffary, is alfo found of excellent fervice. Thefe not proving fufficient, recourfe muft be had to Venice treacle, rob of elder, litharge vinegar, cummin vinegar, and lime water, which muft be all applied hot to the breafts by means of linnen cloths dipped into them, and put to the breafts, as warm as can be conveniently borne.

If the breafts are very full of milk, part of it muft be difcharged by fucking, or by a glafs pipe; and this, with the other means, often repeated, till the pain and *Tumor* difappear.

If the *Tumor*, however, proves large, and will not be difperfed in four or five days by thefe methods, or when, as it very frequently happens, the furgeon is called in too late to put this method in practice, the beft method is to forward its maturation and fuppuration as quick as poffible, left it turn to

a

a schirrus or cancer by delay. The plaster of diachylon, with the gums, or some other such ripening plaster is to be applied forthwith; and with all convenient speed the proper cataplasms are to be used, to digest the matter; these are to be applied hot to the breasts, and very frequently renewed, keeping them on with large compresses and bolsters, the better to retain the heat. The *Tumor*, when the matter is ripe, will by this means either break of itself, or else it must be opened by the scalpel, the incision being always made in the lower part of the breast; and after the matter is all discharged, the wound is to be cleansed with the common digestives, incarned with the sarcotic, and healed with the balsam of Peru, or some other such vulnerary balsam. But where the suppuration has run very deep, the wound must be washed by means of a syringe, with vulnerary decoctions; and to prevent the opening from closing, before the bottom is healed, and filled up with new flesh, a sort of tent of scraped lint must be introduced, which may be shortened at every dressing, as the wound fills up, and at length wholly laid aside. *Heister's* Surgery, p. 187.

Encysted TUMORS, *Tumors* arising in different parts of the body, but contained in certain membranous coats: These are sometimes harder, sometimes softer, of a palish colour, and usually attended with little pain. These *Tumors* arise from obstructions either in the glands, or in the adipose membrane, more especially about the face and neck, where they occasion great deformity.

The membranous coat with which these *Tumors* are invested, is often of a considerable thickness, and is usually the coat of the disordered gland, or some of the adipose cells. At their beginning they are usually very small and moveable; but encreasing by slow degrees, they grow sometimes to an enormous bulk.

The consistence of some of these *Tumors* is soft and fluctuating, and of others more hard and firm. They are of all shapes and sizes, and some of them become hard as a callus, and unmoveable, while others are, for the generality, soft and moveable.

They are distinguished according to the consistence of their contents; some are called *atheromata*, from their contents resembling paste, others, which have them of the consistence of honey, are called *meliceres*; but if they are of a fatty substance, like suet or lard, they are called *steatomata*. If they happen in a gland which becomes indurated, they are called *schirrous*; and lastly, when they are of a fleshy consistence, they are called *sarcomata*. Some of these *Tumors* have been found also full of hair.

They are distinguished by others according to the places where they are situated. Those seated under the scalp are called *talpa*, *testudo*, or *lupia*. Those in the neck, *strumæ* or *scrophulæ*; and those in the hands and feet, especially if among the tendons, are called *ganglions*.

There is no general method for the cure of them; but the surgeon, according to their different circumstances, attempts this by discussion, suppuration, or extirpation. *Heister's* Surgery, p. 323.

Fungous TUMOURS, in surgery, are a sort of swellings much approaching to the nature of the œdema, and are often disorders of very bad consequence.

These are *Tumors* of a limb, taking their rise at the joint; they look pale, are void of heat and pain, easily yield to the pressure of the fingers, but rise again instantly on removing the finger, leaving no pit or impression behind; tho' no joint of the upper or lower limbs can be said to be secure from this disorder, yet the knees are ever most subject to it, and that because they abound in fat and glandular bodies, which are concealed among the ligaments and tendons. It is what we commonly know by the name of white swellings or scrophulous *Tumors* in the joints, and is of several species; for some *Tumors* of this kind are larger, some smaller, some softer, some harder; and with regard to the state of the inspissated fluid, some are more, some less glutinous. The noxious humours are usually situated without the joint, and are, in that case, properly what we are here treating of. But in some they are collected and retained in the joint itself, as the serum is contained in the testicle in an hydrocele. This last disorder is not improperly to be called a dropsy of the joint; and this may be commonly distinguished from the external fungous *Tumors* of the joints, by the inlargement which appears all round the joint; whereas the fungous *Tumor* is usually situated more on one or the other side of it.

The proximate cause of these *Tumors* is, doubtless, the viscidity of the serum about the ligaments of the joints, which is apt to stagnate after the ligaments have received any considerable violence from a fall or a blow. The *Tumor* sometimes rises in the external parts, sometimes in the articulation itself, by which the ligaments being weakened, the part loses its natural motion; and when the nerves or blood-vessels are greatly pressed upon by the *Tumor*, the parts below are usually deprived of nourishment; and while the joint, by degrees, becomes greatly enlarged, the parts below it diminish and waste.

In order to render the cure of recent and milder *Tumors*, of this kind, the more easy, by dispersing remedies, it will be proper to rub the disordered part with warm cloths every day, fomenting it afterwards with tartarized spirit of wine; and this method is to be carefully pursued, till the natural strength and form of the limb are restored. Purmannus's fomentation is excellent for this purpose. It is made of six ounces of roch-alum, an ounce and half of Roman vitriol, and two handfuls of sage leaves, boiled in a quart of herring-pickle, mixed with a pint of the sharpest vinegar; it is to boil together for about half an hour, and then to be used as the before-mentioned.

When the tumours begin to disperse, and the parts to recover their strength, it will be a great forwarding of the cure, to foment the limb well several times every day with tartarized spirit of wine, or with the fœtid oil of tartar, laying the bandages carefully on every time afterwards, to defend it from the injuries of the external air, of which it is very susceptible: And lastly, the following is an application by which many of these *Tumors* have been perfectly and happily cured. Take litharge half a pound, bole armenic an ounce, mastic and myrrh of each half an ounce, white wine vinegar a pint; mix these together, and let them boil for a quarter of an hour, and let coarse linnen rags be dipped in this liquor, or fine ones often doubled, and applied morning and night in bed to the part; and at the same time the patient is not to omit the proper internal remedies, which are the attenuants and sudorifics.

But if the *Tumor* be of long standing, and will not give way to any of these remedies, all the hope left is to make an incision into the dependant part of it, taking great care to avoid wounding the ligaments or tendons of the joint; and by this means the stagnating serum, if contained in one cavity, is instantly evacuated, and if it be lodged in several different cells, it will yet make its escape through the same orifice in the space of a few days. Before the incision is made, in this case, the *Tumor* should be pulled down as low as may be with the fingers, and a tight bandage made above to retain it in that situation; by this means the most convenient part for the incision to be made in will lie fair, and when the opening is made, the serum will readily burst forth like blood on the opening a vein, or lymph in the tapping for the hydrocele or ascites. When this is done, if any *Tumor* still remains, the part is to be dressed with diachylon or oxycroceum plasters, and washed with lime-water or spirit of wine. By continuing the applications, what remains inspissated in the *Tumor* will entirely disperse. When the limb is restored to its natural shape, the wound is to be healed with vulnerary balsams, diligently avoiding the use of fatty or oily medicines, as they are hurtful to the tendons and ligaments, with which those parts abound. If the serum, contained in the *Tumor*, is so glutinous that it cannot discharge itself for want of fluidity, throw up attenuating injections at every dressing. The best for this purpose are those prepared from a decoction of agrimony, birthwort, or ladies mantle, mixed with honey, in which rosemary or celandine have been infused. Notwithstanding that such of these *Tumors* as are opened by the knife are soonest discharged and healed, yet some surgeons prefer the application of caustic medicines to the knife, discharging the serum upon the falling off of the eschar. In either case it would be proper to warm and invigorate the ligaments and tendons, especially when the disorder falls upon the knee, by the use of some nervous ointment, or aromatic spirit.

It too frequently happens, however, that after the wound has been cauterized, the inspissated serum having been first ever so carefully evacuated, that there will be a fresh collection of a vitiated fluid in the part. In order to prevent therefore an accident of this kind, let the patient be kept in a strict course of purging, sudorific and attenuating medicines, and the wound be kept open with tents, cleansing it thoroughly every day, by throwing up an injection, such as has been before directed. It may be proper also sometimes to inject lime-water, and afterwards to cover up the part with a warm plaster, or foment it with some liquor of the same intention. It is, however, finally to be observed, that it is not every fungous *Tumor* of the joints that can be opened with safety; for if the *Tumor* is of a very long standing, hard, or of a very large size, or the patient is of an infirm weakly habit of body, the knife must not be thought of, as it would occasion disorders worse than the first; to wit, caries, fistulas, and gangrene. *Heister's* Surgery, p. 285.

We have an account of a very extraordinary *Tumor* in the knee of a person, whose leg was taken off by Mr. Peirce at Bath. The leg and foot weighed sixty-nine pounds. See Phil. Trans. N°. 452. Sect. 4.

Windy TUMORS. These *Tumors* are formed by the air inclosed under some membrane, which is dilated more or less by that air, according to its quantity, and from within which it cannot escape, at least not of a certain time.

These *Tumors* are usually round, circumscribed, or determinate, and if they are struck with a finger, they give a sound like that of a blown bladder. They have no particular seat in any part of the body, but almost every part is more or less liable to them.

The great difficulty in accounting for these *Tumors*, is to say how the air comes to be collected there; but the most probable cause seems to be the collecting together of a quantity of a fluid

fluid in some adjoining part where there is some obstruction. The air, which is naturally mixed with all the fluids in the human body, always remains in them while they continue in their fluidity, and in their natural motions; but when they are amassed together in any particular part, and their fluidity and motion become impaired, the air that was in them becomes immediately in a state of disengaging itself from them; and it usually does so disengage itself. The membranes of the part where this collection of the fluids is made, are relaxed by it, and their pores consequently enlarged, and the air which has disengaged itself, escapes easily by these pores, while the fluids are much too thick to be able to follow it, so that it escapes alone.

The air, thus separated, runs under some other adjoining membrane, which it immediately elevates and distends. As the liquors amassed in the other place are not yet so far altered, but that part of them are continually received again into the road of circulation, and consequently more fresh fluids left in their place: these fresh fluids contain more air, which is, by degrees, separated from them, as from the others, and finds its way, in the same manner, to the place where the rest of the air is; and hence is the continual increase of the *Tumors*; and it is very evident, that when a *Tumor* is once formed in this manner, it cannot go down, even though the first extravasation, which occasioned it, should wholly disappear, and all the fluids be again received into their vessels again; but, in fine, the air included in the *Tumor* may dilate the membrane, which encloses it, so far, that its pores may be sufficiently opened to let it escape; this, however, wholly depends on its quantity, and on the closer or laxer texture of the membrane.

Those acute pains which we call stitches in the side, and which are principally felt on the sides, and about the region of the breast, may possibly be sometimes occasioned by acrid humours, which prick the nervous fibres; and the pain, in this case, is sometimes very acute, and even attended with a sharp fever; but very often this pain is occasioned only by air included between the fibres, where it occasions a violent tension and pain; but often the relief from this is sudden, the natural elasticity of the parts restoring all to their pristine state, and the air being condensed again almost as soon as dilated. Very often the natural spring of the parts either entirely sends off the air, or else drives it to another place; and this is the reason why pains of this kind are often found to shift about and change place so suddenly.

But of all the effects of air in the body, none is so great as that found in the bodies of those who have died by loss of blood, whether that has been occasioned by wounds or natural hæmorrhages. There may, in this case, often be perceived, through the coats of some of the veins, little bubbles of air floating on the surface of the blood contained in them; and this is no way to be wondered at, since as a great part of the blood has been lost out of the body by the hæmorrhage, the remainder has been by this much injured in its power of motion, as well by loss of quantity to impel it, as of animal spirits to enliven it; and by the want of strength in the arteries to perform their pulsations, in order to the keeping it in motion; the consequences of these joint causes, according to the principles before laid down, must be, that the air must escape out of the blood, and appear freed as we see it.

If we perceive this only in the veins, the reason is plain, since there is no blood any where but in the veins of persons who have died in this manner, the arteries having been already drained; whereas, in other bodies there always remains some blood, though but little, in the arteries. Another consequence of dying by an hæmorrhage is, that the ventricles of the heart are always found empty of blood; which is not the case in those who have died by other means. The cause of this is, that the force with which the veins drive up the blood from their extremities toward their larger trunks, and thence to the heart, is much weaker than that by which the arteries throw the blood they contain toward the extremities. This being allowed, a great loss of blood cannot but diminish the force of the arteries and veins both; but its effect will certainly be greater on the veins; so that they may wholly lose their force before the arteries have lost theirs; and these last making at length one general contraction, may throw off all their contents into the veins, while they, having already lost all their power, can no longer move it forwards; so that, in this case, it all remains there, and consequently what blood remains in the body, must, on opening it, be found lodged in the veins.

It is sometimes observed in bodies which have died of hæmorrhages, that the smaller vessels, at considerable distances from the heart, have been all full and distended with wind; in this state it is not impossible that they may have been sometimes mistaken for lymphatic vessels; but in tracing them up to their trunks, they soon discover what they really are. After a large quantity of blood has been lost, it is plain that there can be but little in the lungs, while the quantity of air is always equal there; and as the air always easily disengages itself from the blood, when it is less fluid, and in smaller quantity than before, the air may, in this case, pass from the lungs to the heart with the blood, without being so intimately mixed with it as at other times; when the arteries have, after this, not power enough to impel the blood into the veins, their power may yet be sufficient to drive this wind into them, it being much lighter, and more susceptible of motion; and this alone seems a very natural and easy solution of this phænomenon. This supposes, indeed, that the motion of the blood being stopped, death comes on, as well by this means, as by the stoppage of respiration. Mem. Acad. Par. 1714.

TUMORS *of the Testicles*. See the article TESTICLES.

TUNA, in botany, the name by which some authors have called the *opuntia*, the Indian fig, or *ficus Indica*, as it is usually called. *Jonſ.* Dendr. p. 57.

TUNALLUS, in ichthyology, a name given by Albertus, and some others, to that species of the coregoni called by the generality of authors the *thymallus*, by us the *grayling*, or *umber*. Artedi distinguishes it by the name of the *coregonus*, with the upper jaw longest, and with twenty-three rays in the back fin. See the article COREGONUS.

TUNG, in natural history, the name given by the Indians to a little insect, called by the Spaniards *Piqué*, which is very common, and very troublesome in some parts of the East and West Indies.

It is of the size of a small flea; its place of laying its eggs is within the skin of the human body, and it diligently searches opportunities of doing this, and often succeeds in the attempt, to the great pain and trouble of the person who suffers it. The creature, knowing that it shall be soon crushed to death under the skin, generally makes its way either under the nails, or where there is some callus on the surface; there it eats its way along, and, in fine, lays its eggs, which hatch into so many young ones, and spread themselves between the flesh and skin all over the finger and hand, if not prevented by taking out the old one in time.

The person often does not perceive the creature's getting in, it enters so gradually and easily; but he is soon advertised of the place where it is by a violent gnawing pain, the creature really eating its way as it goes along. The only remedy in this case is, to enlarge the orifice at which it entered, and take it out whole; the wound soon heals up, and there is an end of the matter. This may often be done with the point of a needle; but if not, it is much better to submit to the opening it with a lancet, than to the ill consequences which otherwise will attend it. Observ. sur les Coutumes de l'Asie. p. 184.

TUNICA (*Cycl.*) TUNICA *Albuginea*, the name of the membrane that covers the body of the testicles. It is of the same substance with others of the thicker membranes of the body, and is supplied with proper vessels for its nourishment; but under this the body of the testicle is, on a strict examination, found to be only a congeries of vessels rolled up in regular and even folds, without any intermediate substance of whatever kind. It is necessary to have recourse to the use of glasses to see this structure; and there is one caution necessary to the persons who would make the experiment, which is, that as these vessels all contain a liquor, which being somewhat thick and whitish, soon dries when exposed to the air, and, in drying, acquires somewhat of the appearance of flesh, it is very apt to deceive the inspector into an opinion, that there is really a fleshy matter in the substance of the testicle, distinct from the vessels: What will set this right, will be the observing, that the object, when newly cut, and immediately viewed, has none of this flesh-like matter about it; but only a mucous humour may be seen ouzing from the mouths of the rolls or folds of the vessels where cut; and that afterwards, when the flesh-like matter becomes visible, it is only seen about the ends and edges of the piece of the testicle that is examined, and only in those places where it was before seen ouzing out in form of a fluid from the apertures of the vessels.

These vessels, of which the substances of the testes are composed, are extremely tender and fine; yet, while the subject is fresh, they may, by a delicate hand, be drawn out, and will sometimes be extended to half a yard long without breaking. The single vessel, when thus extended, has much the appearance of the external coat of the epididymis, and its corrugations. These tubes receive their contents in some sort from the arteries, and have a communication with them, insomuch that on injecting a coloured matter into the *arteria preparans*, and afterwards opening the testicle, this matter will be found to have made its way into several of the tubes composing the rolls or folds of the substance of the testicle.

It might be supposed, that this colouring of the tubes was only external, and that the matter of the injection had only spread itself on their surface, or penetrated into the plexus of vessels that cover them; but, on trying to wash off the colour with spirit of wine, it proves so permanent as not to give way to that; and, on curiously examining a part of a single tube pricked with a fine needle, the coloured matter of the injection may be distinctly seen ouzing out of the puncture. The glands in general are no other than the testes; and the pancreas, and many other parts of the body, have no parenchyma or intermediate fleshy substance between the vessels, but are made up of vessels or tubes filled with peculiar liquors, and generally owe their colour to that of the liquor they contain. No reputed gland is any other thing than a mere congeries of vessels, through which peculiar juices come and go; and the very coats

coats of the larger veffels fo much approach to this ftructure, that, though not wholly compofed of other veffels, they have fo many in them, that the far greater part of their fubftance is made up of thofe veffels, and of the fluids which are continually paffing through them, and which keep open their paffages.

Thefe liquors being deftined for the fupport of the coat of the veffel, are in general the fame with that which flows within it.

As to the tefticles being wholly compofed of thefe veffels or tubes, without any other fubftance, it is, perhaps, carrying the matter too far, to affert it in fuch abfolute terms. That there are certain membranes, connecting feveral of the veffels into, as it were, one roll or tube, appears in the nice examination of the tefticles of the rabbit, and fome other animals; and though there be no parenchyma, or flefhy fubftance, yet it is very probable, by the lubricous appearance of thefe veffels on the outfide, that there is originally among and between them a mucous or flimy matter, which may ferve in the place of a parenchyma. Philof. Tranf. N°. 53.

TUNICATED *Roots*, among botanifts, fuch as are formed of a multitude of coats furrounding one another. See the article Root.

TUNNEL-*Net* (*Cycl.*)—This net muft be made of three-twifted thread, and muft not be too thick: It fhould be dyed green, that the colour may give no fufpicion to the birds, and the mefhes fhould be about two inches and a half broad.

Into the hind mefhes, at the larger end, there muft be put a fmooth wooden rod, about the bignefs of a gun-rammmer; of this muft be made a fort of hoop, both ends being tyed together, and at different diftances from one another, there muft be placed many more fuch, which are to be rounded in the fame manner, and are to fupport the net its whole length in the tunnel form. Two ftakes, or ftrong pegs, muft be faftened at the fides of the entrances into the net, and one at the farther end, or narrower part; the two firft are to keep the mouth of the net fufficiently extended, and the laft is to keep it pulled out lengthwife to its full dimenfions, the hoop preventing its falling in.

There muft be ufed with this net two others of that kind, which they call *halliers*. Thefe are long and ftrait nets, and are to be faftened down to the mouth of the *Tunnel-net* on each fide, extending feven or eight fathoms on each fide from it, fo as to take in fourteen or fixteen fathoms in front, befide the breadth of the mouth of the *Tunnel-net*, and to direct all that fhall move forward within that compafs into the net.

In order to ufe this net, a covey of partridges is to be found, and then the net is to be placed at a confiderable diftance behind them: When this is fixed, the fportfman is to take a compafs, and get before the birds with a ftalking horfe or ftalking ox, and then to move forward, driving them towards the net. This is to be done gently, and carefully, they are not to be driven at once ftrait forwards; but the fportfman is to wind and turn about, and, at times to ftand ftill, as if the horfe was grazing. If the partridges, in the time of driving, make a ftand, and look at the machine, it is a fign they fufpect it, and are ready to take wing: In this cafe the fportfman muft ftand ftill, or even go back a little; and when they are become compofed again, he is again to advance upon them. If any fingle bird lies remote from the reft, the fportfman muft take a compafs round him, and fetch him in; for if he takes wing the reft will all follow; in this manner, with patience and caution, the whole covey may be driven like a flock of fheep up to the nets. A real horfe, trained to the purpofe, is, however, much better than a ftalking machine.

The halliers, or wings of the *Tunnel* muft not be pitched ftrait, but in a fort of femicircle; and the birds, when they ftop their march, will run along them to the middle, where the mouth of the *Tunnel* is open.

When they come to the mouth of the *Tunnel*, the old ones will make a ftand, as if to confider what was before them; but on preffing gently on them with the horfe, the young ones will run in, and then all the reft will follow.

The fportfman muft then make all the hafte he can to the mouth of the net, to fecure them from coming back again. The ftalking-horfe is to be made of canvas or linnen, painted in the figure of a horfe, and fupported by two crofs fticks, by which the fportfman carries it before him, fo that his own body is compleatly hid by it. There are to be holes made through it, by which the fportfman fees his game; and the tail is to be made of hair, and to hang loofe from the body, that it may play in the wind in moving.

TUNNY, a name given by us to the Spanifh mackrel, a larger fifh of the fcomber kind, called by authors *thynnus* and *arcynus*, by Salvian *limofa*, and *pelamys* by Ariftotle, Ælian, and the other old writers. See Tab. of Fifhes, N°. 29.

It is properly a fpecies of the fcomber, and is expreffively named by Artedi, the fcomber with eight or nine fins in the hinder part of the back, rifing out of a furrow; and a furrow at the place of the belly-fins. See the articles Thynnus and Scomber.

TUNUPOLON, in zoology, the name of an Eaft Indian fpecies of viper, found principally in the ifland of Ceylon. It is of a fmall fize, and of a fine fattin-like glofs, beatifully variegated with different fhades of brown. *Ray*'s Syn. An. p. 332.

TUPUTA, in zoology, a name under which Nieremberg has defcribed an American bird, which, he fays, is like a pheafant in fhape, and loves low bufhes and fedgy places, never flying into high trees, and which has no flefh, but merely a vaft affemblage of living worms between the fkin and the bones. Mr. Ray has fufficiently laughed at the abfurdity of this account; which probably had its origin from the diftempered ftate of one bird of fome well known fpecies; though Nieremberg thinking the worms a fufficient character, has given no farther account of it. *Ray*'s Ornithol. p. 298.

TURBAN-*Shell*, *Cidaris*, in natural hiftory, the name of a genus of the echinodermata, which are of a hemifpheric or fpheroidal figure, and have their name from the Latin *Cidaris*, a *Perfian Turban*, as in fome degree refembling that headdrefs. See Tab. of Teftaceous and Cruftaceous Animals, N°. 1, 2, 3, 4.

Of this there are feveral kinds: 1. The *Cidaris miliaris*, fo called from its eminences or tubercles, being as fmall as the grains of millet. Of this there are three known fpecies; one with a high top, a fecond with a flatter and more of a hemifpheric figure, and a third which is fomewhat angular.

The fecond kind is the *Cidaris variolata*. The eminences of this are of a middle fize, between thofe of the miliary and mammiliary kinds, and fomewhat refemble the puftules of the fmall-pox when ripe, whence they have their name. Of this kind there are three known fpecies: 1. The brifly echinus of Rumphius. 2. The fmall ovarius of Langius. And 3. The Turk's *Turban* of moft authors. And to thefe may be added a fourth, a very remarkable one of an elliptic form, with very few tubercles, and a large mouth. *Klein*'s Echinod. p. 17.

The third kind is the *Cidaris mammillata*, or the mammillary echini. The tubercles of thefe are very large, and imitate the appearance of breafts, with nipples to them. Of thefe alfo there are two known fpecies. 1. The fingered echinometra of Rumphius. 2. The fpecies called the *moor's Turban*.

The fourth kind is the *Cidaris coronalis*; the tubercles of which are fo difpofed as to make it reprefent the diadem of antient kings. Of this there is only one known fpecies, and that extremely rare.

The fifth kind is the *Cidaris corollaris*; the tubercles of which are fo difpofed, as to imitate the garlands made of flowers. Of this there are two known fpecies, the one thicker, and the other thinner.

The fixth kind is the *Cidaris afterifans*. Of this there is only one known fpecies, the tubercles of which are difpofed in form of a radiating ftar.

The feventh is the *Cidaris affulata*, or tiled *Cidaris*. This is fo called, becaufe the feveral parts of the fhell are joined tranfverfely to one another. Of thefe there are eight known fpecies. 1. Olearius's fpecies, compofed of twenty orders of affulæ. 2. Aldrovandus's *echinometra maxima pelagica Sardica*. 3. The flammated kind, the vertex of which has ten rays, like fo many flames. 4. The variegated kind, whofe tubercles are variegated with white, and a fine rofe colour. 5. The puftulofe kind, which is thick befet with tubercles, refembling ripe puftules. 6. The granulated kind; the tubercles of which are very fmall. 7. The fmooth kind, with a flat crown. 8. That fpecies called by Mercatus *anachytis*, which has a very gibbofe back.

The eighth kind is the *botryoide Cidaris*. Of this there is only one known fpecies, which bears a very great refemblance to the central part of the fea ftar-fifh, with contracted fragments of the rays.

The ninth kind is the *Cidaris toreumatica*. This has its name from the Latin *toreuma*, fignifying a chafed or wrought plate, the fuperficies of this being as if chafed and engraved into figures. There is only one known fpecies of this genus.

This clafs of the echinodermata is made out by the affiftance of the foffile, as well as the recent animals; many of the kinds being now unknown on any fhores. Id. Ibid.

TURBINATA *Offa*, the name of the turbinated bones of the nofe. See the article Nose, *Cycl.*

TURBINATUM, a name given by fome to the glandula pinealis.

TURBINES, in natural hiftory. See the article Turbo.

TURBINITÆ, foffile fhells of the turbo kind, or ftones found in thofe fhells. Among the people who have objected to the fhells found buried in the earth being the remains of real animals, it has been alledged by fome, that thefe in particular are always of a blackifh or afh-colour, when found in chalk or clay, and white from the rocks, or when they have been bedded in ftone.

To this Auguftino Scilla has very judicioufly anfwered, that the *Turbinitæ* found in chalk and clay, are not the real fhells, but are ftones which have been formed in thofe fhells, the fhells themfelves, which gave fhape to them, being decayed and gone; whereas thofe found bedded in ftone, are, at this time, the fhells themfelves, preferved in their natural beauty by the hardnefs of the bed they lie in; or, if not real fhells, that the only ftone which can form itfelf there being fpar, that is white, and the fhells giving origin to fuch a ftone will

appear as white in its fubftance, or more fo, than they would in their own. *Auguftino Scilla*, de Petrifac.

TURBAT, in ichthyology, the fame with *Turbut*. See the article TURBUT.

TURBIT *Pigeon*, a particular fpecies of pigeon, remarkable for its fhort bill, and called by the Dutch *cort bek*, that is, fhort-beak. Moore calls it in Latin, *columba fimbricata*: And its Englifh name feems no other than a bad pronunciation of its Dutch one. It is a fmall and fhort-bodied pigeon, and has a beak no longer than that of a partridge; the fhorter this is, the more the pigeon is efteemed: It has a fhort round head, and the feathers upon the breaft open, and reflect both ways, ftanding out like the frill of the bofom of a fhirt. This is called by many, the *purle*, and the more the bird has of it, the more it is efteemed. The tail and back are generally of one colour, as blue, black, red, yellow or dun, and fometimes chequered. The flight feathers, and thofe of all the reft of the body, are white. They are a light nimble pigeon, and, if trained to it, will take very high flights, in the manner of the tumblers. *Moore*'s Columbarium, p. 53.

TURBITH (*Cycl.*)—There is great uncertainty and confufion among the old writers, in regard to the drug called by this name. Avifenna, and the reft of the Arabian phyficians, all prefcribe *Turbith*; and we are apt to believe, that they mean our *Turbith*-root; but it does not appear fo either from the form or virtues of that medicine.

All the writers of later ages have placed the *Turbith*-root among the things of value and ufe, brought as merchandize from the Eaft Indies; and Garcias juftly defcribes the plant: But his defcription plainly proves, that it cannot be the *Turbith* of the Arabians; for all that they have faid about the *Turbith* is tranflated from Diofcorides, and he has faid it of the tripolium.

The tripolium of the Greeks is therefore the *Turbith* of the Arabians, and this is a very different thing from the *Turbith* of our times. Mefue indeed feems to make the *Turbith* a different thing from what all the others have made it; he fays, that it is the root of a plant of the lactefcent kind, which had leaves like the ferula or fennel giant. This is a defcription that can by no means agree either with the tripolium of the Greeks, or the *Turbith* of Garcias; and proves, that if Mefue was right in faying it belonged to the plant, of which what he calls *Turbith* was the root, then his *Turbith* is different from both the one and the other of thefe. Some other of the writers on thefe fubjects have alfo called two roots, different from all thefe, by the names of white and black *Turbith*. The black *Turbith* is the pityufa-root, a kind of fpurge; and the white *Turbith* the root of the alypum.

Avifenna calls the *Turbith*, *terbadh*. Some have fuppofed this word expreffed a thing different from all the others; but this is by no means the cafe, for the *Turbith*, or *turbadh* of Avifenna is the fame with the *Turbith* of Serapion, that is, with the tripolium of Diofcorides.

From this *turbadh* of the Arabians, the later Greek writers have formed the word τυρβιθ; but they have applied it, in a very loofe and vague manner, to feveral very different things. Neophytus makes the *Turbeth* a fpecies of myrobalan; but in this he errs, no other author having ever underftood the word in that fenfe. Upon the whole, it appears, however, that there are three different plants, called *Turbith* by authors, the tripolium, the pityufa, and the alypum; but all thefe are different from the Indian *Turbith*, which is the *Turbith* of Garcias, and the *Turbith* of our fhops. There is alfo in one part of Avifenna an account of *Turbith* different from all thefe, and making it a kind of wood.

TURBITH-*Mineral* has been ufed as a fternutatory, and is faid to have made wonderful cures in diftempers of the eyes. Mr. Boyle relates a cure of this fort, performed by the famous empiric Adrian Glafs-maker on Mr. Vatteville, a Swifs officer of diftinction in the French fervice, and totally blind. This gentleman was ordered to fnuff about a grain of *Turbith* up each noftril, which immediately operated in a violent manner by vomit, ftool, fweat, falivation, and the lacrymal glands, for twelve hours together; and alfo caufed his head to fwell greatly; but within three or four days after this fingle dofe had done working, he recovered his fight. *Boyle*'s Works abr. vol. I. p. 103.

TURBO, the *Screw-Shell*, in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe: They are univalve fhells, with a long, wide, and depreffed mouth, in fome fpecies approaching to a round fhape, and in fome having teeth, in others not. They all grow narrow toward the bafe, and are auriculated, and terminate in a very long and fharp point. See Tab. of Shells, N°. II.

Aldrovand, and many others of the old authors, make no difference between the *Turbines* and fcrew-fhells, though the diftinction of the genera is very obvious; the fcrew-fhells having a long, large, and dentated mouth, which terminates toward the bafe in a narrower aperture than elfewhere: And the fhell itfelf always runs to a very fharp point at the end; whereas the *Turbines* terminate in a lefs fharp point, and have thicker bodies, and always much wider mouths. The fcrew-fhells are indeed very eafily confounded with the buccina; and it requires more accuracy to diftinguifh them, than has fallen to the fhare of the generality of writers on thefe fubjects an age or two ago. Aldrovand and Rondeletius have confounded thefe genera, and have brought in a third among them, by the epithet *muricatum*, which, when applied to the buccinum, is generally obferved to bring into that family a fhell of the murex clafs, and which might have been very properly called by that fhorter name.

That thefe may be, however, more juftly diftinguifhed for the future, it may be proper to add the genuine character of the *fcrew-fhell*; which is, that it is of a very long and flender fhape, and ends in a very fharp point. Its fpires run on imperceptibly, without any great cavity, and the bafe is fmall and flat, as is alfo the mouth. Lifter, who was for making all the long fhells buccinums, calls the fcrew-fhell, the intervals of the fpires of which are deep, a long twifted buccinum, with a flat mouth. Fabius Columna has confounded yet more the genera of fhells together; he brings in the trochus into the family of the buccina; and tells us, that the words *ftrombus*, *trochus*, *rhombus*, and *Turbo*, which he calls the poetical name, are all fynonymous terms, and exprefs the fame fort of fhell. *Lifter*, *Fabius Columna* Aquat. & Terreftr. P. 59. p. 65.

To avoid the obfcurity which muft naturally arife from fuch confufion of words, it is proper to obferve, that *Turbo* and *ftrombus* are derivatives of the fame Greek word ϛρέφω, to turn, and therefore are, properly, but one word in fenfe, and always to be accepted as fynonymous terms, and fignifying a long and flender fhell, whofe bafe and apex are both very fmall. *Bonani* Recreat. Ment. & Occul. p. 126.

The trochus has a fmall mouth, but then its bafe is large and flattifh, and its conic figure is one of the characters of its genus. Thus is this diftinguifhed from the former; and as to the *rhombus*, when we have obferved, that, though the word properly fignifies a lozenge figure, it is ufed in fhells for the name of a cylindric kind; it will appear, from the whole, that thefe four words are not all fynonymous, but that three diftinct genera are meant by them, the firft two only being of the fame fignification.

The moft remarkable fpecies of the *Turbo* or fcrew-fhell, is that called *fcalare* by Rumphius, from its fpires running up hollow, or with a fpace between them. This is a very fcarce and valuable fhell, when large, but is often found fmall in the Adriatic.

The fpecies of the *Turbo* are fo numerous, that it is proper to arrange them under different heads.

1. Of the *Turbines* which have a long and toothlefs mouth, and a wrinkled columella, thefe are the following fpecies: 1. The nail-*Turbo*, variegated with blue fpots. 2. The awl-*Turbo*, with yellow perpendicular lines. 3. The *Turbo*, with points difpofed in circles. 4. The fpotted and lineated needle-*Turbo*. 5. The fcrew-*Turbo*, with variegated lines and fpots. 6. The whitifh reticulated and granulated *Turbo*. 7. The virgated and corded *Turbo*.

2. Of thofe *Turbines* which have dentated mouths and a wrinkled columella, we have the following fpecies: 1. The fafciated contabulated *Turbo*. 2. The *Turbo*, called the child in fwadling clothes.

3. Of thofe *Turbines* which are of a pyramidal figure, and have depreffed mouths, we have the following fpecies: 1. The telefcope-*Turbo*, with tranfverfe furrows. 2. The whitifh *Turbo*, with yellow circular lines. 3. The Chinefe pyramid or obelifk *Turbo*. 4. The rough *Turbo*, with elated rows of tubercles. 5. The granulated and lineated little tower *Turbo*.

4. Of thofe *Turbines* which have long and erect mouths, we have the following fpecies: 1. The alated borer *Turbo*. 2. The whitifh borer *Turbo*. 3. The variegated borer *Turbo*. 4. The lineated borer *Turbo*.

5. Of thofe *Turbines* which have a flat mouth, and are of a longer fhape, thefe are the following: 1. The contabulated and roftrated caterpillar-*Turbo*: this is covered with tubercles, and has blue fpots and lines. 2. The white roftrated caterpillar-*Turbo*, with many tubercles and fpires.

6. Of thofe *Turbines* which have a large oval mouth, we have the following: 1. The *Turbo* called *vitta*, with black, yellow, and red veins. 2. The claviculated and variegated agate-coloured *vitta*. 3. The whitifh *vitta*, with a variegated clavicle.

7. Of the round-mouthed *Turbines*, we have the following fpecies: 1. The hollowed wreathed *Turbo*. 2. The bone-coloured *Turbo*, with twenty wreaths, depreffed into feveral finufes. 3. The yellow and white thick-wreathed *Turbo*. 4. The *Turbo* with feventeen furrowed wreaths. 5. The fcalar *Turbo* of Rumphius, with white lines. 6. The aurited *Turbo* of Rondeletius. Hift. Nat. Eclairc. p. 271.

TURBO *Cochlea*, in natural hiftory, a name by which fome authors have called the Perfian fhell, a fpecies of *concha globofa* or *dolium*.

Many have been puzzled with this fhell, not knowing in what clafs to rank it; and Aldrovand has placed it at the end of his work, faying, that it would feem to belong to the turbinated kinds, but that it wants the *Turbo*. See the article DOLIUM.

TURBUT, in ichthyology, a name given by us to the fifh called by authors the *hippogloffus*, *paffer major*, and *paffer Britannicus*.

According to the new system of Artedi, this is a species of the pleuronectes, and it is distinguished by him by the name of the wholly smooth pleuronectes, with the eyes on the right side. See the articles HIPPOGLOSSUS and PLEURONECTES.

TURCICA *Terra*, *Turkey Earth*, in the materia medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent, and famous among them in pestilential diseases. It is sometimes brought over to us also, made up into flattish orbicular masses, of two or three drams weight, and sealed with some Turkish characters. This earth is of a somewhat lax and friable texture, yet considerably heavy, of a greyish red colour, but always redder on the surface than within; extremely soft, and naturally of a smooth surface. It breaks easily between the fingers, and melts freely in the mouth, with a considerably strong astringent taste. It adheres but slightly to the tongue, raises no effervescence with acids, and burns to a dusty yellow colour. *Hill's* Hist. of Foss. p. 15.

Many authors who have written of the materia medica, and of fossils in general, have indiscriminately called the various kinds of Lemnian earth by this name; but the true *Terra Turcica*, described by Schroder, Wormius, *&c.* is a different substance, though not sufficiently characterised by those authors to distinguish it from all the other earths.

TURCOIS (*Cycl.*)—See the Appendix.

TURDUS, in the Linnæan system of zoology, the name of a genus of birds, of the order of the passeres. The distinguishing characters of this genus are, that the tongue is jagged, and has a rim or margin round it; the bill is of a conic pointed figure, a little convex, and naked at the base. *Linnæi* Syst. Natur. p. 49.

This genus comprehends the thrush, black-bird, and starling. The distinguishing characters of this genus, according to Mr. Ray, are these: They are of a middle size between the pigeon and the lark. Their beak is moderately long and thick, and is a little bent downwards; their mouth yellow within; their tail long; and their food both vegetable substances, and insects in common. Most of these birds sing very melodiously, and may be taught to imitate the human voice in speaking. *Ray's* Ornithol. p. 137.

There are three subdistinctions of the *Turdus* kind: 1. The thrush, called by authors simply *Turdus*. 2. The merula, or black-bird, distinguished by its dark colour: And 3. The sturnus or starling, known by the breadth and flatness of its beak. We have four species of thrush in England: 1. The *Turdus visciverus major*, or missel-bird. 2. The *visciverus minor*, or song-thrush, or mavis. 3. The *Turdus pillaris*, or field-fare. And 4. The *Turdus iliacus*, or swine-pipe. See the articles MISSEL-*Bird*, MAVIS, FIELD-*Fare*, and SWINE-*Pipe*.

The two first of these build and remain the whole year with us, the others only visit us in winter. Id. ibid.

TURDUS *Chiappæ*, in zoology, the name of a bird of the West Indies, oddly and imperfectly described by Nieremberg, and said to be very dexterous at filling a pine with acorns, which are its only food, by making holes in its bark. These it fixes in so nicely, that it is not easy to get them out; and these are its store, which it eats occasionally. It is, from this practice, called also *passer faber*. *Ray's* Ornithol. p. 303.

TURDUS, in ichthyography, the name of a genus of fishes, of the class of those which have only one back-fin, the anterior rays of which are prickly; the hinder ones soft and smooth.

Of these fishes there are several species, which may properly be divided into two orders; the first, of those which are smaller and broad; the second, of those which are larger and oblong.

Of the first order are the *tinca marina*, or wrasse. See the article WRASSE. The *merula*, or *Turdus niger*. See the article MERULA. The *lepros*, and *pira pixanga*, which see. And the *Turdus viridis* or *verdone*. See the article VERDONE. *Ray's* Ichthyogr. p. 320.

Of the second order are the *pavo*. See the article PAVO. And the *Turdus viridis major*, and *Turdus fuscus maculosus*.

The *Turdus viridis major*, or great green *wrasse*, is of a fine green on its back and sides, even to the side-lines; and the lower part of the sides and belly are of a pale whitish yellow, variegated with greyish and pale blue spots. Its body is long, and not much unlike that of the pike in figure. Its back-fin is long, and has thirty-two ribs, the anterior nineteen of which are rigid and prickly, the hinder twelve soft, flexile, and ramose. The scales are large, the eyes small, and the teeth very large and strong.

The *Turdus fuscus maculosus*, or brown spotted wrasse, scarce at all differs from the other, except in colour. It is of a dusky hue on the back and sides, variegated with blue spots; and on the belly blue, with lines and spots of red. All the fins, except those of the gills, are of a red colour, spotted with blue; the tail also is of this colour, and the gill-fins are yellow. *Ray's* Ichthyogr. p. 322.

TURF (*Cycl.*)—TURF *Sweating*, an Indian method of curing diseases, which has been found to succeed very happily on many trials.

Paul Dudley, Esq; gives an account of a man of seventy-four years old in New England, who drinking cold water when very hot, had a pain settled in one side and arm, which baffled all art to remove; till after nine weeks confinement to his bed, when he was given over by every body, it was proposed to try this method of cure upon him.

An oven-full of *Turf* was ordered to be cut; the *Turfs* were of about eighteen inches square each, and were of the nature of the English *Turf* used in Gardens.

The Indian doctor, before the *Turf* was put into the oven, rubbed over their grassy side with some sort of oil or spirit, and then putting the two grass sides together, placed them in the oven. When they had been two hours there, and were well baked, he took them out, and made a bed upon the floor, the place for the head being a little raised: The old man was then taken out of bed without his shirt, but wrapped in a sheet, and being laid on the *Turf*-bed, such another parcel of the hot *Turf* was laid over him. The *Turf* was laid thickest on that side where the pain was, but none of it was put upon his breast or head.

He was then covered with a blanket to keep in the heat; and while he was in this warm bath, he was continually supplied with warm cordials to keep him from fainting, of which he was in great danger. After he had lain in this bath about three quarters of an hour, which was as long as he could bear it, he was put into a bed very well warmed, without his shirt, where he soon fell asleep, and sweated to that degree, that it run through the pillow and bed on the floor. After about two hours sweat, they rubbed and dried him, and put on his cloaths; and the old gentleman found himself much eased and refreshed. The operation was performed in the morning, and before night he walked about the house comfortably, his pain being almost all gone. The cordials were, after this, repeated, and, on the fourth day, the sweating was performed again; the day after which the old gentleman was well enough to go about his business. He lived eleven years afterwards in perfect health, and free from pain.

Great care is to be taken in this operation, that the patient do not lie too long in the *Turf*: In many cases, a quarter of an hour is found to be long enough; and the general rule is, that as soon as the patient begins to fetch his breath short or faint, he must be put to bed immediately, and the cordials must by no means be omitted; for the life of the patient is endangered without them. Philos. Trans. N°. 384. p. 129.

TURKEY, in zoology. See the article MELEAGRIS.

TURKINS, in our statutes, is used for a sky-coloured cloth. Stat. 1 R. 2. c. 8. *Blount.*

TURMERIC (*Cycl.*)—A plaster of *Turmeric*, well bruised, top and roots, is thought to be good against the bite of the rattle-snake. See Phil. Trans. N°. 479. p. 144.

TURN, (*Cycl.*) in mining, is a pit sunk in some part of a drift. If the mine be deep, there are many of these *Turns* one below another. *Houghton's* Compl. Miner, in the Explan. of the Terms.

TURN, in the manege, is a term commonly used in directing to change hands. See the article CHANGE and ENTIER.

TURN, in the sea language. See the article LAND-*Turn*.

TURNEP, *Rapa*, in botany. See the article RAPA.

It is but of late years that the farmers have brought *Turneps* into use, as an improvement of their fields. All sorts of land, when made fine either by dung and tillage, or by tillage alone, will produce *Turneps*, but not all equally.

Chalky land is too dry for them, and they are so long on it before they get into the rough leaf, that the fly often takes them, and they are destroyed. Sometimes, however, they succeed well in this sort of land, though rarely. Charlock is a weed very apt to infest *Turnep*-lands, and when the *Turneps* and this are both young, they are so alike, that there have been instances of the people sent to weed, mistaking one for the other, and cutting up all the *Turneps*, and leaving all the charlock.

Sandy and gravelly land are found to be the best for *Turneps*, because these soils are most easily pulverized, and have a warmth that makes the *Turneps* grow much faster than they would in a colder ground. By this means they are preserved from the danger of the fly, which only infests them while not yet grown into the rough leaf; and this sort of soil, when well tilled and hoed, never wants moisture even in the hottest weather. The dews reach as deep as the plough or hoe penetrates, which is six or eight inches; and the sun's heat with us is never so great as to exhale it wholly from that depth. *Tull's* Horsehoing Husbandry, p. 44.

When *Turneps* are sowed by hand, and hoed by hand-hoers, the plants grow too close, and the operation is never half performed, the workers usually leaving one half of the land unhoed, and covering it with the earth they cut up from the other parts; so that the weeds there being only buried an inch or two deep, grow more vigorously than before. The true method is to sow them by the drill, and horse-hoe them afterwards. By this means the plants are kept at a proper distance, and the earth opened between them. The effect of this, upon a fair trial, has been proved to be, that the drilled *Turneps*, when gathered, have been twice the quantity of the sown ones, upon an equal quantity of ground, though the handhoing of the latter had cost at the rate of ten shillings an acre.

In the method of drilling, they are sure to come up quickly, because in every row half the seed is planted at four inches deep,

deep, from which, or even a greater depth, this feed will come up well; and the other half is planted exactly over that at half an inch depth, falling in upon the earth that has covered the first half. Thus planted, if the succeeding weather be ever so dry, the deep half of the feed will certainly come up; and if it chance to rain much soon after the sowing, then the shallow half will be up first. The plants may also be made to come up at four successive times, by mixing the feed half new and half old, for the new will be sure to come up two days, or thereabout, before the old.

Turnep-feed should always be sown in this manner, in order to its escaping the danger of the fly, which otherwise often destroys whole fields of the young plants; but these four chances secure it; for though one coming up suffers, another escapes it, being often found, that the feed sown over-night has been ruined by the fly, while that sown the next morning has wholly escaped.

When the fly is found likely to devour them, they may be horse-hoed; this will bury the greatest part of those animals; or they may be drilled in another row, without new ploughing the land. This fly feeds only on the two first or feed-leaves of the *Turnep*, which are very sweet; the following leaves are rough, and do not suit its taste; so that if the plants escape being eaten up while in the feed-leaves, they escape entirely.

The most infallible of all methods of preventing the mischief from this fly, is to make the ground very fine, and then roll it with a heavy roller across the ridges, after it is drilled; this method closes up the cavities in the earth, and prevents the fly's entrance or exit to lay the eggs, hatch, or bring forth the young ones, to prey upon the *Turneps*. This rolling always disappoints the fly; but it sometimes also disappoints the owner, if he has sown the crop by hand in a scattering manner. These feeds, lying near the surface, are injured, and the ground, hardened by the rolling, will not let them grow well, but they become yellow, dwindle, and come to no perfection, unless they have a thorough hoing, as soon as the rough leaves appear. The drilled *Turneps*, being in single rows, with six-foot intervals, may be rolled without danger; for, be the ground ever so hard, the hand-hoe will easily single them out to a proper distance, at the expence of six-pence an acre, or less, if not in harvest, and the horse-hoe will plough in those wide intervals to great advantage, whether the season be wet or dry. Three or four ounces of feed in the drill way, answers for as much land as three or four pounds in the hand-sowing; and there is this other advantage, that the plants, all standing in rows, will be easily distinguished, and properly singled out to their due distances, while very young; which is a thing of great advantage, as they thrive much the better for being early separated from their useless neighbours. The six-foot ridges, whereon *Turneps* are drilled in single rows, may be left higher than for double-rowed crops; because there will be more earth in the intervals, as the single rows take up less.

There is no prefixed time for planting *Turneps*, because the nature of the soil must be consulted; some land will bring them as forward when planted in August, as other land will when planted in May; but the usual time is the middle between these, that is, about Midsummer. It is a practicable scheme, when *Turneps* are planted in rows, with these large intervals, to sow wheat between. In the latter end of September, when the *Turneps* are full grown, a ridge is to be ploughed in the middle of each of the intervals, taking the earth to the ridge in such quantity, as only to leave enough with the *Turneps* to keep them alive; wheat is to be drilled on this ridge: Toward spring the *Turneps* are, in this case, to be pulled up, and carried off the ground. The wheat being now left alone, the land is to be well horse-hoed in the intervals. In Spring the wheat may be sown in treble rows, and will afford a good crop. If the *Turneps* stand so thick in these single rows as to touch one another, when half grown, provided the intervals between the rows be well horse-hoed, they will yet attain to their full bigness; and they are often found to have thrust one another out of shape, and become oval instead of round.

It is best to give the first hoing alternately; that is, to hoe only every other interval; this keeps them from being stunted, and it proves better thus to give them their food at twice, than to do it all at once. Id. Ibid.

In horse-hoing it is not well to come nearer than within three inches of the sides of the rows; but where the *Turneps* are planted in double rows, as soon as their roots are grown as large as a finger, the prong-hoe is to be used between the plants; and even in that little space of three inches, left by the horse-hoe, when they are in single rows. Four of the alternate hoings in the intervals are found, on trial, to be equal in use to four whole hoings, though they are done at half the expence; for this half-hoing furnishes the *Turneps* with as much nourishment as they require, and 'tis in vain to give more.

Dry weather is very injurious to *Turneps*, when sown in the common way, and only hand-hoed; because the hoe, in this case, does not penetrate deep enough to keep the ground moist; but in horse-hoing the earth is cut so deep, that it is always kept moist, and a dry season does the crop no hurt. Dung and tillage will, in all cases, do their business quicker than tillage alone. On this principle, *Turneps* have more occasion for dung than any other plants, because they have less time to grow.

Twelve pound weight may be esteemed the middle size for the great *Turneps*, and they sometimes grow to sixteen or nineteen pound weight. The farmers great interest in them is their size; and it seems evident that every *Turnep* in a field may be made to grow to its full standard, or the largest size that nature has allotted it, provided it be properly managed, and nourishment supplied in a due manner. The greatest inconvenience that attends *Turnep* husbandry, is, that when they are to be eaten off in the Spring, which is their chief use, they do not leave time for bringing the land in tilth for barley; and the loss of a crop of this is more than the gain by the *Turneps*; but this is wholly remedied by the horse-hoing husbandry, in which the land may be almost as well tilled before the *Turneps* are eaten off, as afterwards.

If the *Turneps* be sown in June, the most experienced farmers will have only thirty plants left to a square perch in the hand-hoing, finding that if more are left, they starve one another, and the crop will be worse; but in drilling the rows at six foot intervals, there will be at least sixty left to the perch, and these will thrive well, if the soil be rich, and well broken.

Sixty *Turneps* to a square perch, at five pound each, which is but a third part of the size of sheep-*Turneps* at their full growth, will make a crop of above eighty quarters to an acre.

When *Turneps* are planted late upon poor ground, they may be left more numerous; because they will not have the advantage of heat for the hoing, that would make them grow larger, when set out at greater distances.

The greatest *Turnep* improvement of the farmer is for his cattle in winter; one acre of *Turneps*, at this season, will maintain more than fifty of meadow or pasture land. Most cattle will eat *Turneps*, and they breed milk better than any other food whatever. Sheep always refuse them at first, and, unless they have eaten them while lambs, they will be ready to starve before they will touch them; but as soon as hunger compels them to fall to, they are soon fattened by them. Lambs of three weeks old will eat them, scooping them very prettily, while those of a year old, which are called *tegs*, will not touch them of three or four days, till almost famished.

In some places, the greatest use of *Turneps*, except for fattening oxen and sheep, is for ews and lambs in the spring, when natural grass is not grown up on poor grounds. Sometimes the farmers are obliged to keep their ews and lambs upon them till April, though they were run up to feed in the mean time. Id. Ibid.

There are three manners of spending *Turneps* with sheep. See the article Sheep.

The white and purple-rooted *Turnep* are the two kinds raised for the use of the table in England. They thrive best in a dry sandy soil, that is not too rich; if the ground be too rich, they are apt to grow sticky; but they are always the best tasted when produced on fresh, not on worn-out lands. The common time of sowing them is from the beginning of July to the middle of August; but the gardeners about London sow them every month from March to August, that they may have a constant supply; those sown early always succeed best when sown on a moister soil than the others; for when on a dry one, they are subject to great damages, and are often almost wholly destroyed by a fly.

Turneps must always be sown in an open place, for if they stand near hedges, or under shelter, they run up into tall stalks, and do not grow at the root. *Miller*'s Gardener's Dict.

TURNESOL, a plant of considerable use by the colour prepared from it, and known under its name. The root of these plants is long and white; the leaves resemble in shape those of the xanthium, or lesser burdock; they grow on long pedicles, and are of a whitish or ash-coloured green. The flowers form a sort of cluster, and grow out of the alæ of the leaves; they are of two kinds on the same plant, barren and fruitful, or, as botanists express it, male and female.

The barren, or male flowers, occupy the top of every cluster, and are placed each in a cup, divided into five segments, and themselves consist each of five small yellowish leaves, with a bundle of stamina in the middle. The female, or fruitful flowers, are placed at the bottom of the cluster, and are surrounded each by a cup, divided into ten segments; they are composed of five stamina, which surround a pistil which is furnished with three forked filaments. This pistil, which is fixed in the bottom of the cup, finally becomes a round fruit, of a rough surface, and green colour, its protuberances only appearing a little whitish. This fruit is divided into three cells, and each of these contains one round feed. The whole fruit is attached to the cup by a very long pedicle, so that when the flowers are withered, and it has arrived at its maturity, it is found hanging from the alæ of the leaves, and seems to have been produced without any flower; and this is what has led some writers into the error of imagining, that the flowers and fruit of this plant grow on different stalks.

Some have translated *Turnesol* by the English word *sun-flower*, which has led many to suppose that the great yellow sun-flower

flower which we keep in gardens, was the plant that afforded the *Turnesol* colour: But this is a mistake; and it is to be observed, that the true *Turnesol* plant here described, is very common in the fields of France and Germany, but does not grow wild with us in England.

The juice of the berries of the *Turnesol* rubbed upon paper or cloth, at the first appears of a fresh lovely green, but presently changes into a kind of bluish purple. The same cloth, afterwards wet in water, and wrung out, will turn the water into a claret-colour: And it is to be observed, that these are the rags of cloth usually called *Turnesol* in the druggists shops. *Boyl*'s Works abr. vol. 2. p. 79.

The lixivium of this plant in lime-water and urine, or in the volatile spirit of wine, turns marble blue. See the article *Colouring of* MARBLE.

TURNESOL, in botany, &c. See the article HELIOTROPIUM.

TURNING (*Cycl.*)—TURNING-*Evil*, in cattle, a disease that causes them frequently to turn round in the same place. It is also called the *sturdy*.

The common remedy, recommended by Mr. Markham, is to throw the beast down, and bind him; then to open his skull, and take out a little bladder, filled with water and blood, which usually lies near the membrane of the brain, and then gradually heal the wound. *Boyle*'s Works abr. vol. 1. p. 87.

TURNO *Vicecomitum*, a writ that lies for those that are called to the *sheriff's turn*, out of their own hundred. Reg. orig. 173. *Blount*, *Cowel.*

TURNSTONE, in zoology, the English name of a bird called by authors the *morinellus marinus*, or sea-dotterel.

It is a little larger than the blackbird; its head moderately thick, and its body of a longish shape; its beak a finger's breadth long, thick at the base, and sharp at the point; and its head, neck, shoulders, wings, and the upper part of its breast, are of a brownish colour; its throat and belly are snow-white; the middle of its back has a very large white blotch; and its rump is variegated by a broad transverse streak of black; its legs are short, and of a reddish yellow or orange colour. *Ray*'s Ornithol. p. 231.

TURONILLA, in zoology, a name given by some authors to the common little prickly fish called the *stickleback* or *barnsticle*, and more usually known among authors by the names *pugnitius* and *aculeatus pisciculus*. *Rondelet.* de Aquat. p. 9. See the article PUGNITIUS.

TURPENTINE (*Cycl.*)—In the distilling of *Turpentine* and other balsams by a gentle heat, it has been observed, that there arises first an acid spirit, that will mix with water; which spirit, except the fire be very gentle, is lost. This grateful acid spirit, that first comes over, is, as a learned chemist and physician informs us, highly refrigeratory, diuretic, sudorific, balsamic, or preservative from putrefaction, excellent in nephritic cases, and for quenching thirst; all which virtues the bishop of Cloyne thinks contained in the cold infusion of tar, which draws forth only its fine flower, or quintessence, or the native vegetable spirit, together with a little volatile oil. See the article TAR-*Water*.

Turpentine is a fine resin, whereof there are four kinds in use; the *Turpentine* of Chios or Cyprus, which flows from the *Turpentine*-tree; the Venice *Turpentine*, which is got by piercing the larch-tree; the Strasburgh *Turpentine*, which Mr. Ray informs us is procured from the knots of the silver fir; it is fragrant, and grows yellow with age. The fourth and last kind is common *Turpentine*, which is neither so transparent nor so liquid as the former; and this Mr. Ray takes to flow from the mountain pine. All these *Turpentines* are useful in the same intention. Theophrastus says, the best resin or *Turpentine* is got from the terebinthus growing in Syria, and some of the Greek islands. The next best is that from the silver fir and pitch-pine.

Turpentine may be of use to preserve the bodies of insects. Mr. Boyle [a] took clear Venice *Turpentine*, and evaporating to two thirds, obtained a reddish transparent gum, clear of bubbles, easily soluble by heat, and as easily rendered brittle by cold. Having first pulverized it, he melted it for use, with a gentle heat, and dipped the body to be preserved several times therein, till it acquired a case of due thickness.—[[a] Works abr. vol. 1. p. 29, 30.]

Oil of TURPENTINE. The *oil of Turpentine*, taken in too large a dose, hath often very bad consequences, such as a strangury, bloody urine, and its total suppression, with a fever, violent thirst, and vomiting.

In the Medic. Eff. Edinb. vol. 2. art. 5. we have an account of such symptoms produced by the taking two drams of this oil in warm ale. The patient was cured by a warm bath, and drinking plentifully of Fuller's *emulsio Arabica*.

TURPENTINE-*Tree*. This tree, besides its proper fruit which succeeds the flowers in the usual way, is remarkable for producing what authors of little curiosity have named another fruit, called its *horn*. This horn is a membranous production, of the length and thickness of a man's finger; and what surprized those authors who esteemed it a sort of pod, was to find that it produced not seeds, but living animals, which they called flies.

The true history of this horn is, that it grows from the surface of the leaves, not from the stalks in the manner of fruit; and is no natural production of the tree, but a mere accidental thing, occasioned by the wound of an insect on the leaf. There are a genus of small animals called *pucerons*, some of which have wings, others not, and which we see very frequently in vast clusters on the leaves and stalks of several plants. A certain species of these animals is peculiarly fond of the juices of the *Turpentine*-tree, and always takes its abode upon its leaves. The female of this animal, soon after it is produced from its parent, makes its way under the covering or upper membrane of the leaf, and there lives secure till it produces its young. These, as soon as they are brought forth, begin to suck, and fixing usually upon the sides and top of the cavity in which they are placed, they occasion a great derivation of juices to that part of the membrane of the leaf which covers them; and the consequence of this is, that it rises up from the leaf, and begins to grow into a long body; the formation of this afterwards is the same with that of all other galls, and is owing to the same cause, a wrong derivation of juices. This gall-horn, or bladder, which ever it be called, continues to grow in length, till it burst somewhere at the sides, and then the winged and creeping brood appear. This, though esteemed so great a wonder by many, is far from being peculiar to this tree, for our common elm affords galls much of the same kind. See the article PUCERON.

TURPENTINE-*Tree*, in botany. See the article TEREBINTHUS.

TURREBA, the *Earth-Apple*, in natural history, a name given by the people of Guinea, and some other parts of Africa, to a very fine kind of truffle, which they find in great plenty in their barren desarts, four or five inches under the sand.

TURRITIS, *Tower-Mustard*, in botany, a genus of plants which have four-leaved cruciform flowers, succeeded by long pods, containing a number of seeds. The plants of this genus differ from the hesperis, in that they have flat pods; from the leucoium, in that the seeds are not marginated; and from the cabbage, both in the flatness of the pods, and in the whole appearance of the plant.

The species of *Turritis*, enumerated by Mr. Tournefort, are these: 1. The common or larger *Tower-Mustard*. 2. The smaller *Tower-Mustard*. 3. The branched *Turritis*. 4. The leucoium-leaved *Turritis*. 5. The cut-leaved alpine *Turritis*. 6. The *Turritis* with the lower leaves like those of succory, the others perfoliate. And 7. The purple spring *Turritis*. *Tourn.* Inst. p. 223.

TURSIO, in zoology, a name by which Bellonius, Scaliger, and several others, have called the *phocæna* or *porpesse*, distinctively from the dolphin, with which it is confounded by the vulgar. *Willughby*'s Hist. Pisc. p. 31. See the articles DELPHINUS and PHOCÆNA.

TURTLE, in zoology. See the article TURTUR.

TURTLE, in ichthyology, the name by which we commonly call the great sea tortoise. See the article TESTUDO.

TURTUR, in zoology, the *Turtle-Dove*, a very beautiful little bird of the pigeon kind. The head, neck, and back, are of the bluish-grey colour of the common pigeon, with some mixture of a reddish brown near the rump, and at the bottom of the neck. Its breast and belly are white; but its throat of a fine bright purple; and the sides of the neck are variegated with a sort of ringlet of beautiful white feathers, with black bases. It feeds on hempseed, and other vegetable matters. *Willughby*'s Hist. Avium. p. 134.

TURTUR, in ichthyology, a name given by Paulus Jovius, and some other writers, to the fish called the *pastinacha marina*. It is the *tragon* and *trygon* of the old writers, and is a species of the rayfish distinguished by Artedi by the name of the smooth-bodied ray, with no fin in the tail, but with a bony spine in it, serrated on one side.

TURTUR, the *Turtle-Shell*, in natural history, the name given by the collectors of shells to a very beautiful species of murex, common in the cabinets, but not found any where on the shores. This is owing to its having greatly altered its appearance in the polishing; for it is no other than the white and brown-mouthed murex, which is common in its rough state, with its outer coat taken off. See the article MUREX.

TUSHES, in the manege, are the fore-teeth of a horse, seated beyond the corner teeth, upon the bars; where they shoot forth on each side of the jaws, two above, and two below, about the age of three, three and a half, and sometimes four: and no milk or foal-teeth ever come up in the place where they grow. See the article TEETH.

TUSSILAGO, *Coltsfoot*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the radiated kind. The disk is composed of floscules; and the outer circle of semi-floscules; these stand upon the embryo seeds, and are all contained in a scaly cup. These embryos finally become seeds winged with down, and adhering to the thalamus of the flower. To this it is to be added, that the flowers appear before the leaves. *Tourn.* Inst. p. 487.

There is no other known species of this plant but the common *Coltsfoot*. See Tab. 1. of Botany, Class 14.

The common *coltsfoot* ftands generally recommended as a very great medicine in coughs, and all diforders of the breaft and lungs. It is alfo fometimes ufed externally in inflammations.

TUSSIS, the *Cough*. Medical writers define a *Cough* to be a difcuffory and elifory motion of the breaft, by means of which nature attempts to throw off fomewhat that is offenfive to her.

Phyficians diftinguifh *Coughs* into the idiopatic and the fymptomatic; the firft is truly pectoral; the other only affects the breaft, by means of the confent of parts. Of the fymptomatic, or, as fome exprefs themfelves, the confenfual *Coughs*, fome have a catarrhal difpofition, and have a coryza for their origin or attendant, or, more ftrictly fpeaking, a gravedo; fometimes a bronchus, hoarfenefs, and inflammation of the tonfils; others are called hypochondriacal, which fometimes arife from diforders of the ftomach, and are therefore called dry ftomachic coughs; and fometimes from fchirrofities of the liver, whence they are common to people in cachexies, and in hectics and dropfies.

A *Cough*, which rifes from internal caufes, is to be carefully diftinguifhed from one that rifes from external. The dry and the moift *Cough*, that is, thofe in which matter is fpit up, and thofe in which nothing is evacuated, differ alfo greatly, as well in regard to their fymptoms, as to the perfons they attack. The dry *Cough* is always more tedious in cure than the moift, and more eafily returns. The ftomachic *Cough*, which is owing to confent of parts, is known by the quantity and thicknefs of the matter that is fpit up, which is always moft frequent after meals, and gives a tendency toward a reaching to vomit. This moift ftomachic *Cough* differs in this manner, in all particulars, from the dry cough of the fame name and origin with it, as mentioned before.

The hypochondriac *Cough* is abundantly diftinguifhed from the other kinds, by its drynefs, and by its vehement violence, for it always leaves a hoarfenefs behind it; this always is moft violent after eating, and after drinking large draughts of cold liquors, or afcending fteep places. As alfo by its bearing very well a cold and humid air, and not being exafperated by it, as the pectoral *Coughs* are; and finally, by a fenfation of a concuffion of the diaphragm, when the effects in coughing are violent. *Junker*'s Confp. Med. p. 514.

The common habitual dry *Cough* is diftinguifhed from the other kinds by its remarkable drynefs; and the common moift habitual *Cough* by its abundant quantity of matter difcharged, and by its appearing pulpy and greenifh, and not fanious, or ftreaked with blood, and continuing in the fame degree ufually for a confiderable time. In this habitual *Cough* there is no wafting of the flefh, nor is there that violent exacerbation on the taking of opiates, which is always found in the phthifical *Coughs*, to which all opiates feem the greateft enemies. This *Cough* alfo always receives great benefit from purging medicines, but the phthifical *Cough* none at all: But both thefe differ greatly, according to the age and temperament of the body of the perfon afflicted with them.

Perfons fubject to Coughs. The fimple idiopathic *Cough*, arifing from internal caufes, whether it be of the moift or dry kind, is almoft peculiar to young people, and thofe of plethoric habits. The catarrhal fymptomatic *Cough*, which arifes from external accidents, is common to perfons of all ftates and ages; but is more frequent among old men than among others. The perfons moft fubject to the common dry *Cough* are young people of a florid conftitution and dry habit of body; and men of the middle or more advanced ages are fometimes alfo afflicted with it, from fuppreffions of the hæmorrhoidal difcharges, or from omiffions of habitual bleedings; as are alfo people who are badly conformed, gibbofe or crooked, and fuch as are afflicted with the evil, or have calculi in the bronchia, or nodes of a fchirrous nature in the lungs; and finally, fuch as have been ill-treated in the fmall-pox, or have had the itch, or any other violent cutaneous eruption ftruck in upon them. People moft fubject to a common moift *Cough* are thofe of a phlegmatic habit, fuch as are apt to cool their neck and breaft in autumn in damp cold air in evenings; fuch as have omitted their habitual bleedings, and fuch as have drank too freely of fpirituous liquors, or taken too much of acids. The idiopathic pectoral *Cough* arifes from a congeftion of humours in the breaft; and the hypochondriac *Cough* is either owing to a fault in the ftomach, or to a fchirrofity in the liver. *Junker*'s Confp. Med. p. 515.

Prognoftics in Coughs. The fimple idiopathic pectoral *Cough* very frequently goes off of itfelf, without the affiftance of medicines, or with no farther affiftance to nature than bleeding, judicioufly managed; but though thus gentle while recent, yet when it is become habitual, and fixed upon a perfon, it is very obftinate; and though at firft it is far from a confumptive *Cough*, yet there is no certainty but that it may, at fome time or other, occafion ulcerations in the lungs. A dry *Cough* in young people is much to be feared, when of long ftanding, for it not unfrequently degenerates into a fpitting of blood, or into a confumption: This kind fometimes alfo changes into what authors call the *ferine Cough*, which is fo violent, that perfons afflicted with it are fcarce able to recover themfelves after a fit of it. In general, any *Cough* that feizes a perfon in the Spring, is much eafier cured than one that attacks in Autumn. Periodic *Coughs*, that have been long ufed to return upon people at certain times, are always to be fufpected of danger, if they leave them fuddenly, and no natural or artificial evacuation is made in their place; for they too often bring on faults in digeftion, and fometimes fuffocative catarrhs, and paralytic diforders: A moift habitual *Cough*, when it fuddenly changes into a dry one, is alfo a bad prognoftic. A violent dry hypochondriac *Cough*, that frequently remits and recurs again, and is ufually worft in the night, gives great reafon to fufpect a fchirrofity in the liver; and the more regularly it returns at ftated times, the more certain is the defect of this or fome other of the vifcera; fo that the prognoftic is very fatal and very certain from it. *Junker*'s Confp. Med. p. 518.

Method of Cure. In cafe of a moift pectoral *Cough*, it is proper firft to give a purge, not violent, but yet moderately ftrong, to derive the matter from the breaft; and the catarrhal matter muft then be prepared for evacuation; when it is fimply mucous, the common refolvent and difcutient catarrhal medicines are to be depended upon; fuch are decoctions of the roots of pimpernel and iris, with the leaves of hyffop, horehound, fcabious, and fpeedwell; with thefe are to be given the attenuant gums, as ammoniacum, benjamin, and fagapenum, with the warm carminative feeds. When the matter is too tough and vifcous, the bufinefs then is, on the contrary, to incraffate and reduce it to a foft pulpofe body. This is effected by liquorice-root or juice, with gum arabic, figs, ftarch, together with all the fulphureous medicines. If, on the contrary, the matter is thin and acrimonious, and irritates violently, then the cure is to be effected by fuch things as obtund and fweeten it; of this kind are emulfions of almonds, and the cold feeds, with barley-water, water-gruel, the mucilages of quince, and fleawort feeds, and the like; and to thefe are to be added occafionally, fperma ceti, and oil of fweet almonds: When the *Cough* is habitual, laxatives are to be given after thefe, or in the intermediate times, during the taking them; and if the *Cough* returns, when the matter of it is no longer the caufe, it is to be quieted by gentle opiates, fuch as the ftorax pill; and finally, corroborants are to be given to reftore the due tone of the lungs.

In the dry *Cough* the gentleft purges only can properly have place, and nothing is fo proper as to begin with fmall dofes of rhubarb; after this, to difcufs the ftagnating blood about the breaft, decoctions of the pectoral herbs are to be taken in large quantities, fuch are coltsfoot, fcabious, maiden-hair, and the like. While the patient is taking thefe, he fhould frequently wafh his feet in warm water; and finally, the cure is to be compleated by fuch corroborants as reftore the due tone of the lungs; of this kind, Stahl's tonico-nervine mixture is a very excellent medicine.

In the hypochondriacal *Cough*, as there is generally a fault in the liver, the *Cough* can never be cured, unlefs that defect can be removed. The *Cough* is therefore to be judged, in this cafe, only a fymptom of the difeafe, and the method of treatment muft be the fame as in the infarctions of the liver. See the article HEPATIS *Infarctus*.

When this obftruction is removed, the *Cough*, occafioned by it, goes off of itfelf. In cafes where the hypochondriac *Cough* depends on a fault in the ftomach, the firft confideration to be had, is, whether it be dry or moift; when it is dry, we may conclude that the fault is not fo much in the ftomach, as in the parts about it; and hence the motion of the congeftions of blood toward the vena porta are to be regarded.

The moift ftomachic *Cough* always brings the breaft into confent, and is hence often called a *ftomachico-pectoral Cough*; for the mucous matter which lies in the fauces, and is daily evacuated rather by hawking than coughing, probably afcends up the cefophagus, and caufes a flight *Cough* in the day-time; but in the night, when that excretion ceafes, it is eafy for fome little humidity to flip down the afpera arteria; and this will be again thrown up by coughing in the morning. In the cure of this, there muft be firft given fome gentle purges; after thefe, fuch medicines as refolve vifcofities in their firft formation; in which intention the roots of elecampane and pimpernel, with that of florentine orrice, are of great effect; and in the food it will be proper to eat large quantities of ginger, pepper, and the other fpices; and at night, going to bed, drink a fmall glafs of brandy. When the difeafe begins to mitigate, the effence of amber is a medicine that will do the greateft fervice.

Bleedings in *Coughs* in general, when the conftitution is plethoric, and they are done at proper times, are of great fervice in breaking the force of the difeafe; nay, in cafes of a true phthifis, bleeding often greatly retards, and keeps off the bad fymptoms. It is to be obferved, however, in all thefe cafes, that, when the conftitution will bear it, the quantity taken away fhould be larger, for otherwife they only invite a larger afflux of blood to the breaft, and fo increafe inftead of mitigating the force of the difeafe.

Bleeding is always more neceffary in a dry *Cough* than in a moift one, unlefs the fuppreffion of fome natural hæmorrhage, or the omiffion of the habitual bleedings, have been the occafion of it. Bleeding is alfo the more neceffary in *Coughs*, as they

they return at times with renewed violence, and hurt the breast and lungs; and, in this case also, if cupping has been frequently used, and lately omitted, it must be had recourse to again. Purging medicines have the most speedy effects in moist *Coughs*, and indeed in dry ones they are not always safe, or, at the most, very gentle purgations alone are proper in this last case, where there is not a load of attending matter to be evacuated, as in the first. Sweating medicines are by some prescribed in *Coughs*; but they have no proper place in any judicious regimen for these cases, unless after the *Cough* is cured, and the matter carried off, when they may perhaps be of some service to compleat the restoration of the constitution to its pristine state, by an equal distribution of the humours through the whole body. In simple *Coughs* there is occasion for very few medicines, and, in general, inciding things, which dispose the matter to an easy evacuation, with gentle laxatives, do the whole business.

The commotions occasioned by humid *Coughs* are never extremely violent, nor of any great danger, and therefore it is not necessary to be at any great pains to allay them by opiates; but these are very successfully given in cases where the emotions are greatly too violent for the quantity of matter, or where they continue after the matter is carried off and evacuated. In this case the storax pill is of great service. *Junker*'s Consp. Med. p. 520.

TUTSAN, in botany, &c. See the article ANDROSÆMUM.

TUTTI, in the Italian music, is used to signify that all the parts are to play together, or to make a full concert.

In this sense *Tutti* stands opposed to *soli* or *solo*. See the article SOLO.

It is often found expressed by *omnes*, *ripieno*, *da capella*, *choro*, &c.

TUTULUS, among the Romans, a manner of dressing the hair, by gathering it up on the forehead into the form of a tower. *Pitisc.* in voc.

TUTULUS likewise signified a woollen cap with a high top.

TUTTY, *Cadmia fornacum* (*Cycl.*)—Dioscorides and Pliny differ considerably in their accounts of this substance, though they and all other authors agree in the material part of its history, *viz.* That it is a recrement of metals collected in the furnaces where they are melted.

Pliny mentions a kind called *capnitis*, or the *smoak Cadmia*. This is not mentioned by Dioscorides. This *Cadmia capnitis* was the finest and most subtile of all the kinds; it was found at the mouths of the furnaces, where the flames burst out on stirring up the fires.

The botryoide *Cadmia* was esteemed a very good kind. This was, according to Pliny, of two colours, grey and red. The red, he tells us, was very much the better kind. Dioscorides mentions no such thing as a red *Cadmia*, but only says, that the grey botryoide kind, when broken, appeared of a rusty colour, and spotted within. This is the worst kind, according to Pliny.

Dioscorides no where mentions his red kind, but he names after this a blue sort, which was greatly preferable, and which was white within.

As Pliny does not mention this blue *Cadmia*, nor Dioscorides the red, it is probable that they are the same thing, especially as both agree in their being the most excellent kinds. The Greeks had a way of expressing all things that were blue by the word *cyanizusa*, or resembling the *cyanus* in colour. This word κυανίζουσα seems to have been the word that Pliny mistook in his description taken from this or some other Greek author, for the other or better kind of botryoide *Cadmia*, and reading φοινίσσουσα for κυανίζουσα, translated it red instead of blue. We have so many inaccuracies of this kind in Pliny, that it is much better to reconcile his account of the cadmia thus, than to suppose he was acquainted with a species of that substance, which no body else ever knew.

TWAITE, in our old writers, a wood grubbed up and converted into arable land. Co. Litt. 4. *Blount.*

TWENTY *four Men*: Men chosen every half year to redress the grievances of the mines and miners; but every man generally serves his year when chosen. *Houghton*'s compl. Miner. in the Explan. of the Terms.

TWISTED, (*Cycl.*) in the manege, called in French *Bistourné*, is used for a horse reduced to the same state of impotency with a gelding, by the violent wringing or *twisting* of his testicles twice about; which dries them up, and deprives them of nourishment.

TYGER, or TIGER, *Tigris*, in zoology. See the article TIGRIS.

TYING *Course*, among brick-makers. See the article BRICK.

TYLOS, in zoology, a name by which many authors have called the *turdus iliacus*, or red-wing. See the article RED-*Wing*.

TYMPANA, τύμπανα, among the Athenians, a capital punishment, wherein the criminal being affixed to a pole, was beaten to death with cudgels. *Potter.* Archæol. Græc. l. 1. c. 25. T. 1. p. 134.

TYMPANOTRIBA, among the antients, a designation given to an effeminate person, who could do nothing but play on the tympanum. *Pitisc.* in voc.

TYMPANUM (*Cycl.*)—The *Tympanum*, or barrel of the ear, is a cavity irregularly semicircular, the bottom of it being turned inward, and the mouth joined to the circular groove of the external auditory passage. It has both eminences and cavities observable in it. The remarkable eminences are three in number, a large tuberosity lying in the very bottom of the barrel, a little toward the back part, and a small irregular pyramid, situated a little above the tuberosity, and a little more backward; the apex of it is perforated by a small hole, and on one side of the basis, two small bony filaments are often found in a parallel situation. They are seldom found to be wanting, on a careful investigation, though their tender structure exposes them to be very often broken. In the third eminence is a cavity shaped like the mouth of a spoon, situated at the upper, and a little toward the anterior part of the bottom of the *Tympanum*. This cavity is part of a half canal, and at a very small distance from its point, is a little bony ridge, which goes from one edge of it to the other, but is seldom found entire. The principal cavities are the openings of the cells of the mastoide sinuosities, the opening of the eustachian tube, the bony half canal, the fenestra ovalis and rotunda; and to these may be added the small hole in the pyramid. The opening of the mastoide cells is at the posterior and upper part of the edge of the barrel; the cells themselves, which end there, are dug in the substance of the mastoide process, being very irregular and full of windings and turnings. The opening of the eustachian tube is at the anterior, and a little toward the upper part of the edge of the barrel. This tube, which in France is usually termed the aqueduct, runs from the *Tympanum* toward the posterior openings of the nasal fossæ and arch of the palate. The bony portion of it, the only part spoken of here, is dug in the apophysis petrosa along the duct of the carotide apophysis; and when it leaves that, it is lengthened out by the spinal apophysis of the os sphenoides. These too cavities, the mastoide cells, and the eustachian tube, are, in some measure, prolongations of the *Tympanum*, one anterior, the other posterior. The bony half canal, of which the cavity, like the mouth of the spoon, is the extremity, lies immediately above the eustachian tube, toward the upper side of the apophysis petrosa, or rather in the very substance of that upper side, and in a natural state a small muscle is lodged in it. *Winslow*'s Anatomy, p. 47.

TYMPANY (*Cycl.*)—This disease has been generally accounted, both by the antients and moderns, a species of dropsy, but very improperly; for though it is often productive of, or complicated with an ascites, yet it is in itself a perfectly distinct disease, and accompanied with no extravasation of water in the abdomen, persons who have died of it having been found, on opening the body, with the abdomen as dry as in a state of health; but the stomach has been found, in some, greatly distended with flatulencies, and containing a viscid humour, though in no great quantity. The intestines are also usually found distended, and, as it were pellucid, and, on being pricked, they collapse, without the appearance of any water. And, in some cases, on opening the abdomen, the whole swelling has subsided, on the exclusion of a gross flatulence which had distended it. The intestines have, in some subjects, been found distended to the bigness of a man's thigh, in some parts, and in others lower down, so contorted and twisted together, that there could be no passage either for the wind or the excrements. It is not uncommon also, on dissection, to find great numbers of worms, of the common long kind, in the intestines.

A *Tympany*, without a dropsy, is most incident to women after labour, when the lochia have been suppressed by colds or otherwise, or discharged in too small quantities; a bad regimen during the lying in, and the omitting to swathe the belly properly down, has also often a bad effect this way. In cases of this kind, women find soon afterwards the abdomen inflated, with a considerable uneasiness, a difficulty of breathing, costiveness, and an unaccountable anxiety. These are the breeding symptoms of the approaching *Tympany*; and the same often happens after unskilful treatment in abortions, and after the leaving a part of the lochia behind, or the injuring the uterus in delivery.

Children are also subject to *Tympanies*, when violently afflicted with worms, and sometimes after the measles and small-pox; and if due care is not taken of these cases, at their beginning, the superior parts soon become extenuated, and the patients die. Extream voracity of children also, and their eating great quantities of food at a time, when the stomach is weak, sometimes brings on this disorder.

The *Tympany* is justly accounted one of the more dangerous kinds of diseases, since the persons afflicted with it much oftener die than recover. When it is accompanied with a dropsy, it is scarce ever cured; and a simple *Tympany* in women and children, if neglected at first, degenerates into a chronic disorder, and hardly admits of a cure. Some, indeed, have gone so far as to say, they never knew a patient, afflicted with a *Tympany*, recover; but this seems too rash a judgment. That distention of the abdomen, which is properly called a flatulent colic, is by some accounted a species of *Tympany*; but this is not naturally dangerous, and is easily cured, except

 where

when it is attended with fpafms of the vifcera, in which cafe the medicines, given to reftore the due tone of the inteftines, are by no means proper in regard to the fpafms.

In curing flatulencies of the ftomach and inteftines, the proper method is to promote the difcharge of the vapours by the anus, and to attenuate and carry off by ftool the vifcid matter which is the occafion of them. To this purpofe difcutient and evacuating glyfters are very ferviceable: thefe fhould be prepared of chamomile, hyffop, juniper-berries, and the carminative feeds, a little quantity of fal gem, crude fal ammoniac, or Epfom falt, in veal broth. After thefe, laxative medicines are to be given, with balfamic and carminative ingredients; and then the powders of zedoary, orange-peel, tartarum vitriolatum, are to be given; and, when neceffary, the pillulæ de ftyrace at proper intervals. In the mean time much fervice may alfo be done by external applications; fuch as the oils of mint, rue, nutmeg, and the like, with balfam of Peru; and the rubbing the belly with Hungary-water is often of immediate relief: By thefe means the flighter inflations of the ftomach and inteftines are ufually cured with eafe, and often beginning *Tympanies* yield to a continuance of them. *Hoffman.* Opera. T. 4.

TYPHIUM, in botany, a name ufed by fome authors for colts-foot. *Ger.* Emac. Ind. 2.

TYPHLE, or Typhline, a name by which fome authors have called the fifh, more ufually known by the name of the *acus*. *Willughby*'s Hift. Pifc. p. 158. See the article Acus.

TYPHLINUS, in zoology, the name by which the Greeks, and from them fome others, have called the *cæcilia*, or flow-worm. See the article Cæcilia.

TYPHOS, the name of a difeafe defcribed by Hippocrates and the old writers, and by them diftinguifhed into five kinds.

The firft kind of *Typhos* is a legitimate and continual fever, impairing the perfon's ftrength, and accompanied with pains in the abdomen, and a preternatural heat and weaknefs of the eyes, and a failure of fpeech.

The fecond kind begins with a tertian or quartan fever, and is attended with a pain in the head, and a large difcharge of faliva, and fometimes worms. The feet, and other parts of the body, are afflicted with foft fwellings, the eyes are painful, and the voice tremulous and faint, from the fticking of the faliva in the throat. The belly and back are alfo often in pain.

The third kind is diftinguifhed by the intenfe pains it gives in the joints, and fometimes over the whole body, and often with a lamenefs.

The fourth is known by the violent tenfion and pain of the abdomen which attends it; this is ufually followed by a diarrhœa, and fometimes by a dropfy.

The fifth kind is diftinguifhed by an unnatural palenefs all over the body, and a fort of tranfparence, as if the whole fkin were only a bladder, containing a watery juice, though not inflated; the eyes are hollow in this cafe, and the patient is continually feeling about the bed-cloaths, as if picking out threads. There is always an uneafinefs after eating, and frequent nocturnal pollutions.

The word *Typhos* is alfo ufed in a more general fenfe for *Typos*, to import the remiffions and exacerbations of difeafes.

TYPIC *Fevers*, an appellation given by medical writers to thofe fevers which are regular in their attacks, and in their general period: They are thus called by way of diftinction from the erratic, which obferve no regular type, or determinate appearance.

TYRANNUS, in zoology, a name given by fome to the lanius, or butcher bird, a fpecies of hawk, not larger than a thrufh, but a very fierce and fatal enemy to the fmall birds. *Ray*'s Ornithol. p. 52. See the article Lanius.

TYRBE, Τύρβη, in antiquity, a feftival celebrated by the Achæans, in honour of Bacchus. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 434.

TYRIUM *Marmor*, a name given by the antients to a fpecies of marble of a beautiful white, fometimes free from veins, and fometimes variegated with dufky blackifh grey ones. When pure, it was little inferior to the Parian, and often was ufed inftead of it by the ftatuaries.

TYROSIS, a name given by the antients to a diforder in the ftomach, occafioned by milk curdling in it, from the too great acidity of the humours.

TYRUS, a word ufed by fome of the barbarous writers for a ferpent or viper.

TZANATL, in zoology, the name of an American bird defcribed by Nieremberg, which, he fays, has all over very long and beautiful feathers, of a fine green, and of the fhining glofs of the feathers of the peacock. The upper fide of the wings is black, but their under part is of a very fine and fhaded green. It has a very beautiful creft on its head; its throat and breaft are of a fine fcarlet. The wing feathers are very long, and very beautifully variegated with feveral colours. The Indians efteem the feathers of this bird more valuable than gold; they drefs up the images of their gods with them. *Ray*'s Ornithol. p. 303.

TZANGÆ, among the antients, a kind of Parthian garments, according to fome; but others will have them to have been fhoes fet with precious ftones, formed into the figure of eagles, and defigned for the emperor's ufe. *Pitifc.* in voc.

TZANPAU, in zoology, the name of an American bird, defcribed by Nieremberg, and kept by the Spaniards in cages for its melody. It is famous for the modulations of its voice, and is by many efteemed the female of the polyglotta avis, or cencontlatolli of the Indians.

It is of the fize of our ftarling. Its breaft and belly are mottled with white, grey, and black, and its back with white, black, and a dufky brown. *Ray*'s Ornithol. p. 305. See the article Polyglotta *Avis*.

TZICATLINA, in zoology, a fpecies of ferpent, faid to be found in America, and reckoned among the moft beautiful of that kind of animals. It is nine inches long, about the thicknefs of a man's little finger, and variegated with alternate fwaths of white and red, croffing its body. It is likewife one of the harmlefs kinds of ferpents.

The name fignifies the *ferpent of ants*, becaufe it lives always in their nefts, and comes out along with them. *Hofman.* Lex. in voc.

TZINITZIAN, in zoology, the name of a very beautiful American bird, defcribed by Nieremberg, of the fize of a fmall pigeon, and ornamented with varioufly-coloured feathers. The beak is fhort, crooked, and of a pale colour; the head and neck are like thofe of the pigeon; the breaft and part of the belly are red; but that part which is next the tail is of a fine elegant blue, and a bright white, beautifully intermixed with one another; the tail is green on the upper part, and black underneath; the wings are variegated with white and black; the feet and legs are grey; and the fhoulders of a very beautiful green. It is moft frequent near the South-fea, and feeds on vegetables. It is kept in cages for its beauty, but never fings. The Indians make feveral beautiful works of its feathers. *Ray*'s Ornithol. p. 303.

TZTACTZON, in zoology, an American name under which Nieremberg has defcribed a fpecies of duck, remarkable for the variable and beautiful colours of its head, which are purple, blue, white, and green, and fhine like fattin. Its body is variegated with black, grey and white. Its legs are red, and is eaten as the other water-fowl. It is common in the lakes of Mexico; and has feet much more adapted to fwimming than to walking. *Ray*'s Ornithol. p. 299.

V

V in music, is often ufed to fhew that a piece is defigned for the violin; and VV, for two violins, or more.

V. S. is an abbreviation for *Volti Subito*. See the article VOLTI *Subito*.

VACCA, in zoology, the female of the ox-kind. See the articles Bos and Ox.

VACCARY, *Vaccaria*, in our old writers, a houfe or place to keep cows in; a dairy-houfe, or cow-pafture. *Flet*. lib. 2. *Blount*, *Cowel*.

VACCINIUM, in botany, a name by which fome authors have called the great bilberry, or *vitis idæa magna* of other writers. *Dale*, Pharm. p. 294.

VACUNALIA, among the Romans, a feftival kept in honour of the goddefs Lacuna.

It was celebrated in December by the country labourers, after the fruits were gathered in, and the lands tilled. *Pitifc*. Lex. Antiq. in voc.

VADIATION, *Vadiatio*, in the civil law. See the article VADARI, *Cycl*.

VA-EMBU, in the materia medica, a name given by fome authors to the *acorus Afiaticus*, or Afiatic fweet flag. Hort. Malab. vol. 11. p. 99.

VAGINA (*Cycl*.)—VAGINÆ *Femoris Tenfor*, in anatomy, a name given by Albinus to a mufcle of the thigh, called by others the *membranofus*, and the *mufculus fafciæ latæ*; and by fome *mufculus aponeuroticus*. See the article MEMBRANOSUS.

VAGINANS *Folium*, among botanifts. See the article LEAF.

VAGUE *Acid*, a term much ufed by the modern chemifts, and fignifying a certain volatile fluid falt or acid, fuppofed to be found every where in mines, and in combination with different other fubftances, to form many of the ordinary compound foffils.

This mixing with foffile oil, petroleum, oleum terræ, or the like, probably conftitutes the various forts of native foffile tranfparent fulphurs; uniting with femi-metals, it forms cinnabar, antimony, and other foffils, both folid and fluid; uniting with metals, it forms divers kinds of vitriols; with calcarious earths, different alums; and laftly, with pyrites, which is the matrix of vitriol, calcined in a wood-fire, it produces common fulphur.

It may probably be held much of the fame nature with that acid, which burning fulphur diffufes from its blue flame, fo fuffocating and fatal to all animals. Certainly the analyfis feems to intimate as much. And hence this may probably be looked upon as a male falt, ferving to impregnate the female falts and earths. *Boerhaave*, Chem. 112.

There feems to be a certain *vague* falt or acid diffufed in all parts of the earth, which, when alone, is volatile; but when it has a body, or proper fubject to adhere to, it becomes fixed. The idea of this falt we are at a lofs how to convey, otherwife than by its effects; it feems to come neareft the nature of fpiritus fulphuris per campanam, and is difcovered in all fulphur, in all vitriol, in all alum, in all nitre, in all foffile coal, and many other fubftances; and is, perhaps, that pernicious fume or damp found in mines, and the fmoke which flies from bituminous turf, and other the like bodies.

It is looked upon as an indeterminate principle, diftributed through every part of the globe, both infide, and out. It is this acid that diffolves iron and copper near fome hot baths. It is this that, meeting with foffile oil, becomes coagulated, and is converted into fulphur; that being received into the earthy part of the lapis calcarius, converts it into alum; and infinuating itfelf into the fubftance of iron, produces green vitriol; into that of copper blue vitriol.

This doctrine of a *vague* acid may feem a little hypothetical, till the actual feparate exiftence of fuch an acid can be fhewn; of which we do not know any clear inftances. The argument for it ftands thus: We find feveral mineral bodies that afford acids upon their analyfis; or appear to contain acids; and therefore nature makes ufe of thefe acids in the compofition of fuch mineral bodies: But to render this argument conclufive, the acids fhould be fhewn to exift in the earth, and inftances be produced of nature's working in this manner, with the feveral fteps of the procefs. Inftead of this direct proof, we only find a prejudged theory in authors, fupported indeed by probable reafonings, and a plaufible folution of phænomena: But all this may poffibly be no more than a bare accommodation to the mind. *Shaw*, Chem. 112.

VAI-*Hio*, in the materia medica, a name ufed by fome authors for a kind of lignum aloes, which is brought from China, and is very black, and fcented. *Dale*, Pharm. p. 448.

VAISSEAUX *Enfilez*, a term ufed by the French writers in chemiftry, for thofe veffels ufed in diftilling in an open fire, or in fand, which do not confift in the common way of a retort, joined immediately to a receiver, but have a receiver with a double opening, and a neck at each end, placed between the retort and the ordinary receiver. The neck of the retort is let into one of the necks of this middle veffel, and its other neck is thruft into that of the receiver; by this means the receiver, into which the liquor is to fall, ftands at a greater diftance than it otherwife would from the fire, and the vapours are more eafily condenfed in it by its coolnefs, while they have alfo a double or treble fpace to expand in, and by that means are not fo likely to burft the veffels.

VALDIA, in botany, a name given by Plumier to a genus of plants, fince called by Linnæus, *ovieda*. *Plumier*, Gen. 24. See the article OVIEDA.

VALE *of a Pump*, at fea, a term for the trough by which the water runs from the pump along the fhip-fides, to the fcupperholes.

VALERIAN, *Valeriana*, (*Cycl*.) in the Linnæan fyftem of botany, makes a diftinct genus of plants, taking in the *valerianella* of Tournefort, and the *valerianoides* of Vaillant.

The characters of this genus are, that the cup fcarce deferves the name of one, and is only a fort of rim or foliaceous edge, furrounding the germen. The flower confifts of a fingle petal, in form of a tube, prominent in its inferior part, and containing a honey juice, divided into five fegments at the edge, all which are obtufe. The ftamina are three, or fewer, pointed, erect filaments, and of the fame length with the flower. The antheræ are roundifh. The piftillum has its germen below the receptacle. The ftyle is thread-like, and of the fame length with the ftamina; and the ftigma is fomewhat thick. The fruit is a capfule, that fplits and falls off. The feeds are fingle and oblong. Thefe are the characters of the genus; but there is great variation among the different fpecies. *Linnæi* Gen. Plant. p. 8.

The characters of this genus, according to Tournefort, are thefe: The flower confifts of one leaf, and is fhaped like a funnel, and divided into feveral fegments at the edge. This ftands upon a cup, which finally becomes an oblong feed, of a flattifh form, and winged with down.

The fpecies of *Valerian*, enumerated by Mr. Tournefort, are thefe: 1. The great Pyrenean *Valerian*, with the leaves of cacalia. 2. The fcentlefs Alpine *Valerian*, with undivided leaves, and a creeping root. 3. The middle marfh *Valerian*, with flightly divided leaves. 4. The firft Alpine *Valerian* of Cafpar Bauhine. 5. The other Alpine *Valerian*, of the fame author. 6. The figwort-leaved Alpine *Valerian*. 7. The roundifh-leaved mountain *Valerian*. 8. The Alpine *Valerian*, refembling the celtic Spikenard. 9. The cretic *Valerian*, with the dropwort-root. 10. The celtic *Valerian*, commonly called celtic fpikenard. 11. The common broad-leaved red *Valerian*. 12. The fmall narrow-leaved red fea-*Valerian*. 13. The common narrow-leaved red *Valerian*. 14. The great broad-leaved fea *Valerian*. 15. The fmall narrow-leaved, white-flowered fea *Valerian*. 16. The garden *Valerian*. 17. The great wild *Valerian*. 18. The great wild *Valerian*, with fhining leaves. 19. The great marfh *Valerian*. 20. The fmaller marfh *Valerian*. 21. The little marfh *Valerian*, with a fmall flower. 22. The little Alpine *Valerian*. 23. The annual *Valerian*, with leaves like thofe of the calcitrapa. 24. The broad-leaved annual jagged Portugal *Valerian*. *Tourn*. Inft. p. 131.

The *Valerians* may be known, when not in flower, by their roots being fcented, and their leaves always ftanding two at a ftalk.

The great garden *Valerian* is an alexipharmic, fudorific, and diuretic. The root is the only part of it ufed in medicine; this is to be taken up in September, and carefully dried. It is then given in powder in afthmas, pleurifies, coughs, obftructions of the liver and fpleen, and in the plague, and all malignant and petechial fevers. It is alfo recommended by fome as a vulnerary, and by others as one of the greateft medicines in the world for weakneffes of fight.

The wild *Valerian* root is much more famous than this, but in a different intention. It is of a ftrong difagreeable fmell, and is given in nervous cafes with very great fuccefs. There are not wanting inftances of perfons cured of confirmed epilepfies by it. In all convulfions it is a very fuccefsful medicine.

VALERIANELLA, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf,

leaf, ſhaped like a funnel, and divided into ſeveral ſegments at the edge. This ſtands upon a cup, which afterwards becomes a fruit, always containing one ſeed only, but yet is of very various figures; one ſort is like a ſpear-point in ſhape, being compoſed of two flat pieces, containing a ſeed in one or the other of them; another is of an oval ſhape, umbilicated, and terminated by three points; others have beautifully regular hollows cut in each for a ſingle ſeed; others are longer, fungoſe, and lunated, containing a cylindric ſeed; and finally, others terminate in three hooks, and contain a ſomewhat crooked ſeed.

The ſpecies of *Valerianella*, enumerated by Mr. Tournefort, are theſe: 1. The low early field *Valerianella*, with flatted ſeeds. 2. The low early field *Valerianella*, with ſerrated leaves. 3. The taller late-flowering field *Valerianella*, with more turgid ſeeds. 4. The *Valerianella* with naked round umbilicated ſeeds. 5. The *Valerianella* with naked umbilicated ſeeds. 6. The *Valerianella*, with large hairy umbilicated ſeeds. 7. The *Valerianella*, with ſmall hairy umbilicated ſeeds. 8. The Indian *Valerianella*, with a galeated, purple, or white flower. 9. The ſtarry ſeeded *Valerianella*. 10. The great Portugal *Valerianella*, with ſeeds like thoſe of ſcabious.

The ſeveral ſpecies of this genus may be known, when not in flower or ſeed, by their ſtalks being always divided regularly into two, and their leaves being ſmooth, veiny, and and placed two at each joint. *Tourn.* Inſt. p. 132.

VALET, (*Cycl.*) in the manege, a ſtick armed at one end with a blunted point of iron, to prick and aid a leaping horſe.

Formerly a *Valet* was called *Aiguillon*, *i. e.* goad, and ſome of them had ſpur-rowels upon them, only the points beaten down: And when a horſe was firſt begun round a pillar, without a rider, they uſed to prick his flanks with the *Valet*, to make him know the ſpur, and obey it, without reſiſting. At preſent the *Valet* is not uſed for that purpoſe, and the name of *goad* is ſuppreſſed, as being only proper for oxen.

VALIGA, a name given by ſome medical writers to an infuſion or tincture of jalap in ſpirit of wine, or ſpirit of citron, with the addition of a little ſaffron.

VALVULÆ *Conniventes*. Mr. du Vernoi is of opinion, that the *Valvulæ Conniventes* of the inteſtines are formed by the arched veſſels and fat in the internal cellular coat, and covered by the villous or nervous coat. See Comment. Acad. Petrop. Tom. 4. p. 192.

VAN (*Cycl.*)—VAN *of a Fleet*. See the article SQUADRON.

VANDOSIA, in zoology, a name by which ſome authors have called the *leuciſcus*, the common dace, or dare. *Willughby*'s Hiſt. Piſc. See the article LEUCISCUS.

VANELLUS, in zoology, a name given by many to the lapwing, more commonly known by the name *capella*. See the article CAPELLA.

VANILLA (*Cycl.*)—This fruit is principally brought to us by the Spaniards, who traffic with the Americans for it. It grows in the warmer parts of America, and that uſually in places where there is water near. The natives diſtinguiſh it into three kinds, which the Spaniards call the *pompona*, the *ley*, and the *ſimarona*.

The pods of the *pompona* kind are thick and ſhort; thoſe of the kind called *ley*, are longer and ſlenderer; and thoſe of the *ſimarona*, which is alſo called *baſtard Vanilla*, are the ſmalleſt of all the kinds.

The *ley* kind is the only good *Vanilla*. It ought to be of a good reddiſh brown, neither too black nor too red, and neither too dry nor too moiſt; when perfect they always appear full, though dry; and a parcel of fifty in number ought to weigh above five ounces.

There is a kind which is larger, fifty pods of which uſually weigh eight ounces; this is called the *ſobre buena*, and is eſteemed of all others the moſt excellent.

The ſmell of the *Vanillas* ought to be penetrating and agreeable. And when the pods are freſh, and in good condition, they are found, when opened, to be full of a blackiſh oily balſamic liquor, in which there ſwim a great number of very ſmall black ſeeds. The ſmell, when the pod is freſh opened, is very lively, and in ſome degree intoxicating.

The *pompona Vanilla* has a ſtronger, but leſs agreeable ſmell than the former, and when taken, gives men violent headachs, and women diſorders of the womb. The liquid ſubſtance in the *pompona* is thinner than in the *ley*, and the ſeeds much larger, being nearly of the ſize of thoſe of muſtard.

The *ſimarona*, or *baſtard Vanilla*, has very little liquor, and has few ſeeds in the pod, and has ſcarce any ſmell.

The *pompona* and *ſimarona* are no ſaleable commodities, nor ever brought to market, except cunningly by the Indians, who mix them among the pods of the *ley*, or true kind. It is not yet certainly known, however, whether theſe three kinds are the produce of different ſpecies of plants, or whether they differ only as to age, or the ſoil where the plant grows.

They never put *Vanilla* into chocolate in any part of New Spain. There has been ſent over into France *Vanilla* from Caracca and Maracaybo. The pods of this are ſhorter than thoſe of the true *Vanilla*, and thicker than the *pompona* kind. It is, however, plainly a ſpecies of *Vanilla*, and is of a very good ſmell and taſte. There is alſo mention made by ſome of a *Vanilla* of Peru, the dried pods of which are two fingers wide, and above a foot in length; but of a much inferior ſcent to the *Vanilla*, and not retaining any long time even what it has.

The leaves of the *Vanilla* plant are about a foot long, and three fingers breadth wide. They are obtuſe at the end, and of a very dark duſky green. The flowers are ſingle, and of a whitiſh colour, variegated with red and yellow. The pods appear as ſoon as theſe fall, and are green at firſt, but grow of a yellowiſh colour as they ripen. It is at this time that they gather them. The whole ſhrub is a climber, of the nature of the vine, and muſt be thtee or four years old before it produces any fruit.

The time of gathering the pods for ſale is from September to December. They require no other management than to be gathered in a dry ſeaſon, and laid twenty days, to dry away the ſuperfluous humidity, and, at times, preſſing the pods gently with the hands.

The plant climbs up the talleſt trees, and its main ſtock, in time, becomes woody and hard as that of the vine; the root ſends up many off-ſets, which are planted by the natives, near the foot of a tree, and thrive very eaſily; and it is thus that the ſhrubs are propagated; and the time for doing this is in winter, or toward the beginning of ſpring.

It is remarkable that the young ſhoot is not to be planted into the ground as with us, but on the bark of the tree; this is, however, no ſingular caſe in the hot countries, for nature ſhews the way; the branches of trees, broken off by winds, often being blown againſt other ſpecies, and yet always taking hold on them, and growing; this is owing to the great abundance of the ſap in trees in theſe climates. Memoirs Acad. Scien. Par. 1722.

Vanillas are accounted cordial, carminative, ſtomachic, and reſtorative; they are alſo ſaid to be diuretic, and to promote the menſes.

VANNING-*Shovel*, among miners, an inſtrument uſed for waſhing the ores of any metal, after being reduced to powder, thereby to diſcover the richneſs and other qualities of the ore. See the article SHOAD.

VAPOUR (*Cycl.*)—*Fiery* VAPOURS, *Halitus Ignei*, a term uſed by ſome to expreſs thoſe exhalations from the earth, which either take fire of themſelves on the burſting forth into the air, or are readily inflammable on the bringing a candle to them.

Many of the ſuppoſed burning lakes are owing to theſe fumes burſting up through the water, and not to any quality of the water itſelf. Our famous burning well at Wigan in Lancaſhire is of this kind. The common people affirm, that the water of this ſpring burns like oil; but there is nothing of truth in this. There burſts up a *Vapour* through the earth in this place, which keeps the water bubbling, as if boiling over the fire, though it is not warm; and the ſtream of this breath may be felt iſſuing up in theſe places like a ſtrong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with conſiderable violence for ſome time.

There are coal-pits in the neighbourhood, and the air is certainly of the ſame kind with that inflammable *Vapour*, often met with in thoſe places, and which may alſo be prepared from iron diſſolved in a proper menſtruum. The water itſelf, taken from the place, does not burn; and if the bottom be made dry, the vapour which aſcends from it will burn as ſtrongly as if the water were there. The flame is not diſcoloured like that of ſulphureous bodies, nor has it any bad ſcent; and the fumes, as they are felt burſting out of the earth, by the hand held over the place, are not hot. Phil. Tranſ. N° 20.

VAPPA, a word uſed by the antients to expreſs dead wine, or wine deprived of all its ſpirituous part.

The word is alſo metaphorically uſed to a peculiar ſtate of the blood, when it is in a low, diſpirited condition, as is the caſe even in healthy perſons, when worn out with exceſſive labour, and in cachectic and ſcorbutic perſons.

VARA, in commerce, a long meaſure uſed in Spain and Portugal. It is of various lengths in different places. That of Seville is $33\frac{127}{1000}$; that of Madrid, $39\frac{166}{1000}$; that of Portugal, $44\frac{31}{1000}$ inches Engliſh meaſure. Treat. Pract. Geom. p. 8.

VARIA, in zoology, a name by which ſome authors have called the leopard, or *pardalis*, from the beautiful variegations it is marked with. See the article PARDALIS.

VARIATION (*Cycl.*)—VARIATION *of Curvature*, in geometry, is uſed for that inequability, or change, which happens in the curvature of all curves, except the circle. And this *Variation* or inequability conſtitutes the quality of the curvature of any line. *Newton*, Meth. of Flux. and Inf. Series. p. 75.

Sir Iſaac Newton [a] makes the index of the inequability, or *Variation* of curvature, to be the ratio of the fluxion of the radius of curvature, to the fluxion of the curve; and Mr. Maclaurin, to avoid the perplexity that different notions, connected with the ſame terms, occaſion to learners, has adopted the ſame definition; but he ſuggeſts [b], that this ratio gives rather the *Variation* of the ray of curvature, and that it might have been proper to have meaſured the *Variation* of curvature, rather by the ratio of the fluxion of the curvature itſelf,

itſelf to the fluxion of the curve; ſo that the curvature being inverſely as the radius of curvature, and conſequently, its fluxion as the fluxion of the radius itſelf directly, and the ſquare of the radius inverſely, its *variation* would have been directly as the meaſure of it, according to Sir Iſaac Newton's definition, and inverſely as the ſquare of the radius of curvature. According to this notion, it would have been meaſured by the angle of contact contained by the curve and circle of curvature, in the ſame manner as the curvature itſelf is meaſured by the angle of contact contained by the curve and tangent. The reaſon of this remark may appear from this example [c]. The *variation* of curvature, according to Sir Iſaac Newton's explication, is uniform in the logarithmic ſpiral, the fluxion of the radius of curvature in this figure being always in the ſame ratio to the fluxion of the curve; and yet, while the ſpiral is produced, though its curvature decreaſes, it never vaniſhes, which muſt appear a ſtrange paradox to thoſe who do not attend to the import of Sir Iſaac's definition. — [[a] Meth. of Flux. and inf. Series, p. 76. [b] Fluxions Art. 386. [c] Phil. Tranſ. N°. 468. ſect. 6. p. 342.—]

The *variation* of curvature at any point of a conic ſection, is always as the tangent of the angle contained by the diameter that paſſes through the point of contact, and the perpendicular to the curve at the ſame point, or to the angle formed by the diameter of the ſection, and of the circle of curvature. Hence the *variation* of curvature vaniſhes at the extremities of either axis, and is greateſt when the acute angle, contained by the diameter, paſſing through the point of contact and the tangent, is leaſt.

When the conic ſection is a parabola, the *variation* is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve.

VARICULA, a diminutive of the word *varix*, a term applied by ſome authors to the intumeſcence of the veins of the tunica adnata in the eye, ariſing from thick blood.

VARIETIES, in natural hiſtory, a word uſed to expreſs an accidental change in ſome body which is not eſſential to it, and therefore does not conſtitute a different ſpecies.

The naturaliſts of former ages have run into great errors, in miſtaking the accidental *varieties* of plants, animals, and minerals for diſtinct ſpecies. Many of them have called a plant a new ſpecies, becauſe its flower, which ſhould have been blue or red, is white on account of the poorneſs of the ſoil, or ſome other ſuch reaſon. Mr. *Ray* has eſtabliſhed a very good teſt for *varieties* in botany; he allows every thing to be a diſtinct plant which will propagate itſelf in its own form by its ſeeds; but ſuch, as when ſown, loſe their difference, and run back to the old ſtandard, he accounts *varieties*, however great their diſtinctions may appear. In the hiſtory of fiſhes as much confuſion has been introduced by miſtaking *varieties* for diſtinct ſpecies as in botany. Artedi is the only author who has rationally attempted to bring this part of natural hiſtory into order in this reſpect, and to ſettle regularly the rules by which to diſtinguiſh real and eſſential, from accidental differences.

The principal grounds of the error of ſuppoſing *varieties* diſtinct ſpecies of fiſh, have been theſe: The variable and inconſtant colour of fiſhes has been miſtaken for a ſpecific difference; in this manner Rondeletius has deſcribed many *varieties* of the turdi, labri, and other fiſhes, under the names of diſtinct genera.

Others have paid the ſame too great regard to the more conſtant *varieties* of colour, which are found only to differ in degree, in the ſeveral individuals of the ſame ſpecies, and their differences to be only in the degrees of the ſame colour, which is much more intenſe in ſome, and more remiſs in others. Theſe differences can only make *varieties* of the ſame fiſh, the ſpecies remaining always the ſame. Of the ſame kind are the miſtakes of thoſe who eſteem ſize or magnitude a ſpecific character: and thus, out of the *varieties* of the ſame fiſh, occaſioned by ſcarcity or plenty of food, or other ſuch occaſions, make larger or ſmaller ſpecies. The place where fiſh are caught, is alſo another occaſion of making new ſpecies, with theſe ſort of authors; thus though the *perca fluviatilis* of Bellonius, and the *perca marina* of other authors be the ſame fiſh, yet they are pretended to be different ſpecies. The time of ſpawning is alſo with ſome made a diſtinction of ſpecies; and thus we find the common pike divided into three ſpecies, according to its ſpawning, in ſpring, ſummer, and autumn, which it does according to the heat or coldneſs of the climate. See the article SPECIFIC *Names*.

All theſe differences are falſe and frivolous, and the utmoſt they can do, is to make what are properly called *varieties*, though few of them are ſufficient even for that. A ſalmon caught at ſea, is not different from one of the ſame brood caught in a river: and if the *perca marina*, falſly ſo called, be a little different from the *perca fluviatilis*, yet if its ſpawn will produce regular *percæ fluviatiles*, its difference can only amount to a *variety*, not a diſtinct ſpecies.

The trifling nature of diſtinction by colour, is ſeen by the variety we daily ſee in the colours of ſome of our moſt common fiſh; as the tench, the eel, the ſalmon, and ſome others, which vary more or leſs, from every change of the water; all the other diſtinctions, of ſize and place, are as frivolous; and the giant and the dwarf, the black and the white man, the Aſiatic and the European, may as well be called diſtinct ſpecies of men, as theſe of fiſhes.

Finally, the time of ſpawning is no eſſential difference; for we daily ſee the change of climate make changes of that kind in all creatures; and even in the ſame climate, and under the ſame circumſtances, the ſame ſpecies of birds will afford ſome individuals much earlier or later in laying their egg ſthan others. *Artedi* Ichthyol.

VARIUS, in zoology, a name uſed by moſt authors for a ſmall freſh-water fiſh, common in brooks and running waters, and well known in England, by the name of the *minow*, or *menow*; and called *Phoxinus lævis* by ſome other writers.

It is diſtinguiſhed from other fiſh of its ſize, by being of a duſky browniſh olive colour on the back, by its having a yellow line running on each ſide, from the gills to the tail, below which the belly and ſides are of a very varying colour; in ſome white, in others of a fine bright red, and in others, there is a line of a fine blue running on each ſide; and in others, the ſides are variegated with yellow, brown, and red lines. Its ſcales are ſo extremely ſmall, that it has been generally ſuppoſed to have none. Its mouth is very large. It is a very well taſted fiſh, and if but a little larger, would be very much valued. *Ray*'s Ichthyogr. p. 268.

VARIUS *Mus*, in the old authors of zoography, a name uſed for the ſame creature they otherwiſe called *mus ponticus*; which ſeems to have been no other than our ſquirrel. See the article SCIURUS.

VARNISH *(Cycl.) Amber* VARNISH. *Amber Varniſh* is prepared in the following manner: Put four ounces of amber into a crucible, and melt it with a ſmall degree of heat, and pour it out upon an iron plate, when cold, reduce it to powder, and add to it two ounces of drying oil, that is, linſeed oil thickened by boiling it up with litharge, and one pint of oil of turpentine, and diſſolve the whole together into a liquid *Varniſh*. *Shaw*'s Lectures, p. 424.

This has been long a great ſecret in the hands of the traders in theſe things; but deſerves to be made public, as a leading experiment towards the perfecting the arts of *varniſhing* and japanning.

China-VARNISH. The *China Varniſhes* have been always famous; the manner of making which is ſaid to be as follows: Take crude *Varniſh* ſixty ounces, common water the ſame quantity, mix them well together till the water diſappears; afterwards put this into a wooden veſſel five or ſix palms long, and two or three broad; mix them together with a wooden ſpatula, for a whole day in the ſummer's ſun, for two days if in winter, and afterwards keep it in an earthen veſſel, covered with a bladder. The water will not unmix itſelf again: this is called the ſun *Varniſh*. See VARNIH *for Porcelain*, *infra*.

The oil of wood, called by the Portugueſe *azeile de Pao*, is made in the following manner: Take twenty ounces of that oil, which they call oil of wood, and ten drams of the oil of the fruit; boil theſe a little together, and the oil will look yellow; then let it cool, and add to it five drams of quick lime powdered. To make the firſt grounds called *camiſeca*, take ſwine's blood and quick lime powdered, of each an equal quantity; ſpread this mixture upon the wood, and when it is dry, ſmooth it with pumice-ſtones.

To make the black *Varniſh*, take of the *Varniſh* prepared in the ſun ſixty ounces, ſtone black alum (ſuppoſed to be a ſort of copperas) diſſolved in a little water, three drams, and ſeventy drams of lamp-oil, called by the Portugueſe *azeile de Candea*. Theſe things are all to be mixed together in a wooden veſſel, putting the lamp oil in at twice, and ſtirring the whole together with a wooden ſpatula.

The pitch-coloured *Varniſh* is made in the following manner: take oil of wood, crude, forty drams; called *da Pao*, of the lamp-oil, called *da Candea* crude, forty drams; mix them together in the ſun in a wooden veſſel, in the ſame manner as the common *Varniſh* and water are ordered to be mixed in the firſt proceſs.

To make the red *Varniſh*, take ten drams of cinnabar, twenty drams of prepared *Varniſh*, and a little lamp-oil; mix, them all together.

To make the yellow *Varniſh*, take of the yellow colour ten drams, prepared *Varniſh* thirty drams, a little lamp-oil; mix all together: and

To make a *Varniſh* of a muſk colour, take of the red *Varniſh* ten drams, and of the black *Varniſh* four drams; mix them well together. Philoſ. Tranſ. N°. 261. p. 524.

Theſe are the accounts ſent to the great duke of Tuſcany by the jeſuits in China: Dr. William Sherard communicated them to the royal ſociety; and to render the accounts uſeful to the world, he preſented with them the ſeveral ſubſtances mentioned; theſe are depoſited in the muſæum of the ſociety, and may ſerve as inſtructions to all who are curious in this art.

VARNISH *for Porcelain*. The Chineſe have of late years diſcovered a new kind of *Varniſh* for their ware: they call this *Tſekinyeou*, that is to ſay, the browniſh gold varniſh; it is of the colour of the brown images, or of what we call coffee colour. The novelty of this has made it much eſteemed: it is made in the manner of all their other varniſhes, by diſſolving

ing the finer part of an earthy fubftance in water. The fubftance which they make it of is a common yellow earth: this they diffolve in water, and letting the coarfe parts fettle, they pour off the yet thick liquor, and what afterwards fubfides from this, is the pure and fine part, which they keep in form of a foft pafte, or thick cream. They ufe this only to the thinneft and moft delicate porcelain ware.

The manner of ufing it is this: they mix a quantity of this fine fediment with fo much water as renders it thin and liquid, like the common *Varnifh*: this and the common kind are to be ufed together, fo that care muft be taken that they are nicely of the fame degree of thicknefs: this the workmen try by dipping a petunfe or brick of their earth into both, and feeing which comes out moft covered, that which lies on the thickeft, is to be diluted with more water, or the other to be heightened with more of the earth, to bring them to the fame ftandard. They are both judged to be fufficiently liquid when they enter the pores of the petunfe. They then mix fome of the oil of fern afhes and lime, (fee the article FERN-*Oil*) along with the brown *Varnifh*, and add as much of this mixture to the common *Varnifh* as they find upon trial will give fuch a colour as is required. The common proportion for the brown colour moft efteemed at prefent, is two pints of the brown *Varnifh* to eight pints of the common; and to four pints of this mixture they add one pint of the *Varnifh*, or oil of fern. It might puzzle a ftranger to their terms, to underftand what thefe people meant by oil; but it is a word with them in ufe for any thing liquid; and they call all their *Varnifhes* fo, though made of the powders of earths and ftones mixed with water. They apply this *Varnifh* to the veffels by dipping them into it, and fo compleatly covering them infide and out before they put them into the oven; and the baking gives a great brightnefs to the colour. This is the niceft part of the whole manufactury of the porcelain, and other wares of that kind. The *Varnifhes* ufed by the Chinefe are two; the one they call *oil of ftones*, the other, *oil of fern*; which fee. They mix thefe together, and with great caution and delicacy apply them to the veffels all over equally, with a fteady hand and a fine pencil. Obfervat. fur les Coutum. de l'Afie, p. 304.

When the porcelain is very thin and fine, they give it two beds of the *Varnifh*, the one over the other, when dry; thefe are to be very thin, and they anfwer to the fingle covering of *Varnifh* given to the common good China, that is thick and ftrong. They give thefe coats by dipping, and ufe the foot of the veffel to hold it by: after this, they hollow the foot, and paint the circle that we fee round it, or mark it with fome Chinefe character.

The *Varnifh* they lay on is fo thick, that it often hides the colours, till the baking afterwards brings them out again: this is the cafe with the fine deep blues; we fee none on the beft china; it is all hid under the coat of white, and the veffel appears plain, till it has paffed through the fire again; but then the colour appears deeper than when at firft laid on. Obferv. fur l'Afie.

VASTUS (*Cycl.*)—VASTUS *Externus*, a very large flefhy mufcle, almoft as long as the os femoris, broad at the extremities, and thick in the middle, and lying on the outfide of the thigh.

Its upper infertion being fomething tendinous, is in the pofterior or convex rough furface of the great trochanter. It is likewife fixed by a flefhy infertion along the outfide of the os femoris, for above two thirds of its length downward, in the correfponding part of the linea afpera, and in the neighbouring portion of the fafcia lata. From all this extent, the flefhy fibres running downward, and a little obliquely forward, towards the rectus anterior, terminate infenfibly in a kind of fhort aponeurofis, which is fixed in all the neareft edge of the tendon of the rectus, in the fide of the patella, in the edge of the ligament of that bone, and the neighbouring lateral part of the head of the tibia. The body of this mufcle is bigger than its extremities, and its loweft fibres run a little below the rectus. *Winflow's* Anatomy, p. 213.

VASTUS *internus*, a mufcle very like the *vaftus externus*, and fituated in the fame manner on the infide of the *os femoris*.

It is fixed above by a fhort flat tendon in the anterior rough furface of the great trochanter, and by flefhy fibres in that oblique line, which terminates the bafis of the collum of the os femoris anteriorly on the forefide of the infertions of the pfoas and iliacus, in the whole infide of the os femoris, and in the linea afpera on one fide of the infertions of the three tricipites, almoft down to the internal condyle. From all this extent, the fibres run downward, and a little obliquely forward, and the body of the mufcle increafes in bulk: it terminates below in an aponeurofis, which is fixed in the tendon of the rectus anterior, in the fide of the patella, and of its tendinous ligament, and in the fide of the head of the upper extremity of the tibia. *Winflow's* Anatomy, p. 214.

VATERIA, in botany, the name of a genus of plants; the characters of which are thefe: The perianthium is fmall, acute, and permanent, and is compofed of one leaf, divided into five fegments; the flower confifts of five oval expanded petals; the ftamina are numerous filaments, fhorter than the flower; the antheræ are fimple; the germen of the piftil is roundifh; the ftyle is fimple and fhort, and the ftigma is headed; the fruit is turbinated and trivalved; the feeds fingle and oval. *Linnæi* Gen. Plant. p. 235. Hort. Mal. vol. 4. p. 15.

VATICANÆ *Pillulæ*, the name of an old form of medicine, intended as a purge. The recipe is in the Old London Pharmacopœa; but the late ones have difcarded it.

VAULT (*Cycl.*)—VAULT, in the manege. To *vault* a horfefhoe, is to forge it hollow, for horfes that have high and round foles; to the end that the fhoe, thus hollow or *vaulted*, may not bear upon the fole that is higher than the hoof; but after all, this fort of fhoe fpoils the feet; for the fole being tenderer than the fhoe, affumes the form of the fhoe, and becomes every day rounder and rounder. In Mr. Solleyfel's Compleat Horfeman, may be feen the true method of fhoeing for high and round foles.

VAUNING, in mineralogy, a term ufed by our miners to exprefs a coarfe and expeditious way of wafhing ores, for the examination of their nature and richnefs.

This inftrument called the *Vaun*, is a long and moderately deep wooden fhovel; into this they put the earthy or ftony matter, which they fufpect to contain the metal, in powder: they then add water many times, and fhaking and ftirring it thoroughly about, they throw out the water, and add frefh, till at laft the matter is feparated; the earthy part is wafhed away, and the ftony and mineral matter only remain, the one at the hinder part, the other at the point of the fhovel. This laft is collected feparate; and on being examined either by the eye or teft, they are able to judge very nearly of the general profit of the mine.

This method is often ufed with the ftones and earths found in the fhoads, or trains of mines. Phil. Tranf. N°. 69.

VAZABU, in the materia medica, a name by which fome authors have called the *Acorus Afiaticus*, or Afiatic fweet flag. *Herm.* Muf. Zeyl. p. 56.

UBIRRE, in zoology, a name given by fome to the anguilla marina, or fmall fea eel, a long fifh of the eel kind, living among rocks about the fea fhores, and growing to be very fat and well tafted. *De Laet's* Ind. occident. See the article EEL.

UDNON, in botany, the name by which Theophraftus and Diofcorides have called the truffle commonly ufed at table in their time.

Diofcorides tells us, that it was a root dug up at fmall depths under ground, and had neither ftalks, nor flowers, nor leaves; and that it was of a reddifh colour, and fmooth furface. By this, which is alfo the account of Theophraftus and Athenæus, we find, that the *Udnon* was indeed the truffle; but we alfo find that they were not acquainted with the better kind of truffle, which we cultivate at prefent.

This fmooth reddifh-coated truffle is common in Italy at this time, and is efteemed of no value, and called the wild truffle: the fort that is eaten there, and in all other parts of Europe, is the blackifh and rough-coated kind. In Africa they have a yet finer kind than ours; it has a white coat, and is of the moft delicious flavour. The Greeks were alfo acquainted with this, and denominated it Cyrenean, as they did almoft all the things they had from Africa: they alfo gave it the name *mify*; but this word being alfo the name of a vitriolic mineral, allied to the *fory* and the *melanteria*, fome confufion has been thereby introduced. Many having thought, that the Cyrenean mify was only a finer kind of the mineral of that name. See the article MISY.

UDO, in the materia medica, a name given by the *Portuguefe* to the lignum aloes. See the article LIGNUM *Aloes*.

It feems only a corruption of the monofyllable *Ud*, by which the Arabian phyficians have called that drug; and even this *Ud* poffibly was only a contraction of the orthography of the word *Heud*; which feems to have been the original name of this drug among the Arabs. See the article HEUD.

VEERING, in hufbandry, a term borrowed of the failors, and ufed for the turning two furrows toward each other, as they muft do to begin a ridge; they therefore call the top of a ridge a *Veering*; and they call the two furrows that are turned from each other at the bottom between two ridges, a *henting*, that is, an ending, becaufe it makes an end of plowing ridges.

VEGETABLE (*Cycl.*)— *Vegetables*, according to the analyfes made of them by chemiftry, are diftinguifhable into two grand tribes, the acid and the alkaline; the firft affording a volatile acid, and the fecond a volatile alkali, upon a dry diftillation: thus guaiacum, cedar, box, cinnamon, cloves, forrel, mint, balm, &c. afford an acid; but garlick, leeks, onions, horfe-radifh, fcurvy-grafs, muftard, &c. afford an alkali, which, when rectified, is hardly diftinguifhable from that of animal fubftances, fo as nearly to refemble the fpirit and falt of hartfhorn.

For the analogy between the animal and *vegetable* world. See the article ANIMAL.

Mufcles of VEGETABLES, fee the article MUSCLE.

VEGETABLE *Salt*. In the Philofophical Tranfactions we have fome very curious proceffes and obfervations by Redi, on the fubject of the falts of *Vegetables*. Burn any wood, herb, fruit, or flower to afhes; make a lye with thefe afhes with common water, not heated; filtre this through paper till it is clear as rock-water; then evaporate this lye to a proper degree in a balneum mariæ, in a glafs veffel. This degree of evaporation

tion muſt be carefully obſerved, according as the congelation of the ſalt is intended to be haſtened or retarded. In the common way of evaporating lixiviums of this kind in earthen veſſels over a naked fire, a great quantity of the ſalt is always loſt; part of this is carried off with the vapours raiſed too haſtily in this manner, and part penetrates the ſides and bottom of the veſſel, though it be ever ſo well glazed. The quantity of water neceſſary, is, in moſt caſes, about five pints to two pound weight of the aſhes. After all the ſalt that can be got is extracted by this operation, the aſhes being calcined again in a kiln, will afford more ſalt of the ſame kind, but in a much ſmaller quantity.

The ſalts of *Vegetables* made in this manner, are ſubject to run into water in damp weather, unleſs very carefully kept; but in this, art may be employed, and the running in a great meaſure prevented. Thus, if ſome ſulphur be added to the aſhes, when their burning is almoſt over, and conſumed by burning among them, very little difference will be made in the nature of the ſalts, but they will be more white and cryſtalline, and will keep much better. The proportion of ſulphur is to be in ſome meaſure regulated by the quantity of ſalt the aſhes are known to yield; but on a medium, five ounces of ſulphur is enough to add to a hundred pounds of aſhes. When the *vegetable* ſalts are thus made, they have each their peculiar figure, and this they retain, though diſſolved and cryſtalized again ever ſo often. If two or three of theſe ſalts, thus carefully made, and which have each their determinate figure, be diſſolved together in water, they will each of them ſhoot again ſeparate, and in their reſpective figures, not mixing and forming different figures, as might be expected.

This experiment holds good alſo, not only in theſe ſalts, but in all other kinds, which have naturally their determinate figures: thus, if in a veſſel of water, there be diſſolved together ſome blue vitriol, ſome roach alum, and ſome ſalt petre, the whole liquor will be of a blue colour from the vitriol; but when it is carefully evaporated to a proper ſtandard, the ſalts will all form themſelves again into their own regular and natural cryſtals: the vitriol will be blue as before, but all the reſt, though found in a coloured fluid, will be as colourleſs as at firſt, and each will have its own determinate ſhape. Though the lixivial ſalt of every plant thus treated, have its own peculiar figure, when diſſolved, and regularly ſhot again; yet, as in the ſea ſalt, and ſome other natural ſalts, there appear, on cryſtallization, maſſes of different figures, ſo in ſome of theſe the ſame ſalt will have two or three different figures, all peculiar however to itſelf. Two ſorts of cryſtals have been obſerved in the ſalts of the lettuce, the ſcozonera, the melon, and ſome others: three ſorts in the black pepper, and in the flowers of the red roſe; and four ſorts in the ſalts of the roots of white hellebore.

Beſides this diverſity of figures in many of the kinds of ſalts, there is one kind of cryſtals which run through the ſalts of almoſt all the kinds, in a greater or leſſer proportion: theſe are certain cubic grains or cryſtals. It is probable, that theſe are cryſtals of ſea ſalt, which is a ſalt found mixed among many others, and is naturally of this cubic figure in its firſt or ſimple concretions. It ſeems alſo a general rule, that the different parts of the ſame plant form cryſtals of a different figure; for the leaves of laurel form cryſtals very differently ſhaped from thoſe procured from the wood of the ſame tree; and the figures of the cryſtals in the ſalt of the pulp of a gourd are very different from thoſe of the ſalts made from the rind of the ſame fruit. See Tab. of Microſcopical Objects, Claſs 3.

Many ſalts made from different ſubſtances, have either abſolutely the ſame or very ſimilar figures in their cryſtals. The ſalt of the cucumber has a figure very like that of the ſalt of eye-bright; and the ſame form is obſerved in the cryſtals of orange-flowers, endive, liquorice, and many other plants.

In order to obtain theſe ſeveral cryſtals of the lixivial ſalts, determinate and exact in their figures, and not mixing one with another, it is neceſſary to uſe great caution in the evaporating the lye; for if it be totally evaporated, there remains only a cruſt of ſalt at the bottom of the veſſel, if it be only too far evaporated, though not totally: the ſalts ſhoot into large cluſters, and are never regular and perfect; and finally, if the lye is left too weak, then the evaporation afterwards, in order to the forming the cryſtals, is ſo tedious, that few can have patience to attend to it. Nothing but practice and experience can dictate when to ſtop the evaporation; but when this has been learned, the veſſel is to be taken out of the *balneum mariæ*, and the clear liquor is to be poured out of it into ſeveral ſmall vials. Theſe are to be ſtopped to keep out duſt and moiſture; and, after a time, the ſalts will congeal into cryſtals, which will be fixed to the ſides and bottoms of the vials, in their true and proper ſhapes, and in the likeneſs of rock-cryſtal, as to brightneſs and tranſparency.

Different plants and trees yield aſhes, which are impregnated in a different degree with ſalts. The ſame plants, at different ſeaſons of the year, contain alſo different quantities; and all theſe varieties make it neceſſary to attend carefully to the time of ſtopping the evaporation. It is alſo to be obſerved, that there is a great difference in the quantity of aſhes, to which plants and their flowers and fruits burn, as well as in that of the ſalt they yield; and what is moſt remarkable, is, that theſe have no connection one with the other. There are various inſtances of this kind in Redi's paper; he obſerves particularly, that an hundred weight of orange flowers reduced to aſhes, yielded only four pounds ſix ounces of them, and theſe aſhes only five drams of ſalt: that eight hundred weight of gourds made only four pounds of aſhes; but theſe yielded no leſs than ten ounces of ſalt, while an hundred weight of maiden-hair yielded nine pounds of aſhes, and theſe only four drams of ſalt. A great number of other proceſſes of this kind are mentioned in the ſame place; to which we refer the curious.

It was obſerved, that all theſe ſalts thus cryſtallized, had a purging virtue, from whatever plant they were made; and the ſalt drawn from pomegranate peels, or other aſtringents, is as ſtrongly purgative, as that from the moſt purgative drugs. The doſe in which theſe ſalts are to be taken, is from half an ounce to an ounce diſſolved in warm water; and it is all the ſame thing what *Vegetable* they are made from; the ſharp-pointed cryſtals and the blunt ones having the ſame degree of virtue. Garlick, and the like ſhop *Vegetables*, yield no ſalt at all of this kind. Philoſ. Tranſ. N°. 243. p. 296.

VEGETATION (*Cycl.*)—The great attention of all who ſtudy botany, is at preſent placed on the diſcovery of new plants; but we are yet unacquainted with many peculiarities in the moſt common ones, which may prove not a leſs worthy employment for our thoughts.

The irregularities in the *Vegetation* of the ſeveral parts of plants ſeems a ſubject well deſerving our attention; and Mr. Marchand has laid before us an inſtance of this in one of our moſt vulgar plants, the common garden radiſh.

In the month of July, this gentleman obſerved a plant of this ſpecies, which had accidentally fixed itſelf in an open place, and was then full of flowers and pods. Toward the end of one of the branches, he obſerved a kind of tuberoſity of an oblong ſhape, which looked ſomewhat like one of the pods of the plant, but that it was too long, and was very oddly twiſted and contorted; this daily increaſed in ſize, and in a week was come to its full growth, which was, in the whole, about two inches and a half in length, and three quarters of an inch thick. It was of a very rough and knotty ſurface, and like the reſt of the ſtalk, had ſeveral pedicles of flowers growing on each ſide from it; it terminated in a ſmooth end, divided into three parts, which all turned upwards.

The longeſt of theſe points terminated in a green cartilaginous flower of the ſame ſubſtance with the protuberance which produced it; in this there were all the regular parts of the flowers of the more perfect kind; there were four leaves which ſerved for a cup; four more within theſe, which repreſented the petals; ſix other ſmall bodies there ſtood in the middle of the flower, which repreſented the ſtamina; and among theſe another body which repreſented the piſtil; ſo that, here was in this irregular *Vegetation*, a repreſentation at large of every part of the perfect flower of the radiſh, excepting only the apices; but theſe were all very different in their nature and ſtructure, from their ſimilar parts in the natural flowers, being all of a hard, thick, and tough cartilaginous ſubſtance, and in colour of a greeniſh brown.

The ſhorteſt of the three points which terminated this tuberoſity, had alſo at its end a reſemblance of a flower compoſed of all the parts mentioned in the former, and of the ſame colour and ſubſtance with it, only differing in being a little ſmaller: and the third point had no regular reſemblance of a flower, but was of the ſame cartilaginous ſubſtance, and of a ſemi-circular figure, and had its upper ſurface ornamented with ſeveral irregular protuberances. This irregular *Vegetation* remained in vigour till October, when it gradually faded away, and there was no appearance of ſeeds in any part of it. The radiſh, when its ſtalks are wounded by the pucerons, or other inſects, will often throw out a protuberance of ſome irregular figure; but the reſemblance of flowers in this, was a ſingularity never before obſerved.

To explain this, it will be neceſſary to obſerve, that every organized part of a plant contains in it a number of inviſible ſeminal principles, capable of producing plants like that to which they have owed their origin; and this is a truth of which the ſucceeding inſtances will all bring very familiar and obvious proofs.

The graft of a tree, which from only one ſingle bud, produces a tree like that from which it was taken, certainly acts upon this principle; for the whole tree is quite different from the ſtock on which it is grafted, which ſerves for no other purpoſe but merely to convey to it a proper nutritive juice for the developing its parts.

We very well know, that there are many roots, which being cut into little ſlices of only a quarter of an inch thick, each of theſe will propagate its ſpecies, and ſend up new plants, like that which the root belonged to; and ſome roots being ſplit longitudinally into four quarters, each of theſe will in the ſame manner grow and flouriſh, and ſhoot out roots from one part, and ſtalks from another, ſo as to furniſh perfect plants the ſame year: and how can this be, but by their having been ſeminal points in all theſe pieces and ſections of roots, which being dilated, and put in action by the humidity of the earth, have grown into perfect plants. Several of the bulbous rooted plants produce off-ſets from the ſeveral ſcales of their roots, and from the

fides of their ftalks; thefe in three years time produce perfect plants with their flowers; and what are thefe but fo many feminal points ready upon occafion to be developed.

Nothing is fo obvious, as that the flips, or cuttings of trees, when planted in the ground, produce roots in one part, and buds for branches from another, and fo finally become trees, like thofe from which they were cut; and this, though the piece that is planted, has no vifible appearance of any bud in any part of it.

We alfo know, from daily experience, that many plants fhoot out roots from their ftalks as they grow, and that though this ufually happens in places where there is fome folid fubftance for thefe new roots to faften themfelves to, yet it happens alfo in fome plants where there is no fuch ufe for them; and what are thefe roots in a new part of a plant, but the effect of fo many feminal points, ready to grow both into roots and into branches, in all thofe places.

Among the thick and flefhy leaved plants, as the opuntia, and other of the fucculent plants of the Indies, there needs no more to produce a new plant, but to cut off a part of a leaf, and ftick it into the earth, where it will at once take root, and produce a new plant in a very fhort time. A thoufand other inftances of this kind might be given; but thefe may be fufficient to prove, that there are, in almoft all parts of plants, certain feminal points, which, like the plantula feminalis, inclofed in the perfect feed of each, need only humidity, and a proper degree of warmth, to develop and unfold themfelves into perfect plants.

We are not therefore to wonder at the imitation of perfection in any irregular productions of vegetables, fince it appears that there are numbers of perfect plants contained in every part of a growing plant, of the fame kind. Mem. Acad. Par. 1709.

The perpendicular afcent of the branches and trunks of trees, while their roots are at the fame time running perpendicularly downwards, has been a fubject of admiration to all who have confidered the laws of *Vegetation*; and none feem to have well underftood or explained it, till Mr. de la Hire, in the memoirs of the Paris Academy in 1708. He fuppofes that, in all vegetables, the root is furnifhed with juices of a much thicker and coarfer kind than thofe of the trunk and branches, and that the juices of this part are heavy and denfe; while thofe of the upper parts of the fame vegetable are much more light and fine.

In effect, the root of the plant paffes with all naturalifts as a part analogous to the ftomach in animals, where the nourifhment is digefted, and refined to fuch a degree as is neceffary for its being received into the finer and tenderer veffels of the trunk and branches.

This difference of the juices for the fervice of the different parts of the plant, neceffarily fuppofes a different fhape and fize of veffels for its reception, and, in a word, a different contexture in the parts; and there is no doubt but that this contexture is preferved in its different manner, even in the firft rudiments of the plant or tree, in the feed.

We are therefore to conceive, even in this embryo plant, a fort of divifion between the root and the ftalk; fo that all that is to be on the one fide of that divifion, is to receive a finer juice for its nourifhment, and all that is on the other fide, a coarfer. Now fuppofing that the plantula feminalis, or embryo plant in the feed, be turned the wrong end upwards, in the fowing or placing that feed, fo as to have its root turned upward, and its ftalk downward; yet the veffels of the root being larger than thofe of the ftalk, and confequently capable of receiving coarfer and heavier fluids; thefe weighty fluids muft always bend its tender fibres downwards, though their natural pofition in the feed would point them upward; they will always be bent downward alfo by the greater force, the longer they grow. For, fuppofing the fixed point, already mentioned, to be at firft at any given diftance from the extremities of the roots, and they bending downward, it is plain that, as they increafe in length, they will be of more force, as the arms of a lever are always more powerful the longer they are.

While all this is doing in the root, the communication being open between that and the ftalk, the finer juices are received there, and thefe as naturally throw the ftalk into an erect pofture, as the others bend down the root; fo that, in a few days the whole plant becomes turned right, the fixed point between the root and ftalk having remained unmoved, and all on the one fide of it having conftantly had a tendency upwards, while all on the other had the fame tendency downward.

From this time forward the root pufhes with more regularity downward, and the ftalk upward, than before. There is, however, this great difference in their growth, that the ftalk and branches find no refiftance to their fhooting up, while the roots find a great deal to their fhooting downward, by means of the folidity of the earth, whence the branches advance much fafter and farther in their growth than the roots; and thefe laft, often finding the refiftance of a tough earth unfurmountable, turn their courfe, and fhoot almoft entirely horizontally. Mem. Acad. Par. 1708.

Artificial VEGETATION. Many of the proceffes and operations in chemiftry afford productions, whether of falts or metals, or of whatever other fubftance, which very much refemble plants of one kind or other, whence they have been called *metallic Vegetations*. But though many have been hence induced to believe, that thefe productions were formed in the manner of vegetables, there is not the leaft ground for fuch an opinion from reafon or expriment.

Mr. Homberg, who has treated very accurately of the feveral kinds of thefe *chemical Vegetations*, divides them into three different claffes.

Thofe of the firft clafs are fuch as confift of a pure maffy metal, without the mixture of any foreign matter whatever. Thofe of the fecond clafs are compofed of a diffolved metal, which, though it has concreted afterwards, yet retains a part of the menftruum in it: And the third clafs contains thofe which have no metal in them, but are merely compofed of falts, oils, or earths, or of combinations of thefe.

All the productions of the firft kind are made without the admixture of any liquor, and are merely owing to the force of fire. Thefe are of a firm and folid texture, and may be taken out of the veffels in which they were made, without danger of breaking them. On the other hand, the *Vegetations* of the fecond kind are all formed in a fluid, and are all fo brittle, that they are not to be touched without breaking. Of the third kind, fome are formed, or will fubfift at leaft, in the dry air; others are very tender, and are formed only in fluids, the very ftirring about of which deftroys them.

Examples of the firft kind may be feen in the following proceffes: Make an amalgama, with an ounce or two of fine gold or filver, with fix times the weight of pure mercury revived from cinnabar; break the amalgam to pieces, and wafh it feveral times with river water, till it leaves no longer any colour or foulnefs in the water; after this, let it be dried, and, putting it into a glafs retort, diftil it in a gentle fand heat, which fhould be continued two days. The longer the heat is preferved, before all the quickfilver is raifed and carried over, the more beautiful and perfect will the *Vegetation* be. At the conclufion of the operation, the fire muft be raifed to fuch a degree, as to carry over all the mercury, after which, let the fire go out. All the mercury will be found in the receiver, and all the gold or filver will be left in the retort. It will be foft and pliable, and of the moft beautiful colour the metal is capable of receiving; and from the main mafs, at the bottom, there will be thrown out a number of beautiful branches, of different heights, and differently ramified, fo as to reprefent fhrubs or plants. Thefe may be feparated from the mafs at the bottom, and preferved. They really refemble, with great exactnefs, fome forts of vegetables; but when we confider the fortuitous rife of thefe, and the regular organized bodies of the true vegetables, with their manner of explication from the feed, there is but a very faint refemblance to be perceived between the one and the other.

Another of thefe *Vegetations* of the firft clafs, is this: Melt an ounce or two of pure filver in a crucible, and when it is in fufion, caft upon it, at different times, an equal weight of common fulphur in powder. Stir the whole about with an iron rod, and, taking it from the fire, let it cool. Beat the mafs to powder, and put it into another crucible. Set it in a fmall fire, or in a fand heat, to drive off the fulphur in fumes, without running the metal into fufion. As the fulphur rifes into vapour, it will carry up along with it a part of the filver, above the furface of the reft, in form of fine flender filaments, or flat and thin plates, which will remain fixed at their lower end to the mafs out of which they are raifed, and will be very foft and pliable, and extremely bright and gloffy. The filaments will often rife to two inches high in this procefs, and the flakes or plates will be of the length and breadth of a card ufed in play.

A third *Vegetation* of this clafs is the following: Melt together two ounces of filver, and fix ounces of lead. Put the mixture into a copel under a muffle in a furnace, and give fuch a fire as is neceffary to purify filver by the copel. When the filver appears fine, take the copel out of the fire, and leave it to cool. Soon after it is taken from the fire, there will arife out of the furface fome filaments of melted filver, of the thicknefs of a hog's briftle, and of three quarters of an inch high. They are often larger and thicker than this, and not unfrequently emulate the figure of branches of coral. They are ufually hollow within, and are fixed at the bottom of the mafs of the filver.

Of the fecond clafs, of metallic *Vegetations*, is the famous arbor Dianæ, and the feveral other ramifications of metals after folution. See the article DIANÆ *Arbor*, *Cycl.* & *infra*.

The third clafs, that is, of fuch chemical *Vegetations* as contain no metallic matter, the following procefs gives an inftance: Take eight ounces of falt petre, fixed by coals; fet it in a cellar, and let it run into an oil per deliquium: Filtre this liquor, and pour on it, by a little at a time, as much oil of vitriol as will perfectly faturate it. After this, evaporate all the humidity, and there will remain a compact faline mafs, which will be hard, very white, and of an acrid tafte; powder it grofsly, and pour upon it a fufficient quantity of water, in an earthen veffel; the water will begin to evaporate, after it has ftood uncovered

a few days; and, as this is effected, the falt will vegetate in feveral places into branches; thefe will furround the whole furface of the water, and will continue to form themfelves anew as the water evaporates, till it is all gone; after which they will ceafe; but if more water be added to the falt, they will appear again in all their beauty, as that afterwards evaporates.

Another example of thefe faline *Vegetations* is feen in the branched cryftallizations of falts, naturally produced on the fhore of the Spanifh and other feas, and which may eafily be imitated by art: This is no other than a natural confequence of the fea plants growing on the fhore, being, when their leaves are decayed, crufted all over their branches with cryftals of fea-falt, left by the evaporation of the water, which had been left upon them by the recefs of the fea; this procefs being very frequently repeated on them, every wetting leaves a frefh coat of falt over them; fo that, at length, the whole appears a mere plant of falt. Very beautiful fpecimens of this kind are often met with on the fhores; and may be imitated by art by means of fea-falt diffolved in water, and the folution carefully filtred. But, in doing this, it is neceffary to peel off the bark of the plant which ferves for the mould; for as the bark is ufually brown or green, or of fome colour different from that of the falt, it difcovers itfelf too plainly, and takes greatly off from the beauty of the whole.

A third very fingular inftance which Mr. Homberg gives of thefe *Vegetations* is this: He collected about three pints of rain-water from the bottom of an old wooden trough, in which it had ftood about half an hour, after running down from the tiles of an old houfe. This water had fallen in the time of a tempeft, attended with thunder. He had fet this bottle of water, carelefsly ftopped with a piece of paper, in a window, which looked toward the fouth, where it ftood three months. The water had appeared tolerably clear, when it was firft faved; but, by degrees, as it ftood, there fubfided to the bottom a greenifh fediment, of about a quarter of an inch in thicknefs. There was apparently a fermentation in this matter, and it appeared fpongy and cavernous, and had frequently air-bubbles rifing up from it. In the middle of a hot day, in July, Mr. Homberg obferving this bottle, faw that there was no muddy fediment at the bottom, but only a clear and beautiful green *Vegetation*, part of which had alfo raifed itfelf to the furface of the water, and part remained fufpended, in form of flender filaments, in the middle. The extremity of every one of thefe filaments was furnifhed with a fmall round globule, which appeared white and bright as filver, and refembled a fort of fruit at the top of the branch.. On fhaking the bottle about, the whole *Vegetation* difappeared, and the matter of it blended itfelf among the water in a loofe irregular manner. About ten o'clock the next morning, when the fun began to warm the bottle, the *Vegetations* appeared again in their former fhape, and were only owing to fmall bladders of air which, in their rifing from among the green mud at the bottom, drew up long ftrings of it along with them, and appearing in form of fmall round pearls at the tops of the branches. This appearance continues fo long as the fun fhines upon the bottle; after which the bubbles, and their pedicles, gradually fink together, and lie confufedly at the bottom, till the morning fun of the fucceeding day raifes them again in the fame manner from the bottom to the furface. Mem. Acad. Par. 1710.

The moft beautiful of all metallic *Vegetations* is the *arbor Dianæ*, or filver-tree. A great many proceffes for the making this have been publifhed; but fome of them are not found to fucceed, upon experiment; and others are too tedious to follow. Mr. Homberg gives a fuccinct account of the method by which he ufed to make it, and this is never known to fail. Make an amalgam in the cold, with four drams of pure filver, and two drams of crude mercury; diffolve this in four ounces of aqua fortis; mix this with a pint and half of water, and fet it by in a bottle well ftopped. When there is occafion to ufe it, pour about an ounce of it into a little vial; put into this a piece of the bignefs of a fmall pea of the common amalgama, either of gold or filver, made as foft as butter. Leave the vial to reft for two or three minutes; and in that time there will begin to arife a number of little upright ftalks from the ball. Thefe will vifibly increafe in length every moment, and, foon after, will throw out feveral fide branches. Thus, by degrees, the whole will have the form of a little tree; the ball of amalgama will be of a dead whitifh colour; but the trees will be like the brighteft filver. The whole of this beautiful *Vegetation* will be performed in a quarter of an hour: But it is to be obferved, that the liquor which has ferved once, will not do again.

The matter which forms the tree is not formed by the amalgam put into the liquor; but by the firft amalgam which was diffolved in it, the water added afterwards having fo much weakened the diffolvent, that it is not able to keep the matter fufpended, when there is offered any opportunity for its precipitating; and the mercury, thus diffolved, meeting here with mercury undiffolved, quits the diffolvent, and applies itfelf to it; but that not in its own form of globules, but in fuch fhapes as the mixture of filver, and of the falts of the nitrous acid in the diffolvent, determine it to.

This procefs may be varied a great many ways, as to the thicknefs or thinnefs of the branches, and the flow or fpeedy manner in which they are formed, according to the nature of the liquor, and of the amalgama. The weaker the liquor is, the flower will the branches be formed; and they will, in this cafe, be longer, and fewer in number, and by that means the more imitate a tree. On the contrary, when the liquor is too ftrong, the whole furface of the globule of amalgam thrown into it, will, in a few minutes, be covered with a low and fhort tuft of bufhes; and that water, which is ftrong enough of the folution to produce trees upon a thick amalgam, will not be able to produce any thing upon fimple mercury, and but very little upon a thin amalgam. And, on the contrary, that liquor which is ftrong enough to produce a ramification upon fimple mercury, will, on a thin amalgam, produce only a few fhort bufhes; fome yet lower than thefe will be formed by it on a thicker amalgam, and it will, in fine, diffolve the amalgam.

It appears from the whole, that there is in this nothing of true *Vegetation*, but merely a fimple cryftallization in this form. There is alfo another *Vegetation* formed by cryftallization, without the affiftance of mercury; but it is more flow, and wants the beautiful metalline colour of the laft. It is thus performed:

Diffolve one part of fine filver in three parts of aqua fortis, evaporate half the diffolvent, and add to the remainder of it twice its weight of diftilled vinegar, well dephlegmated; fet this mixture by for a month, and at the end of that time there will be found, in the middle of the vial, a tree, in form of a fir, with its branches reaching up to the furface of the water. This is no other than a cryftallization of the diffolved filver, whofe parts have been thrown into this form by the mixture of the falts of the vinegar with thofe of the nitre. This therefore has not the colour of filver, but is white and tranfparent, in the manner of a genuine falt, and makes a very elegant figure in the menftruum.

A third *Vegetation* of the metallic kind is thus performed: Take a quarter of a pound of common white river pebbles, calcine them two or three times over, quenching them every time in water; after this, beat them to a fine powder, and mix them exactly with twelve ounces of falt of tartar. Melt the whole in a ftrong fire, and let it cool, it will be a vitrified mafs. Powder it, and lay it on a marble in a cellar, it will diffolve into an oil per deliquium: Keep this in a vial; then take any metal you pleafe; diffolve it in aqua-fortis or aqua-regia; evaporate the diffolvent, and there will remain a grey powder. When you have a mind to fee the *Vegetation*, put a fmall piece, about the bignefs of a pea, of this calx into fome of this liquor. In three or four minutes there will iffue out of it a ftalk, which will grow longer and thicker every moment; and finally will fhoot out two or three branches from its fides, and each of thefe, as well as the main trunk, will be terminated by a large round air-bubble.

This is a *Vegetation* extremely different from either of the others. In them the branches were only cryftallizations of the diffolved metal; and the little mafs of matter, thrown into the liquor, furnifhed nothing to them. In this, the whole is owing to the matter thrown in, and is the mere effect of a fermentation. The calx of the metal yet contains fome acids. The alkaline liquor ferments with thefe; the fermentation indeed is but flow, becaufe the metalline particles envelope the acid falts. But as, in all fermentations, there is air difcharged; fo in this air-bubbles are fent upward from the mafs; but the metalline particles rifing with them, detain them, and make their afcent very flow, while they are compelled to draw up a long filament of the metallic matter with them. The metal is foftened during the time of the fermentation, otherwife it could not be thus drawn up with the air-bubbles; but it immediately hardens again, when out of the ftate of ferment, and becomes able to fupport itfelf in the branched form, even when taken out of the liquor it is formed in.

There is another metallic *Vegetation*, which is formed by merely amalgamating a metal with mercury, without the mixture of any acid liquor. Take three or four parts of mercury, purified by five or fix fublimations, and one part of fine gold or filver; make an amalgam without heat; fet this amalgam to digeft for fifteen days in a flow heat, in a matrafs hermetically fealed; the amalgam will in this time harden, and all its furface will be covered with branches and trees, fome of them rifing to an inch high; the quantity of mercury muft be nicely adjufted in this experiment, for otherwife there will be no *Vegetation*, whether the quantity be too much or too little; and if the veffel be not perfectly clofed, the procefs will fail, though the quantities and the degree of fire have been ever fo well obferved. This *Vegetation* is only made by the fire heating the mercury, and raifing it, in order to its flying off; in which rifing it lifts up parts of the metal with it, and leaves them in that pofture, in the forms of trees and plants. Mem. Acad. Par. 1692.

VEGETATION *of Salts*, a name given by Mr. Petit, of the academy of Paris, to the concretions which falts form, after folution in water, when fet in the air to evaporate.

Thefe concretions always appear round the furface of the liquor, affixed to the fides of the veffel, or arifing above its top, and

and are very different in the different falts, and in moft of them very beautiful.

This gentleman acknowledges that the obfervation was owing to accident; for having fet out feveral fmall veffels full of folutions of falts, in order to obferve the progrefs of their *Vegetation*, he was greatly pleafed and furprized to find this remarkable accident attending them. The firft falt he obferved it in was nitre; but foon after, finding that the folution of fal armoniac did the fame, and that with different-figured concretions, the figures which the reft would affume appeared to deferve an enquiry. He chofe to call thefe figures, not before obferved, *Vegetations*, in the language of the chemifts; not that he fuppofed them to be produced as plants, by a regular afcent of juices, but merely by appofition of faline particles one to another. Thefe are all properly of the third clafs of the chemical *Vegetations*, according to Mr. Homberg's diftinctions.

The feveral falts he chofe to experiment upon, were refined falt-petre, fal prunellæ, fal armoniac, fea-falt, fal ex duobus, or the impregnation of the caput mortuum, left after the diftillation of aqua-fortis, &c.

Thefe falts were diffolved in the feveral following liquors; common water, lime water, white wine, red wine, fpirit of nitre, fpirit of falt, fpirit of vitriol, oil of tartar per deliquium, fpirit of falt, and the volatile fpirit of urine, and mixtures of oil of tartar per deliquium, with fpirit of vitriol, and with fpirit of nitre.

Salt-petre, diffolved in common water, produced *Vegetations* refembling the rugged points of rocks; and the more the water is faturated with this falt, the more beautifully the *Vegetations* are formed: For this purpofe, one part of falt may be diffolved in three parts of water, in warm weather; but in colder weather the proportion of the water muft be increafed to four times, or four and a half, the quantity of the falt.

Salt-petre, diffolved in lime-water, affords the fame *Vegetation*; but the points are finer, and the whole bodies of the concretions fmaller. Wine diffolves a fmaller quantity of falt-petre than water; and though the *Vegetations* are fmaller from this folution, yet every particle compofing thefe is granulated in manner of the furface of a mulberry; and the whole concretions refemble fome of the botryoide mineral bodies in miniature, or grapes thick fet upon the bunches.

Spirit of nitre, and oil of tartar, being mixed together to the point of faturation, and the falt formed by this diffolved in a quantity of water juft fufficient for this purpofe, and the folution expofed in a glafs or earthen veffel to the fun, there are formed concretions of the fame kind with thofe of the common falt-petre diffolved in water, except that they are more fine and more ramified. It need not appear wonderful, that this mixture fhould produce the fame concretions with pure nitre, fince it is well known, that true and proper nitre is the refult of it.

An ounce of crude fal armoniac being diffolved in three ounces of common water, and expofed to the fun, there form, upon the edges of the veffel, *Vegetations* more thick and lefs pointed than thofe from nitre, and more refembling rude maffes of flints thrown confufedly one upon another. This folution being fet out in veffels of tin, the appearances are much altered, the concretions are all of a roundifh figure, and are covered on their outfides with numbers of fine points.

The fame falt, diffolved in lime-water, produces a different fort of concretion; thofe in glafs veffels are compofed of round heads, befet with feveral tolerably large points; and in veffels of other kinds, the concretions vary a little, but always keep the fame general form.

Spirit of falt, and fpirit of urine, mixed to the point of faturation, and expofed in earthen veffels, produce concretions very little differing from thofe of fal armoniac, when they are nicely examined; on a carelefs view, however, they appear very different, the feveral granules they are compofed of being much fmaller than in the common folution of that falt.

It is not ftrange that this mixture produces thefe concretions, as well as the fimple folution of fal armoniac, fince this mixture produces a true and genuine fal armoniac.

Sal armoniac diffolved in white or red wine, and expofed, produces, inftead of thefe roundifh concretions, a fort of oblong ones, fomewhat irregular in form, and granulated all over their furfaces, in the manner of a mulberry. Thefe are faftened to a fort of tails, and by this means are made to refemble, upon the whole, clufters of grapes. This might give perfons of warm imaginations an opinion, that the wine was fhewing itfelf again in the form of the grape, whence it was made; but it is to be obferved, that the flowers of fal armoniac, which rife in the diftillation of the volatile fpirit with falt of tartar, being diffolved in water, produce the fame grape-like clufters. And the common fal armoniac, diffolved in an impregnation of the caput mortuum of aqua-fortis, affords the fame grape-like concretions as when diffolved in wine.

The concretions of thefe falts will form themfelves in the fhade, but they are always much more beautiful when the veffels have been expofed to the fun; they are alfo much fooner formed by affiftance of the fun's heat: It will take a month at leaft to produce good *Vegetations* of either in the fhade; but in the fun, a week, or, at the utmoft, ten of twelve days, will be found fufficient. There are many folutions of falts, however, which have no occafion for the fun's heat to form them. Of this kind are the following:

A mixture of fpirit of vitriol, and oil of tartar per deliquium, being made up to the point of faturation, add fo much water as will be fufficient to diffolve the falt precipitated to the bottom of the mixture; if this folution be fet to *vegetate*, the concretions will form themfelves into a fort of little bufhes: Thefe are very beautiful; but fo many accidents muft concur to their formation, that they will not always appear, even from the fame quantities of the ingredients, managed feemingly in the fame manner.

One of the moft ready and moft beautiful of all the faline *Vegetations*, is that formed by a folution of the falts in the caput mortuum of aqua-fortis, with common water. If a pint of water be put to half a pound of this caput mortuum, and the whole boiled together, that the falts may be diffolved, and the liquor afterwards filtrated, and expofed in an earthen veffel, there will be formed, in about eight and forty hours, *Vegetations* wholly like thofe from the mixture of fpirit of nitre and oil of tartar, except that thefe from the caput mortuum are more ramified and more beautiful. When the folution is expofed in a glafs veffel, they form themfelves on the furface into very beautiful figures of trees, fhrubs, and bufhes; and this not only on the furface, but on both the infide and outfide of the glafs. Thefe can be compared to no known concretions, except to the *Vegetations* of iron, defcribed by Mr. Lemery; they differ indeed in nothing from thefe, but that the *Vegetations* of the metal are of a brownifh colour, whereas thofe of the falt are white.

This impregnation fucceeds beft in dry weather, for in a moift feafon the *Vegetations* form themfelves more flowly, and are much lefs beautiful. Glafs veffels are alfo effential to the *Vegetations* being formed in their greateft beauty; they are never nearly fo beautiful in earthen ones; and even in the former the *Vegetations* fucceed much better in fome forts of glafs, than in others. The caput mortuum of aqua-fortis alfo is very different, from the different diftillations; and all of it does not fucceed alike in this *Vegetation* of the falt. That which looks lighteft, and of the reddeft colour, feems the beft for this purpofe. An impregnation of this caput mortuum in red wine, produces no *Vegetations*, but only forms a cruft with fmall eminences on the fides of the veffel; and falt-petre, diffolved in the impregnation of this caput mortuum in water, produces a much more beautiful *Vegetation* than that of faltpetre alone; but at the fame time much lefs beautiful than that of the impregnation alone. Sea-falt, diffolved in the fame impregnation, fometimes will produce beautiful *Vegetations*, but fometimes only a rough cruft. Common rough falt-petre forms no *Vegetations*, but only crufts over the veffel, as is the cafe with the folutions of many of the metals in different acid menftruums. And the fame is the cafe in regard to many falts from which it might be natural to expect concretions of this kind. Memoirs Acad. Par. 1722.

VEGI, or UGI, the names given by the Arabian phyficians to the acorus. Thefe writers feem not to have been acquainted with the plant itfelf in its growing ftate, but only to have known that part of it which was ufed in medicine in their time; but the Greeks defcribe the plant in fome fort.

Serapion mentions the *Vegi* or *acorus* as a medicine; but he quotes no one Arabian who has named it, but tranfcribes his account of it from Diofcorides; and Avifenna fays it is the root of a plant much refembling the alburdi, that is, the paper-reed of the river Nilus. Avifenna adds, that the acorus grows only in wet places; and the old manufcripts of Diofcorides have the epithet *papyraceum* for the *acorus*, though imperfectly expreffed; and thence probably this author took the hint of refembling it to the paper-reed.

VEIENTANA *Gemma*, in natural hiftory, the name of a gem defcribed by Pliny, and faid to be found in Italy; he fays it was black, but furrounded with a circle of white; it was probably a ftone of the camea kind.

VEIN (*Cycl.*)—*Pulfations of the* VEINS. The pulfations of the arteries are well known; but though no fuch motion be natural to the *Veins*, yet there have not been wanting inftances in which a morbid ftate has been able to produce them. The pulfations of the arteries anfwer to the motions of the heart, that throws the blood into them; but when this fluid has once got into the *Veins*, it ufually returns through them to the heart again in an uniform and equable motion; and this is not only the cafe in the human body, but alfo in other animals, whether they be in health or in ficknefs. One of the inftances in which the contrary has been obferved, and where the *Veins* have had a pulfation, is a cafe related by Mr. Homberg to the Paris Academy. The patient was a lady of about thirty-five years old, afflicted with a grievous afthma, a pain in the head, a continual want of reft, and terrible palpitations of the heart.

On opening her body after death, the heart was found of twice its natural dimenfions, its cavities very large, and its fides very thin; and in each trunk of the arteries there was a flefhy polypus fixed to their internal furface. That in the trunk of the

the aorta was found to be two foot long, and plainly of a fibrous fleshy substance, for six or seven inches of its length; but from that downwards, it became only like clotted blood.

At the time that this lady was most violently afflicted with her asthma, the veins of her arms and neck were plainly perceived to have a pulsation wholly like that of the arteries, and plainly followed the motion of the heart: She had, in the latter time of her life, usually two of these fits in four and twenty hours; and when they were over, the pulsations in the *Veins* ceased. Mem. Acad. Par. 1704.

VEINS *of plants*, a term used by Dr. Lister, to express certain vessels in plants, which are analogous to the *Veins* of animals, and have been observed in some degree, by the naturalists of almost all ages, though differently described by authors. Pliny has described these parts of a plant under the names of *venæ* and *pulpæ*; and Dr. Grew calls them *fibres* and insertments on the ligneous body, interwoven with that substance which he takes to be the cortical body, that is, the several distinctions of the grain. This author also calls them the pores of the ligneous body; but that they are not merely such, may be plainly seen in cutting off a transverse piece of the stalk of some large wild plant, as the great wild angelica, or the like. In the cut stalk of this plant, the *Veins* every where shew themselves to be distinct from fibres, observable in the parenchyma of the same cortical body with themselves, the milky juice always rising beside the fibres not in any fibre: also in a transverse cut of the root of the common burdock, the like juice springs on both sides of the several radii of the woody circle, that is, in the cortical body, and the pith only.

Again, where there is no pith, there is none of this juice to be observed, and consequently none of these *Veins*, as in the roots of plants, and trunks of trees, but even in the bark of either. The sphondylium, the cicutaria, and many of the thistle kind, are instances of this. Dr. Grew describes pores in the cortical body, and pith; but these vessels are not of the number of the things designed by those pores; these pores are extended by the breadth of the plant; but the pores of this juice are extended lengthwise. The pith of a dried fennel stalk will shew these very beautifully, and with due care, they may be traced all along the whole length of that pith.

It remains therefore, that if these are pores, they must be of those pores of the cortical body, that are supposed to be extended the length thereof; but it is much more proper to call them *Veins*, or vessels, analogous to those of the human body, and covered with their proper membranes; for they are to be found in the pith, and sometimes in the cortical body of the plant, not included within the common tunicle of any fibres, but having their own proper membranes; which indeed, if they had not, the porous and spungy parts of the pith and cortex would be in all places filled alike with the juice; but on the contrary, it is found to rise in a few set and determinate places only, that is, according to the disposition and order of the vessels. If a ligature be made on the trunk of the spurge, and the trunk wounded, the juice bursts immediately out in large quantities; but if not wounded, none is discharged by means of the ligature: now the exterior part of the trunk of these plants is allowed by all observers to be perforated in almost innumerable places; and therefore, if this milky juice were not contained in its peculiar vessels, there is nothing to hinder, but it should rush out at these pores on the ligature made above; but it is evident, that it does not do this till the containing vessels are wounded.

The juices of plants are probably then all contained in these *Veins*, or distinct and proper vessels, covered with their own membranes, and not loosely distributed through the substance of the plants. Those things which are essential to *Vegetation*, are alike allotted to all plants; and it is to be supposed, that all plants have these vessels, though we cannot alike distinguish them in all. Those plants, whose juices are white or yellow, or of any other colour different from that of the body of the trunk, are always distinctly seen, pouring out those juices at separate holes in a wound. Those whose juices and stalks are of the same colour, do not so readily shew them; but there is a time, when they are, in some parts of these plants, if not in all, sufficiently plain to the naked eye.

The tender shoots of the greater and lesser maple, in May, are full of a milky juice, which is the known liquor of these *Veins*; and if a clean knife-blade be applied to a transverse cut of a young shoot of elder, and then raised gently away, the liquor of those *Veins* will be drawn up into strings, answering to the orifices of the *Veins* made by the wound. The pedicles of the leaves of our garden rhubarb, frequently shout out a fort of white and transparent gum: this must be an accidental exsudation of a gum, very constantly contained in the *Veins* of the plant, though not distinguishable in these stalks: this, and many other like instances, prove the existence of such vessels, though they are not obvious to the eye; and there remains no doubt but they are to be found in all plants by some trials. Even the mushrooms, the lowest class of plants, are not destitute of these vessels; there is one which shews them very evidently, this is the wood mushroom, whose stalk, when broken, or cut, discharges a milky juice, as hot as pepper, or more so; and this does not exsudate from the whole spungy substance of the stalk, but is plainly discharged from the mouths of certain wounded vessels.

The primary use of these *Veins* is certainly to carry the nutritious juice of plants; and this appears plainly in that where they are not, there is no vegetation, as is seen if an engrafted branch or arm is bared, or the clay stripp'd off; in this case, all the course of the vegetation will appear to have been made only by the bark, the wood having had no share in it. The bark is the place where these *Veins* lie, not the wood; and therefore, it is no wonder that the vegetation, if dependant on these *Veins*, is carried on only where these *Veins* are. The vegetable drugs of our shops are all of this nature, the juices contained in these *Veins* being evidently what give them their virtue. Phil. Trans. N°. 79.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brownhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes full of all colours. When it bears ore, it is called a *quick vein*; when no ore, a *dead vein*. *Houghton*'s Compl. Miner, in the Explan. of the terms.

The *Veins* of Mines differ greatly from one another in depth, length, and breadth; some stretch obliquely, from the surface toward the central parts of the earth; and these the miners call deep *Veins*; others lie shallow, and circular, so as to encompass a large space; and these are termed spreading *Veins*; others possess a great part of the space they lie in, both in length and breadth; and these are called accumulated *Veins*, being no more than a space possessed by a large group of fossils of one kind. To give the compleat history of *Veins*, and fibres which are smaller *Veins*, their differences, their directions, their interstices, their discontinuations, their risings and fallings, and their goodness, would be a large work. Let it be observed, however, that these things seem all to proceed in a certain order, though that order, and the laws and rules of it, are not perfectly understood, so as to afford sure directions for practice; whence it sometimes happens, that after a *Vein* has been successfully traced for some time, it dips, breaks off, or takes a different course, leaving the workmen as it were at a fault.

When the *Vein* is found, a pit is to be sunk upon it, and a crane fixed at the top of the pit for craning up the ore. Burrows, or adits, are also to be cut horizontally through the hill in one or more places, reaching to the mine, and serving to wheel out the ore, instead of craning it up. *Shaw*'s Lectures, p. 246.

The manner of digging varies according to the nature of the *Vein*. If this be soft, it is dug with the spade, and turned out into wooden trays, placed to receive it. If the *Vein* be harder, it is to be knocked out with the hammer and chissel. If it be too hard for this method, they soften it by fire, which makes all stones brittle; but the most expeditious of all mine working, is that by gunpowder, which tears up, and breaks to pieces vast rocks in a moment.

VELITIS, in the natural history of the antients, the name of a peculiar sort of sand used in the making glass.

The antients, in their different ages, made glass of different materials. These, however, were principally thin natrum, which was, in most respects, the same thing with our alkali salts used in glass-making, mixed with flints, shells, or sand. Sand was the most universal mixture; and for this purpose, they always chose such sand as was found washed clean on the banks of rivers; and this they therefore called glass-sand, or *Velitis*, or *hyalitis*. *Hill*'s Theoph. p. 11.

VELLA, in botany, the name of a genus of plants; the characters of which are these: The perianthium is of a cylindric figure, and erect, and is composed of four slender and obtuse leaves, which fall with the flower; the flower is composed of four petals, and is of the cruciform kind; the petals are of an oval figure, and of the length of the cup; the stamina are six filaments of the length of the cup, only two of them are a little shorter than the other four; these two stand opposite to one another; the antheræ are simple; the germen of the pistil is oval; the style is conic; the stigma is simple; the fruit is a globose, cristated, pendulous pod, containing two cells, divided by a membrane, twice as large as the pod itself, and of an oval figure; the seeds are roundish. *Linnæi* Gen. Plant. p. 317.

VELLIA, in zoology, a name used by some authors for the *lanius minor*, or *lanius tertius* of Aldrovand, called in England the *flusher*. *Ray*'s Ornithol. p. 54. See the article FLUSHER.

VELOCE, in the Italian music, is used for quick.

VELOCISSAMENTE, or VELOCISSIMO, in the Italian music, is used for very quick, or with great rapidity. It is seldom met with; *presto*, or *prestissimo*, being mostly used in its stead. *Brossard*.

VELOCITY, (*Cycl.*) — In the doctrine of fluxions it is usual to consider the *Velocity* with which magnitudes flow, or are generated. Thus, the *Velocity* with which a line flows, is the same as that of the point, which is supposed to describe or generate the line. The *Velocity* with which a surface flows, is the same as the *Velocity* of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The *Velocity* with which a solid flows, may be measured by the *Velocity* of a given plain surface, that

that by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The *Velocity* with which an angle flows, is measured by the *Velocity* of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. See *Mac Laur.* Fluxions, B. 1. ch. 1.

All these *Velocities* are measured at any term of the time of the motion, by the spaces which would be described in a given time, by these points, lines, or surfaces, with their motions continued uniformly from that term. *Mac Laur.* ibid.

The *Velocity* with which a quantity flows, at any term of the time, while it is supposed to be generated, is called its *fluxion*. See the article FLUXION.

VELVET (*Cycl.*)—*Colour of black* VELVET: The manner of giving this deep and fine colour to glass, is this: Take of crystalline, and pulverine frit, of each twenty pounds, of calx of lead and tin four pounds; set all together in a pot in the furnace, well heated; when the glass is formed and pure, take steel well calcined and powdered, scales of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well; then put six ounces of this powder to the above described metal while in fusion; mix the whole thoroughly together; and let all boil strongly together, then let it stand in fusion twelve hours to purify, and after this work it. It will be a most elegant *Velvet* black.

There is another way of doing this, which also produces a very fair black. It is this: Take an hundred weight of rochetta frit, add to this two pound of tartar, and six pound of manganese, both in fine powder; mix them well, and put them to the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it. *Neri's* Art of Glass, p. 95, & *seq.*

VELUM, in ecclesiastical writers, the same with what is otherwise called *brandeum*. See the article BRANDEUM.

VELUM *quadragesimale*, a veil, or piece of hangings, antiently drawn before the altar in *Lent*, as a token of mourning and sorrow. *Blount.*

VENABULUM, in antiquity, a long kind of spear used in hunting wild beasts. *Hofm.* Lex. Univ. in voc.

VENCU, in botany, the Chinese name for an excellent fruit found in that country, which the Portuguese call *jamboa*, and the Dutch *pompelnioes*: It grows on prickly trees, like the limon-tree, only larger. Its flowers are white, exactly the same in shape with those of the limon, and have an exceeding sweet smell; a very fragrant water is distilled from them. The fruit itself far exceeds the citron in bulk, being in size equal to, and sometimes exceeding a man's head. The rind is like that of the golden rennet; the pulp is of a reddish colour, and its taste partakes of sweet and acid, resembling that of grapes not fully ripe. A liquor is pressed from it, as in Europe, from apples, pears, &c. It will keep for a whole year. *Hofm.* Lex. Univ. in voc.

VENDITOR *regis*, the *king's salesman*, or person who exposed to sale, goods and chattels seized or distrained to answer any debt due to the king. This office was granted by king Edward I. to Philip de Lardimer, in the county of York, *Ita quod ipse, vel certus suus attornatus, ibit ad mandatum vicecomitis de loco in locum infra com. præd. sumptibus suis ad venditiones faciendas, & capiat de unaquaque venditione pro feodo suo* xxxii. Den. but the office was seised into the king's hands for the abuse thereof. Anno 2 Ed. 2. *Blount.*

VENENUM *cocci*, a term used by many of the antients for the purple tinge, which the kermes berry, as it is usually called (see the article KERMES) gave to linnen, or other things.

The word *Venenum* being generally understood to express poison, it has been supposed by many, that the kermes was esteemed poisonous, or that there were two sorts of this drug; the one a harmless medicine, and the other poisonous. But there is no warrant for this in any of the old writers, and the whole seems indeed but a mistake about the sense of the word *Venenum*, which we find by many passages of the best authors, signified a stain, as well as a poison.

The antients called the vestments dy'd scarlet with the kermes indifferently, by the names of *flammeæ*, or *venenatæ*. Servius tells us, that in certain sacred ceremonies, it was necessary that the priest should be clothed in a scarlet robe; and he uses the word *venenato* to express it in some places, and *flammeo* in others.

VENER, one of the many names by which the chemists call Mercury.

VENEREA *concha*, in natural history, the name of a very large and elegant genus of shells, more usually called the *porcellanæ*. See the article PORCELLANA.

VENETA *bolus*, a fine red earth used in painting, and called in the colour-shops *Venetian red*.

It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight astringent taste, and makes no fermentation with acids.

It is dug in Carinthia, and sent from Venice into all parts of the world, being an excellent colour, and very cheap; our colour-men, however, find too many ways of adulterating it. *Hill's* Hist. of Fossils, p. 59.

VENISON, *Cycl.*—The old huntsmen have determined, that every beast of the forest, that is food for man, is *Venison*. In many parts of the world, the bears are as regularly hunted, as the hare and buck, &c. are with us, and there are called *Venison*; but with us, at present, the word *Venison* seems limited to the flesh of the hart, the hind, the buck, the doe, and the other creatures of that kind.

Some have extended the signification of the word to the beasts of the forests, which were chased as game, and afforded the diversion of hunting, whether their flesh were eaten or not; thus, in some places, the wolf and the fox are reckoned among the *Venison* beasts. See the article FOREST.

VENOSA *arteria*. See the article ARTERIA *venosa*.

VENOSE *Leaf*, *Venosum folium*, among botanists. See the article LEAF.

VENTININA, a term used by Paracelsus and his followers, to express the art of divining, or knowing by the winds and their courses, the good or ill effects of seasons.

VENTRICULUS *succenturiatus*, in medicine, a name given by some to the duodenum, when very large. Medic. Ess. Edinb. abridg. Vol. 2. p. 34.

VENUS (*Cycl.*)—A smaller star having been observed by Mr. Short near *Venus*, which had the same phasis as that planet, has given some suspicion of its having a satellite. See Phil. Trans. N°. 459. sect. 23. where it is said, that M. Cassini, in his Elemens d'Astronomie, mentions a like observation.

VER-*puceron*, in natural history, a name given to a kind of insects which are fond of eating the *puceron*, and destroy them in vast numbers. See the article PUCERON.

They are thus called, as the ant-eater is, *formica leo*, from their destroying great numbers of them.

These *Ver-pucerons* are a sort of worms produced from the eggs of flies, and are of two principal kinds; the one having legs, the other none.

When we observe the vast number of young produced by every puceron, and the quick progress they make in their multiplication, we are apt to wonder, that every plant and tree in the world is not covered with them; but on the contrary, when we observe the devastation these devourers make among them, we are apt to wonder how any of them escape at all, to perpetuate the species. These worms indeed seem created for no other purpose but to destroy them; and this they do in so violent a manner as is scarce to be conceived. As the flies of many kinds lay their eggs on meat and other substances, which they know will afford food for the young ones, when hatched from them: so the parents of these worms lay their eggs on the branches and leaves of trees loaded with pucerons, on which they know they will feed. The worms produced from them are devourers from the very instant they are hatched, and find themselves placed in the midst of prey, being every way surrounded by a nation of creatures which are their proper food, and which are furnished with no weapons, either offensive or defensive, and which never so much as attempt to fly from them, but seem wholly ignorant of their danger, till seized upon by the devourers. *Reaumer's* Hist. of Insects, Vol. 6. p. 111.

These worms are very large in proportion to the pucerons, the difference not being less than that between the lion and the smallest quadruped. Their figure is varied at pleasure; but seems, in its most natural state, to be much larger at the posterior part than at the anterior; the posterior part also usually remains fixed, while the other is twisted about various ways; but the creature can, at its pleasure, shorten the body, by drawing in the several rings, and then it appears of an oval figure.

These worms are of different colours, and different species; those which are found on the elder are green, with a white ray down the back; those on the sloe and gooseberry-tree are whitish, variegated with yellow undulations. Other species are of a pale yellow, others of a somewhat deeper yellow, with two streaks running down their backs of a bright chesnut colour, between which there is one black one. Some have reckoned these several species among the caterpillars, but very improperly, as they have no one character of this kind, but every way resemble the worms or maggots, produced from the eggs of the common flies. These creatures have at their head a dart of a brown colour and hard substance, ornamented with two smaller points at the base, so that it represents, in some degree, a flower-de-luce: this is the weapon with which they destroy the pucerons, and this they either draw back within the head, or thrust out at pleasure. The mouth of the creature is placed under this dart, but is not easily discovered, the creature usually keeping it very closely shut; there are times however, when the creature is seen bending its head down several times towards its belly; and if the anterior and under part be then examined, the place of the mouth will be distinguished by means of a yellowish liquor which it throws out of it.

All these worms have two stigmata or apertures for the receiving air at the hinder part of the body. These are very distinctly

ſtinctly ſeen, and are either round protuberances, placed at the two ſides of the upper part of the ring; or two tubes or cylinders, either ſo placed or joined together, and elevated above the reſt of the ſurface. They have alſo two ſtigmata near the head; theſe are called anterior, as the others are poſterior; but theſe are ſmaller than the others, and have been generally overlooked by authors. There are ſeveral ſpecies of theſe worms that are hairy, and ſome are prickly. One very ſingular ſpecies is ſo much ſo, that it reſembles a hedge-hog; it is of a greeniſh white colour, but has three lines running along the back, compoſed of three ſeries of ſpots, thoſe of the middle line being black, and thoſe of the others brown. The ſpines or prickles upon this ſtand in the number of ten or twelve on every ring, and are all hooked, and have their points turned toward the hinder part of the body. They only are placed on the back and ſides, the belly being perfectly ſmooth. See Tab. of Inſects, N°. 24.

Theſe creatures have no legs; there are indeed certain fleſhy eminences on the under part of the rings of ſome of them, which aſſiſt them in walking; but their common method of moving is by fixing their head to any part, and then drawing the reſt of the body to it. This creature, however, has very little occaſion for motion; its whole buſineſs, in this ſtate, is to eat, and its parent has ſo placed it, that it need not hunt its food ſingly, like other creatures of prey; but it finds itſelf every way ſurrounded with the creatures it is to feed upon, and touched by them before, behind, and on every ſide; nay, they often walk upon its back without any apprehenſion of the danger: They remain in their places till he has cleared them away, by eating them; and when he has devoured all within his reach, it is then only that he need move his quarters, and that but a little way; for he ſeldom has farther to go than to the fartheſt place his head could reach, while he remained fixed in the former place. *Reaumur*'s Hiſt. Inſ. vol. 6. p. 117.

The way to ſee him eat, ſo as to diſtinguiſh the manner of it, is to keep one a few hours without food, and then placing him on a paper, or on the hand, and placing ſome of the pucerons about him, the manner of his feeding on them will be ſeen. It appears evidently that he has no eyes, for he tries to find them only by feeling, ſtretching out his head, and trying every where with it, before, behind, and on every ſide, while his hinder part remains fixed. As ſoon as he perceives a puceron, he darts his triple weapon into it, and ſticks it juſt as we do a mouthful of meat upon a fork; he then draws back the dart into the firſt ring, and that ring into the ſecond, and then uſes his mouth, which has a kind of trunk, with which he ſucks the juices of the puceron.

When the *Ver-puceron* is of the white, or otherwiſe pellucid kinds, it is a very ſurpriſing ſight to obſerve the manner of the feeding, which is clearly ſeen through the ſkin. The puceron being drawn into the ſecond ring of the body, there is ſeen juſt below that an oblong body, which is, at times, darted up to the body of the puceron, and down again from it. The movements of this are very ſwift, and the ſpace of reſt between them but ſhort. This is a ſort of pump, which ſucks in the parts and juices of the animal, and delivers them again to the œſophagus or ſtomach, placed behind it. During the ſhort ſpace of reſt, we ſee it diſtinctly diſcharge from its hinder part what it had before received from the animal, into this paſſage. This is ſometimes only its juices, which look like ſmall bubbles of air, and ſometimes a great number of little roundiſh granules, which are evidently the embryo pucerons, with which we know the body of all the grown ones to be loaded, all the pucerons being breeders.

When the worm is hungry it feeds very voraciouſly, when not ſo, it eats more at its leiſure. The ſkin of the puceron is always thrown out of the mouth, as ſoon as its juices and entrails have been ſucked, and it then looks perfectly like the exuvia, which the pucerons naturally throw off when they change their ſkins. The worm will ſuck one of theſe creatures thus dry in leſs than a minute, and then loſes no time, but throws it out, and immediately ſeizes another. In this manner Mr. Reaumur ſaw one worm eat twenty of theſe creatures in twenty minutes, and ſuppoſes that he continued the ſame ravage long afterwards; for having put him among an hundred pucerons, there was not one left after two or three hours.

When the worm is placed at its eaſe among vaſt quantities of them, it does not eat ſo very quick, but ſeems to amuſe itſelf by eating one in two or three minutes. This manner of feeding, however, deſtroys prodigious numbers, for they ſeldom reſt, but are almoſt continually at it; and it is hard to find one of them, at any time, without a puceron in its mouth. So that a branch of elder, which is covered on every part with theſe animals for four or five inches, ſhall be found wholly cleared in three or four days, by only three or four of theſe worms. *Reaumur*'s Hiſt. Inſ. vol. 6. p. 127.

The pucerons are never free from their enemies; there is no place where they are ſeen in any conſiderable number, where theſe worms are not alſo found; and their ſecureſt retreats do not preſerve them. The bladders of the elm, and other trees; the galls of the leaves and pedicles of the poplars, and the folded leaves of the ſame trees, which are all inhabited by the pucerons, are all ſubject to be viſited by theſe worms alſo. They do not always immediately make their way into them; but as ſoon as one of the winged pucerons has eſcaped out of the place, the hole at which he came out, lets in one of theſe worms, which ſoon deſtroys all the remainder of the family. Another great misfortune to theſe poor creatures, is, that the worms are not confined to any one ſpecies of them, but eat all indifferently.

The anus of the worm is placed in the fold of the two laſt rings of the body, and is almoſt continually voiding a blackiſh liquid excrement.

Theſe worms, when full grown, are greatly an over-match for the pucerons; and it is odd to obſerve the young worms in their attacks upon them. A worm juſt hatched, and not a third part ſo big as the puceron, will immediately, however, attack any one that is next it: The puceron, feeling itſelf wounded, will immediately run away; but the worm keeps its hold, and, raiſing its body by the head, ſticks to the puceron, and even kills and ſucks its juices while it is carried away. When it has done with this, it gets upon another, and ſo on, till it grows and gains ſtrength and ſize enough to reſiſt the force of the puceron, in endeavouring to carry it away, and then fixing itſelf by the tail among the heaps of them, it feeds at pleaſure. When it has eaten till it has arrived at its full growth, the time of its transformation into the fly ſtate approaches: It then ceaſes to eat, and crawling along the leaf or ſtalk of the plant, ſeeks out a proper place where it may be at reſt during its cryſalis ſtate.

When it has pitched upon the place, it begins to void the viſcous liquor before-mentioned in great quantity from its mouth. It extends this over a ſpace equal to its body, and then placing itſelf on the place, it becomes fixed there, and moves no more. It draws back its head, and the ſkin of the whole body hardens ſo as to form a ſhell, under which it paſſes the cryſalis ſtate. In this ſtate it makes a very beautiful appearance; for the ſkin, though become as hard as horn, yet has loſt nothing of its tranſparence, but, on the contrary, has gained a yet greater degree of it; and the nymph of the fly is ſeen clearly within it, the motion of the heart being very diſtinctly viſible.

After this, as the nymph grows every day more and more perfect, the eyes, the antennæ, and the ſeveral other parts, may be diſtinctly ſeen: And this indeed would prove the beſt of all ſubjects to convince thoſe who ſuppoſe, that maggots are ſuddenly changed into flies, and caterpillars into butterflies, of the error of their opinion; as they might here ſee, by the cleareſt occular demonſtration, that the change is very ſlow and regular.

The flies which are produced from theſe worms, are all of the two-winged kind; but there are ſeveral different ſpecies of them; the generality of them reſemble waſps, and have a very flat body. Goedart, who has deſcribed ſome of theſe flies, was ſurprized to ſee them very ſmall, when firſt produced from the cryſalis, yet growing very large in a quarter of an hour's time, and that without taking any nouriſhment; but this was only owing to their ſeveral parts having been greatly ſqueezed while in the cryſalis, and expanding themſelves when they were at liberty from the compreſſion. Theſe are the changes of this kind of *leo puceron*; but the other devourer of theſe creatures, which has ſix legs, is of a different kind, and indeed is in itſelf reducible to ſeveral ſpecies, ſome of theſe ſix-legged worms becoming four-winged flies, and others a kind of beetles. Theſe, from their near reſemblance to the formica-leo, are by Reaumur diſtinctly called *puceron-lions*. *Reaumur*, Hiſt. Inſ. vol. 6. p. 131. See the article Puceron-*Lion*.

Ver *Polipe*, in natural hiſtory, a name given by Reaumur, and ſome other authors, to a ſpecies of water-worm, by no means to be confounded with the creature called ſimply the *polype*, and which is ſo famous for its reproduction of parts cut off, and for many other ſingular properties. See the article Polype.

This *Ver-polype* is a ſpecies of water-worm, produced from the egg of a tipula, and had this name given it from ſome remarkable productions, placed at the anterior and poſterior parts of the body, which are ſuppoſed to have ſome analogy with the parts of the ſea-fiſh called the *polypus*.

Theſe worms are found in muddy ditches, uſually either crawling upon, or buried in the mud. They are of various ſizes, from more than an inch in length, to a fifth of an inch, and are ſmooth and even on their ſurface; they are compoſed of ſeveral rings, as other inſects of this kind, and have a brown ſcaly head, of a regular figure, and much harder than the reſt of the body. Juſt below the head, on the under part of the body, there are placed two membranaceous productions, which ſeem fragments of arms; they are conſiderably thick, and are cut off obliquely at the ends, and furniſhed with many hairs. At the other extremity of the body there are placed four other productions, reſembling four pieces of cords; two of theſe are affixed to the middle of the lower ſide of the laſt ring but one, and the other two, at the joining of this to the laſt ring. The anterior pair ſerve the creature greatly in its moving, and theſe hinder ones have their uſe in fixing that part of the body in the earthy caſe the creature ſometimes makes for itſelf, while the head is at liberty to move every where about in

fearch of prey. Thefe hinder ones are broadeft at their infertion, and fomewhat narrower at the point, and are very flexile and moveable every way.

The anus of the creature is placed near the end of the laft ring of the body, and is of a fquare figure; it is furrounded with a number of rigid hairs or fpines, and at each corner has a flefhy tubercle, which ftands out a confiderable way from the level of the body; the two under ones are much larger than the other two, and the creature evidently ufes them to pufh itfelf forward in its moving about. Probably, however, thefe parts have fome other more important ufe. The taking in of air or water is likely enough to be the ufe they are affigned for.

The cells which thefe creatures ufually live in are compofed principally of fragments of a light and fpungy earth, and to this they add the broken pieces of fticks and leaves, and other fuch fubftances as are juft heavy enough to fink in water. Mr. Reaumur fufpects that they have a method of fpinning fome glutinous fluid out of their bowels, to fix thefe things together with. But though they ufually refide in thefe cafes, they often quit them, and are found fwimming about the water, or with their tails at the top, and playing about with their bodies; or at the bottom, crawling on the furface of the mud.

When the creature has lived its deftined time in this ftate, it changes into a nymph, in the cafe in which it had lived to the time of this change; it throws off the head, and the productions that ferved as arms, and to faften it at the botttom of the cafe. Nature has generally made the nympth and cryfalis ftate of animals a time of reft and incapacity of motion; but in this, as in the great worms, has given even the nymph a locomotive power, and that a very brifk one. The creature, in this ftate, had fufficient need of it, and could never arrive at its laft change without it. When the time of this final change comes on, the nympth rifes to the furface of the water, and a crack opening on the back, the winged infect begins to appear. The getting thoroughly out is a work of time; and this is the moft perilous period of the creature's life; for if the weather be windy, it is commonly blown into the water, and drowned, before the hinder parts are loofe. *Reaumur*, Hift. Inf. vol. 9. p. 49.

VERANO *Ave*, or *Ave de* VERANO, in zoology, the name by which the Portuguefe in the Brafils call a large bird of the thrufh kind, approaching to the fize of a fmall pigeon, remarkable for its loud noife; and more commonly known by its American name, *guirapanga*. *Ray*'s Ornithology, p. 148. See the article GUIRAPANGA.

VERATRUM, *white Hellebore*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the rofaceous kind, confifting of feveral petals, arranged in a circular form. The piftil arifes from the middle of the flower, and finally becomes a feed-veffel, compofed of three capfules joined together, and containing oblong feeds, fomewhat refembling grains of wheat, and alated or furrounded with a foliaceous edge.

The fpecies of *white Hellebore*, enumerated by Mr. Tournefort, are thefe: 1. The greenifh-flowered *Veratrum*. And 2. The earlier-flowering *Veratrum*, with blackifh purple flowers. *Tourn.* Inft. p. 272.

VERBASCULUM, in botany, a name given by many authors to the primrofe, and with the title of *odoratum* to the cowflip. *Dale*, Pharm. p. 187.

VERBASCUM, *Mullein*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of a fingle leaf, rotated, and divided into many fegments at the edge. From the cup there arifes a piftil, which is fixed in manner of a nail to the middle part of the flower, and finally becomes a fruit or cafe of an oval pointed figure, divided by an intermediate feptum into two cells, which ufually contain a number of fmall angular feeds fixed to a placenta.

The fpecies of *Mullein*, enumerated by Mr. Tournefort, are thefe: The common broad white-leaved yellow-flowered *Mullein*. 2. The white flowered common *Mullein*, called by many the female *Mullein*. 3. The great female *Mullein*, with a large yellow fcented flower. 4. Branched *Mullein*, with narrow thick leaves, and a gold-coloured flower. 5. Black *Mullein*, with a purplifh yellow flower. 6. Annual green-leaved *Mullein*, with yellow flowers. 7. The black *Mullein* of Diofcorides. 8. Black *Mullein*, with leaves like the yellow horned poppy. 9. The powdery *Mullein*, with fmall yellow flowers. 10. The taper *Mullein*, with fmall white flowers. 11. The branched perennial French *Mullein*. 12. The perennial Alpine black *Mullein*, with white flowers, and purple ftamina. 13. Branched *Mullein*, with fmall white flowers. 14. Low perennial Alpine *Mullein*, with leaves and flowers like thofe of borrage. 15. Hoary Alpine borrage-leaved *Mullein*, with white flowers. *Tourn.* Inft. p. 146.

VERBENA, *Vervain*, in botany. See the article VERVAIN.

VERBENA *Femina*. See the article ERYSIMUM.

VERDELLO, in natural hiftory, the name of a green marble, ufed in Italy as a touch-ftone, for the trying of gold, &c.

VERDETUM, the name of a green fubftance, ufed as a colour in painting. It is a very pure kind of verdegreafe, being an ærugo of copper, produced by the vapour of vinegar.

VERDITER *Cycl.*—Mr. Boyle informs us, that the London refiners, to part filver and copper, diffolve the mixture of them in aqua-fortis, and afterwards dilute the faturated menftruum with water, and then with copper plates ftrike down the filver. But as much copper remains in the menftruum; to improve their liquor to the beft advantage, they pour it upon whiting, that is, white chalk or clay finely powdered, cleanfed, and made up into balls, wherewith the tinged parts incorporating themfelves, will in fome hours conftitute a fort of *Verditer* fit for painters, leaving the reft of the menftruum an indifferently clear liquor; whence they afterwards, by boiling, obtain a kind of falt-petre, fit, with the addition of vitriol, to yield them a new aqua-fortis. But he obferves, that fometimes the refiners could not make this *Verditer* for a great while together. But a remedy was found at laft, which is, to warm the menftruum well before it be poured on the whiting. *Boyle*'s Works abr. vol. 1. p. 169.

We have a way of making this colour in England by a mixture of powdered verdegreafe and whiting. This is much inferior to that *Verditer* which is made with the copper-water ufed in the wafhing of filver; but its cheapnefs, and readinefs of preparation at all times, has recommended it into general ufe.

VERDONE, in zoology, the name of a fifh of the turdus or wraffe kind, called by fome authors *turdus viridis minor*.

It is of a fine green colour in all parts of its body; the back, fides, and belly, have all plainly the fame colour; but in fomewhat different degrees, the back being of the deepeft dye; the belly has fomething of yellownefs with the green, and the fides are variegated with lines of a fine blue. It has only one long fin on the back, which has thirty rays or ribs, the eighteen foremoft of which are rigid and prickly, the others foft and flexile. It is caught in the Mediterranean, and fold in the markets in Italy. *Salvian* de Aquat. p. 88.

VERGADELLE, in zoology, the name of a fifh of the mullet kind, called by others the *chelon*, remarkable for the thicknefs of its lips. *Rondelet.* de Pifc. See the article CHELON.

VERITH, in ichthyology, a name given by Ifidore to the fifh commonly called by authors, *thriffa*; by us, the *fhad*, or the mother of the herrings. See the article THRISSA.

It is eafily diftinguifhed from the herring, by the top of the upper jaw being bifid, and the fides fpotted; but it is the opinion of that accurate obferver Artedi, that it differs only in fize from the pilchard, and the agone, alaufa, and fardina, or fmall pilchard.

VERKENS *Vifch*, in zoology, the Dutch name of a fifh caught in the Eaft Indies. It is about feven inches long, of a blackifh-green colour, with fins and tail wholly black, and with yellow irifes to the eyes. It is caught in frefh waters in the Eaft Indies, and is a very delicate fifh. It is very near related to the caprifcus, if not the fame fpecies. *Ray*'s Ichthyogr. Append. p. 1. 3. See the article CAPRISCUS.

VERMELHO, in zoology, the name of an American fifh, more ufually known by the name of the *pudiano*. It is a fmall fifh, of the fhape of the pearch, with a purple back, and yellow fides and belly. *Willughby*'s Hift. Pifc. p. 339. See the article PUDIANO.

VERMES, *Worms*. See the articles VERMIS and WORMS.

VERMICULARIS *Crufta*, a term ufed by fome anatomical writers, to exprefs the internal hairy and corrugated coat of the inteftines.

VERMICULUM, a word ufed by fome chemifts to exprefs a tincture or elixir.

VERMICULUS *Marinus*, the *Sea-Worm*, in natural hiftory, the name of a genus of fhell-fifh of the multivalve kind.

The characters are thefe: They are multivalve fhells, formed in the fhape of tubes or pipes, and are rounded, wrinkled, and ufually crooked, though fometimes ftrait. Thefe fhells are called *vermiculi*, or fea-worms, from the fifh contained in them, which is always a fort of worm. They ufually are found in great clufters together, interwoven oddly with one another.

Bonani calls them fea-ferpents, inclofed in fhells, from the various twifted forms in which they adhere to fhips and rocks. The author eftablifhes them among the multivalves, becaufe they are never found fingle, but always in thefe clufters; in this fenfe he looks upon the whole clufter as the fhell-fifh under confideration, not any one of the fingle tubes: Though he acknowledges that each of thefe tubes is a perfect fhell, independant of the reft, and has its proper inhabitant. Strictnefs in natural hiftory therefore would not bear him out, in arranging them among multivalves, for they are certainly an univalve fhell, though many of them happen always to be found together.

Care muft be had not to confound thefe with the *dentalia* and *entalia*; for thefe laft are always found fingle; and the *vermiculi*, of the kind here treated of, are always found together in great numbers, forming clufters of ten inches, and often much more in diameter.

Of the *Vermiculi*, which are ftrait, we have the following fpecies: 1. The *Tubularia Purpurea*, by many efteemed a fpecies of coral. This is called by fome the *fea-organ*, and has greatly the appearance of common red coral, but is in reality only a mafs of thefe tubes of worms. 2. The pale red *Tubu-*

Tubularia. 3. The thicker *Vermiculus*, called the *great organ-pipe*. 4. The fmooth *Vermiculus*. 5. The ftriated *Vermiculus*. 6. The canaliculated or deep furrowed *Vermiculus*.

Of the crooked kind we have the following fpecies: 1. The gut *Vermiculus*. This fpecies always forms a large clufter, and refembles the inteftines of animals. 2. The varioufly curled *Vermiculi*, 3. The *Vermiculi*, terminating in elegantly twifted ends. 4. The brown wrinkled *Vermiculus*.

Of thofe *Vermiculi* which are difpofed in a fort of circles, we have the following: 1. The earth-worm *Vermiculus*. 2. The concamerated *Vermiculus*. This is a fpecies of *Vermiculus*, divided in the inner part into a number of chambers or cells, in the manner of the nautilus, and having a fiphunculus of communication running through the whole. 3. The mud-*Vermiculus*. This fpecies lies under the mud of the bottom, and adheres to ftones. 4. The oifter *Vermiculus*. 5. The mufcle *Vermiculus*. 6. The buccinum *Vermiculus*. Thefe are three diftinct fpecies, which always take up their abode on thofe peculiar fhells. 7. The red cancellated *Vermiculus*. 8. The brown twifted *Vermiculus*. 9. The rofe-coloured and white *Vermiculus*. Hift. Nat. Eclairc. p. 354.

VERMINA, a word ufed by many of the medical authors to exprefs a tormenting pain in the bowels, feeling as if worms were gnawing them.

VERMIS, *Worm*, in natural hiftory. See the article WORM.

VERMIS *Cæruleus*, a name given by the antient naturalifts to an animal they defcribe as living in the Ganges, and fome other rivers in the Eaft Indies, and of an enormous length. Pliny tells us that they are feventy feet in length; but he at the fame time convinces us, that they were not properly worms; for he tells us they had gills like thofe of fifhes, and fays they were called *Vermes*, only becaufe they were like worms. Ctefias mentions thefe Indian water-worms, and fo do many other old writers, all giving them the fame characters, but differing fomewhat in the length, which the laft-mentioned Greek author makes to be only feven feet, not feventy. Solinus has miftaken this account of the gills of this creature, and has tranflated or copied the authors he took his account from fo ill, as to call them arms, and gives them the length the other authors attribute to the whole animal. This creature was of a blue colour, and lived in the deep waters; but would, according to their accounts, rife up to the furface near the fhore, to feize upon cattle that came to drink. They even tell us of its feizing on the elephant in this manner; and, at this rate, the whole feventy foot length is neceffary. Inftead of feventy feet, fome copies of Pliny have it fixty; and the later authors from this have made it only fix: And Solinus has miftaken what Pliny fays of the creature, being called *Vermis* from its having the fhape of a worm, and fuppofes he means that it was called *cæruleus*, becaufe of its being of a blue colour; but we find nothing of this in the old authors, nor any other name for it but *Vermis*. The naturalifts of late ages have given no account of any fuch animal as this; and it is very probable that the authors who firft defcribed it meant nothing but the crocodile, which they had heard of as a terrible voracious reptile, living in the Ganges, as it does to this day; but had never had any tolerably accurate account of it. See the article CROCODILE.

VERMIS *Cerebri*, the *worm* in the brain, a name given by fome writers to an epidemical fever in Hungary, attended with terrible deliriums.

VERONICA, *Speedwell*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is rotated and divided into fegments at the end. From the cup there arifes a piftil, which is fixed in the manner of a nail to the middle part of the flower, and afterwards becomes a membranaceous fruit, divided into two cells, and containing ufually fmall, but fometimes larger feeds. *Tourn.* Inft. p. 143.

The fpecies of *Veronica*, enumerated by Mr. Tournefort, are thefe: 1. The common fmall procumbent fmooth *Veronica*, called *male Speedwell*. 2. The longer-leaved fmooth creeping Pyrenean *Speedwell*, 3. The upright male *Speedwell*. 4. The broad-leaved fpiked *Speedwell*. 5. The purple fpiked *Speedwell*. 6. The narrow-leaved fpiked *Speedwell*. 7. The long-leaved fpiked *Speedwell*. 8. The fmall fpiked *Speedwell*. 9. The fmall rock *Speedwell*, with naked ftalks. 10. The common meadow *Speedwell*, with leaves like ferpyllum. 11. The fmooth erect Alpine male *Speedwell*, with lightly indented leaves. 12. The fmaller Roman fmooth *Speedwell*, with leaves like the fmall bafil. 13. The fmall creeping *Speedwell*, with roundifh hollowed leaves. 14. Hairy daify-leaved Alpine *Speedwell*. 15. The Alpine fhrub *Speedwell*. 16. The hard fhrubby *Speedwell*, with a long germander-like leaf. 17. The fhrubby Alpine *Speedwell*, with a roundifh fmall leaf. 18. The ever-green rock *Speedwell*. 19. The Auftrian *Speedwell*, with finely divided leaves. 20. The greateft *Speedwell*. 21. The greateft fingle-ftalked not-branched Pyrenean *Speedwell*. 22. The great fhrubby *Speedwell*. 23. The procumbent *Speedwell*, with the appearance of meadow teucrium. 24. The fmaller *Speedwell*, with the lower leaves round. 25. The white-flowered fmall *Speedwell*, with round-bottom leaves. 26. The little narrow-leaved branched procumbent *Speedwell*. 27. The many-ftalked *Speedwell*. 28. The leaft mountain erect, fquare-ftalked *Speedwell*. 29. The creeping *Speedwell*, with teucrium leaves. 30. The common *Speedwell*, with flowers growing to the ftalks. 31. The great round-leaved water *Speedwell*. 32. The fmaller round-leaved water *Speedwell*. 33. The larger long-leaved water *Speedwell*. 34. The fmaller long-leaved water-*Speedwell*. 35. The creeping olive-leaved water *Speedwell*. 36. The narrow-leaved water *Speedwell*. 37. The round-leaved Pyrenean *Speedweed*. 38. The ivy-leaved fpring *Speedwell*. 39. The germander-leaved *Speedwell*, with flowers ftanding on long ftalks. 40. The germander-leaved *Speedwell*, with flowers ftanding on long ftalks, and with leaves placed alternately on the ftalks. 41. The common fpring *Speedwell*, with trifid or quinquifid leaves. 42. The white-flowered annual knot-grafs-leaved *Speedwell*. And 43. The branched upright American fhrubby *Speedwell*, with vervain-like leaves. *Tourn.* Inft. p. 144.

In the Linnæan fyftem of botany, *Veronica* likewife makes a diftinct genus of plants; the characters of which are, that the cup is a perianthium, divided into four fegments, and remaining after the flower is fallen. Its feveral fegments are narrow and pointed. The flower confifts of a fingle petal, in form of a cylindric tube, of the length of the cup, or nearly fo; flat in pofition, and divided into four fegments at its extremity, each of an oval fhape, and the lower the narrower. The ftamina are two filaments, narroweft at the bottom, and bending toward the top. The antheræ are oblong. The piftillum has a compreffed germen; a thread-like ftyle, bent, and of the length of the ftamina; and a fimple ftigma. The fruit is a turbinated and heart-fafhioned capfule, flat at the top, containing two cells, with four valves, and full of a great number of roundifh feeds. *Linnæi* Gen. Plant. p. 4.

VERONUS, in zoology, a name given by many to a fmall river-fifh, well known in England by the name of the minow. *Ray's* Ichthyogr. p. 268. See the article PHOXINUS.

VERSIO *Chemica*, a term ufed by chemical writers to exprefs a change, wrought by their art, of manifeft forms into occult ones, which, they fay, is done by a corruption of the fpecific form, and the generation of a more general one; that is, by a converfion of decompounded elements into compound bodies, and of impure into fuch as are perfectly pure. Theatr. Chem. vol. 1.

VERTEBRÆ (*Cycl.*)—Anatomifts, in the defcription of thefe bones, divide them into the body, apophyfes, and cavities.

The body of the *Vertebræ* is that principal part or large mafs, fituated anteriorly, and fupporting all the other parts. In moft of the *Vertebræ* the body reprefents a portion of a cylinder cut tranfverfely, the circumference of which is more or lefs round on the fore-part, and floped on the back-part. It has two fides, the upper and lower, each of which is, as it were, bordered by a thin lamina, in form of an epiphyfis.

The apophyfes of moft of the *Vertebræ* are feven in number; one pofterior, called the fpinal apophyfis, which ends in a fmall epiphyfis, and has given the name to the whole fyftem of the *Vertebræ*; two lateral, called *tranfverfe apophyfes*, and four others, which are likewife lateral, two on each fide; one above, and one below. Thefe are called by the common name of *oblique apophyfes*, and diftinguifhed into the fuperior or afcending, or inferior or defcending. Thefe four are the leaft of all the apophyfes of the *Vertebræ*, and each of them has a cartilaginous fide. It would be more proper to call them *articular*, inftead of *oblique apophyfes*.

The cavities in the *Vertebræ* are thefe: A large middle hole between the body and apophyfes; four notches, two on each fide, one fuperior and fmall, the other inferior and large. The great foramen is part of the vertebral or fpinal canal; and the notches in one *Vertebra* meeting thofe in another, form the lateral holes which communicate with the canal. The inner fubftance of the *Vertebræ* is fpongy, or like a diploe, covered with an outer compact fubftance; which in the body of the *Vertebra* is very thin, but thicker in the proceffes. The *Vertebræ* are joined together by their bodies, and by their fmall apophyfes. The bodies, in a natural ftate, are principally united by a cartilaginous fymphyfis; that is, by the intervention of a pliable and elaftic cartilage, as is very manifeftly feen in the frefh bones. This cartilaginous connection makes the lateral holes of the fpine larger in the body than they appear in the dry fkeleton, where thefe cartilages are wanting. Their connection, by the fmall apophyfes, is by arthrodia, and not by ginglimus. And thefe two articulations are fecured by very ftrong ligaments. *Winflow's* Anatomy, p. 54.

The cartilages between the *Vertebræ* of the back yield confiderably to the preffure of the body, in an erect pofture, and expand themfelves in the night when perfons lie down. Hence arifes a very fingular phænomenon, but a very true one: which is, that a man is confiderably taller at his rifing in a morning, after the expanfion of thefe cartilages, during the abfence of preffure for feveral hours, than at night, when they have been preffed down all the day.

The reverend Mr. Waffe feems to have examined this difference more ftrictly than any other perfon. He found that feveral perfons, enlifted as foldiers in a morning, had been difcharged for want of height, on their being meafured again

before the officers in the evening; and on this occaſion meaſured ſeveral other people, and found the difference in many caſes to be not leſs than an inch. This gentleman obſerved in himſelf, that fixing a bar of iron where he juſt reached it with his head on getting firſt out of bed in the morning, he could loſe near half an inch in an hour, or leſs, if he employed that time in rolling his garden, or any other exerciſe of that laborious kind. He obſerved alſo, that riding often took off the height very ſuddenly; and what was more particular, that in ſitting cloſe to ſtudy for five or ſix hours without any motion, he loſt often a whole inch in height. People who uſe hard labour, ſink rather leſs in the whole, than thoſe of ſedentary lives; and the height once loſt, is never to be recovered that day, not even by the uſe of the cold bath; but a night's lying down alone can reſtore it. Philoſ. Tranſ. N°. 383. p. 87.

This difference in height takes place only in the human ſpecies, as we are the only creatures who walk erect, and throw the preſſure of our whole weight upon the back-bone. This gentleman meaſured horſes before and after riding, and could find no difference, even after the longeſt journeys.

The alteration in height, is much greater in young people, than in thoſe who are more aged. It is evident from this change happening to perſons when they ſit, as well as when they ſtand, that it is brought about merely by the back-bone; and we muſt admire the ſtructure of that part of the body, which owes its giving way thus, to its being formed together in that manner which alone could ſuit it to the ſeveral purpoſes it was intended for. The thickneſs and ſhortneſs of the bones, with the intervening cartilages, aſſiſted by the bony proceſſes, diſpoſe it to a motion peculiar to itſelf; whereas, had the bones been of any conſiderable length, upon bending the body, the articulations muſt have made a large angle upon their inmoſt edges, and the ſpinal marrow would have been continually liable to be injured; and had the cartilages been intirely wanting, it would have been as uſeleſs as if it were but one bone, whereby the trunk of the body being rendred incapable of bending, muſt have remained for ever in an erect poſture. Another particular, which beſpeaks the utmoſt wiſdom and deſign in the contrivance of this part is, the remarkable difference there is in the cartilages placed betwixt the ſeveral bones of the ſpine.

The *Vertebræ* of the back require but little motion, and the cartilages there are for that reaſon ſmall and thin, in compariſon with thoſe of the loins, which being very thick, the loweſt more eſpecially, the motion is much greater there, and much better to be borne. This being the ſtate and diſpoſition of the parts, during the whole ſpace of time in which we are uſually employed about our ſeveral buſineſſes, till the time that we diſpoſe ourſelves to reſt, the cartilages of the ſpine, will, by their compreſſible and yielding properties, become more cloſe and compact from the preſſure they ſuſtain, and conſequently the ſpine, which is the only ſupport of the trunk of the body, will become ſhorter; but when this ſuperior weight ſhall be intirely removed, by placing the body in an horizontal poſture, as it always is when we are in bed, the compreſſed cartilages will, by their natural elaſtic power, begin gradually to enlarge themſelves, till they, by degrees, recover the expanded ſtate they had before they gave way.

The cartilages between the ſeveral *Vertebræ*, are twenty-four in number, and every one of theſe is preſſed ſomewhat in our daily employments, ſo that when they all come to expand, the aggregate of their ſeveral expanſions cannot be ſuppoſed leſs than about an inch. Now, if this be the difference occaſioned by the preſſure of the common weight of the body alone upon itſelf, it muſt neceſſarily be much greater in thoſe perſons whoſe conſtant employment it is to carry heavy burdens. The compreſſion and expanſion of the cartilages in older people being leſs than in younger, is a neceſſary conſequence of the cartilages in time of age growing harder, and leſs capable of compreſſion; for they often grow almoſt bony in length of time; and hence it is, that old people are obſerved to loſe ſomewhat of their former height, the cartilages in them ſhrinking to a ſomewhat ſmaller compaſs as they grow bony; and this ſhortening is therefore not imaginary, as many have believed, but real, and owing to this plain cauſe. Phil. Tranſ. N°. 383. p. 90.

VERTEBRÆ *fractured*. When any of the *Vertebræ* are fractured without hurting the ſpinal marrow, we may reaſonably ſuppoſe, that the fracture is confined to ſome of the oblique, or ſpinal proceſſes, and therefore the patient will be in no great danger; but when the body of the *Vertebra* is either broke or ſplit, and the contiguous ſpinal marrow bruiſed or compreſſed; all parts of the limbs and viſcera beneath that *Vetebra* become immoveable and rigid, and death often follows. Laſtly, if the tranſverſe proceſſes of the *Vertebræ* are broken, which incline toward the cavity of the thorax, it is ſcarce poſſible, that the heads of the ribs which are connected there, ſhould eſcape being fractured alſo, which makes the caſe very deplorable. When only the proceſſes of the *Vertebræ* are broken, it will be the beſt way to reduce the bones into their places with the fingers, placing narrow compreſſes dipped in warm ſpirit of wine on each ſide the *Vertebræ*, and over them thick pieces of paſtboard, to be kept on by the proper bandages; for by this means the bones of the *Vertebræ*, which are very ſoft and ſpungy, will very quickly and eaſily grow together again.

If in theſe fractures the ſpinal marrow be divided, death is generally an inevitable conſequence; all that the ſurgeon can attempt in this caſe, is to lay bare the fractured *Vertebra* with the ſcalpel, and replace, or elſe remove, ſuch fragments as injured the ſpinal marrow; and the wound muſt be afterwards gently cleanſed, and treated with the vulnerary balſams, to be kept on with the napkin and ſcapulary bandage, till either the wounds ſhall be terminated by a perfect cure, or by death. *Heiſter's* Surgery, p. 125.

VERTEBRÆ *luxated*. The luxations which happen to the ſpine, and *Vertebræ* of the back, are generally imperfect ones; for it appears from an accurate conſideration of the ſtructure, and articulations of theſe bones, that none of the *Vertebræ* can be intirely diſplaced without being fractured, and alſo compreſſing and wounding the ſpinal marrow, which muſt produce danger of inſtant death. Even the imperfect luxations of theſe bones are very dangerous; which happen either between the two ſuperior *Vertebræ* of the head and neck, or between the reſt of the *Vertebræ*, when they are forced from each other. Such as have a luxation between the head and upper *Vertebra*, ſeldom eſcape being carried off by a ſudden death; for by this means, the tender medulla, which joins immediately with the brain, and is lodged in the ſpine, the brain itſelf, and the nerves which ariſe from beneath the occiput, are too much diſtended, compreſſed, or lacerated. The two condyloide proceſſes of the occiput uſually ſlide out of their glenoide ſinuſſes in the firſt *Vertebra* of the neck, when a perſon falls headlong from an high place, or from on horſeback, or when he receives a violent blow upon the neck. People die uſually very ſuddenly by this accident, and are uſually ſaid to have broke their necks, though there is really no more than a bare luxation; though it does really ſometimes happen, that the *Vertebræ* of the neck are broken. If life ſhould remain after ſuch an accident, which very rarely happens, the head muſt neceſſarily be diſtorted, commonly with the chin cloſe down to the breaſt, ſo that the perſon can neither ſwallow, ſpeak, or move any part that is below the neck; therefore, if ſpeedy aſſiſtance is not had, death enſues, from the compreſſure, or hurt of the medulla.

In order to reduce this luxation, the patient muſt be laid flat upon the ground, then the ſurgeon kneeling down with his knees againſt the patient's ſhoulders, muſt bring them together, ſo as juſt to contain the patient's neck between them; this done, he is quickly to lay hold of the patient's head with both his hands, and ſtrongly pulling and extending it, he muſt gently move it from one ſide to another, till he finds by a noiſe, the natural poſture of the neck, and a remiſſion of the ſymptoms, that the diſlocation is properly reduced.

The imperfect luxations of the *Vertebræ* of the back, are no more than their two upper or lower proceſſes being diſplaced, and that often but on one ſide: this happens ſometimes to only one of the ſpinal *Vertebræ*, ſometimes to more. Theſe luxations are generally very difficult to reduce; the beſt method of doing it is thus: When the apophyſes of the *Vertebræ* are diſlocated on both ſides, the patient is to be laid leaning on his belly over a caſk, drum, or ſome other gibbous body; and then two aſſiſtants are ſtrongly to preſs down both the ends of the luxated ſpine on each ſide; by this means the bones of the ſpine will be ſet free from each other, lifted, or puſhed up in form of an arch, and ſo gradually extended: this done, the ſurgeon puſhes down the luxated *Vertebræ*, and at the ſame time nimbly puſhes the ſuperior part of the body upwards, and by this means the luxated bones are ſometimes happily reduced into their places; if ſucceſs does not attend the firſt attempt in this way, the operation is to be repeated. When the *Vertebra* comes out on one ſide, the patient is to be placed inclining in the prone poſture now mentioned; but ſo, that when the left apophyſis is diſplaced, one aſſiſtant may preſs the lower *Vertebræ* inward to the right, and another may depreſs the right humerus, and *vice verſa*. After the *Vertebræ* are reduced, the part is to be bathed with ſpirit of wine camphorated, or to have compreſſes dipped in the ſame ſpirit laid on it, and the napkin and ſcapulary bandage is to be applied. *Heiſter's* Surg. p. 153.

VERTEBRÆ *of fiſhes*.—The *Vertebræ* of fiſhes are extremely different in ſhape in the ſeveral kinds, and even vary in number in the different ſpecies of the ſame genus. The anterior *Vertebræ* in ſome have three apophyſes, as in the cyprini, eſoces, pleuronecti, &c. and in the clupeæ they have no leſs than ſeven of theſe apophyſes, but they are ſlender and capillary. *Artedi* Ichthyol.

VERTIBULUM, a word uſed by ſome writers to expreſs the round head of a bone, which, in its articulation, is inſerted into the ſinus, or cavity of another bone.

VERTUMNALIA, among the Romans, a feſtival celebrated in honour of the god Vertumnus in the month of October. *Pitiſc.* in voc.

VERU, a comet, according to ſome writers, reſembling a ſpit, being nearly the ſame kind as the lonchites, only its head is rounder, and its train longer and ſharper pointed.

VERVA, a word uſed by ſome authors to expreſs an ivory amulet to be worn for the epilepſy.

VERVAIN, *Verbena*, in botany, the name of a genus of plants; the characters of which are these: The flower consists of one leaf, and is of the labiated kind. The upper lip is erect, and divided into two segments, the lower into three; and these are so disposed, that at first sight the flower has not at all the appearance of a labiated one, but seems only divided into five segments. The pistil arises from the cup, and is fixed in the manner of a nail to the lower part of the flower. It is surrounded by four embryos, which afterwards become four slender oblong seeds, which ripen in the cup, and fill it almost wholly up. To these marks it may be added, that the flowers of the *Vervains* grow in spikes, or sometimes in short heads, but never verticillately.

The species of *Vervain*, enumerated by Mr. *Tournefort*, are these: 1. The common *Vervain*. 2. The common *Vervain* with white flowers. 3. The taller broad-leaved Portugal *Vervain*. 4. The fine leaved *Vervain*. 5. The nettle-leaved *Vervain* of Canada. 6. The nettle-leaved *Vervain*, with jagged leaves, and larger flowers. 7. The narrow-leav'd nettle *Vervain*, of America, with blue flowers, and branched spikes. 8. The very narrow-leaved nettle *Vervain* of America, with numerous spikes and purple flowers. *Tournef.* Inst. p. 200. *Vervain* was used among the Antients at their sacrifices, and was thought to contain something divine. The Romans, in the beginning of the year, made a present of this herb to their friends. *Danet.* in voc.

VERVISE, in our statutes, is used for a kind of cloth, Stat. 1 R. 3. cap. 8. *Blount*, *Cowel.* See the article PLONKETS.

VERULCA, the same as *Verva*, a name for an amulet of ivory worn on the arm as a cure for the epilepsy. *Scribonius Largus.*

VERZELLINO, in zoology, the name of a bird common in Italy, and kept in cages for its singing, called by authors *citrinella*, and *thraupis*. See the article CITRINELLA.

VESICARIA, a name given by Rivinus to a genus of plants, the same with the *corindum* of Tournefort. *Rivinus*, 4. 144. See the article CORINDUM.

VESICULÆ *seminales.* These vessels are very evident in fishes; the females of most fish have double ovaria, though in some they are single, as in the osmerus, and perca fluviatilis of Bellonius; but the *Vesiculæ seminales* in the males are two in number in all fish, not excepting the males of these here mentioned. They differ, however, very much in regard to their figure and situation. As to their situation, they in some fish occupy almost the whole length of the abdomen, as in the spinose kinds in general, and in the petromyzum, accipenser, and many of the other cartilaginous kinds. In some fish, they are placed only in the lower part of the abdomen, as in the cetaceous kinds, *&c.* As to figure, in the generality of fish, they are oblong, and compressed, but in some they are round, as in the cetaceous kinds. The other parts of generation are wanting in most fish. *Artedi* Ichthyolog. See the article TESTES.

VESP, or WASP, *Vespa*, in the history of insects. See the article WASP.

VESP-*Ichneumon.* Of this insect, Mr. Ray mentions a great number of species; the greater part of which are common on the sides of mud banks in the borders of fields. These have all slender bodies, and are armed with stings.

The origin of this creature is very strange; it is usually found issuing from the body of the common cabbage caterpillar. The occasion of which is this: The parent fly strikes her tail through the skin of the back of this caterpillar, and deposits her eggs in the creature's flesh. The eggs hatch into small maggots of the carnivorous kind; and these prey upon the flesh of the caterpillar till they arrive at their full growth: the creature that supports them, keeping itself alive all this time by the vast quantities of nourishment it is continually taking in. At length, when these worms are arrived at their full growth, they spin themselves a webb, under which they change into chrysales, and soon after come out in form of the fly that laid the egg. This is not peculiar to this single species of fly; but many are educated thus in the bodies of caterpillars of several kinds: some of these spin their webs under the skin of the caterpillar, and eat their way through it, when arrived at their perfect state; but others crawl out while yet in their worm state, after having eaten their full time, and bury themselves under ground in order to spin their webs.

The species are these: 1. The red-tailed *Ichneumon*, with long wings spotted with black. 2. The black-tail'd *Ichneumon*, with a long and slender body, variegated with annular marks of red and black. 3. The black *Ichneumon*, with three hairs at its tail; the body of this species is intirely black, without the least variation. 4. The black *Ichneumon*, with a white circle on the legs, and on the antennæ. 5. The *Ichneumon* with a thick breast, and a body beginning by a slender filament, and terminating in a thick tail. 6. The great large winged *Ichneumon*, with a yellow body, and large yellow spots on the wings. 7. The smaller large-wing'd *Ichneumon*, with black wings, and a black body and tail. 8. The red-leg'd *Ichneumon*, with a body red at the beginning, and a white large spot upon the back. 9. The large *Ichneumon*, with a black head, breast, and legs, a red body, and black tail. 10. The flat-body'd *Ichneumon*, with a black back, and greenish white belly. 11. The slender body'd *Ichneumon*, brown on the back, with one yellow transverse line, and yellowish on the belly. 12. The small three-haired *Ichneumon*, with long antennæ.

13. The small black *Ichneumon*, with a white cross upon its back. 14. The reflex horned *Ichneumon*, with its anterior feet clypeated. 15. The black body'd *Ichneumon*, with two broad circles of yellow on the middle of the back. 16. The black body'd *Ichneumon*, with a white tail, and a white triangular spot on the shoulders. 17. The long bodied *Ichneumon*, with a yellow body and black tail: this is an inch and a quarter in length, and is a very beautiful species. 18. The large caterpillar *Ichneumon*, with the anterior half of the body of a bright orange colour, and the other half black. This is produced in the body of another species of caterpillar. 19. The black *Ichneumon*, with orange coloured legs. 20. The small *Ichneumon*, with yellow legs, and a yellow back, and three hairs at the tail. 21. The small *Ichneumon*, with three hairs at its tail, with shining wings. 22. The black *Ichneumon*, with several narrow yellow circles on the hinder part of the body. 23. The black breasted *Ichneumon*, with the anterior part of the body yellow, and the hinder part black. 24. The caterpillar *Ichneumon*, with no hairs at the tail, and with very long horns. 25. The long-bodied caterpillar *Ichneumon*, with only one hair at the tail: these are produced of worms lodged in the bodies of different kinds of caterpillars. 26. The black and yellow *Ichneumon*, with purple wings. 27. The slender bodied *Ichneumon*, with purple wings. 28. The orange-coloured *Ichneumon*. The whole body in this species, is of a reddish yellow, with no spot, or variegation in it. 29. The black bodied *Ichneumon*, with red legs, and shining wings; each marked with one spot. 30. The variegated leg'd *Ichneumon*, with a white circle on each antenna. The legs of this species are partly black, and partly red. 31. The large *Ichneumon*, with a yellow body and black tail: and, 32. The inky wing'd *Ichneumon*. *Ray*'s Hist. of Insects, p. 254, *& seq.*

VESPERTILIO, the *bat.* In the Linnæan system of zoology, this animal makes a distinct genus; but not as a bird, as the vulgar esteem it, but as one of the quadruped class. The characters of the genus are these: That the creature is viviparous, whereas all the birds are oviparous: that it has two paps: its feet have five toes on each; and the four feet are expanded into a sort of wings. Under this class, the author takes in the canis volans, and glis volans; the flying dog and flying dormouse, as they are called by other authors. *Linnæi* System. Nat. p. 37.

Bontius describes a very strange kind of *Vespertilio*, or bat, as he calls it, found in the East-Indies; and Piso, who has thoroughly considered the subject, doubts much, whether it can properly be referred to the bat kind or not. Indeed, it seems more properly to belong to the class of the flying squirrel. *Bontius* calls it the *Verspertilio admirabilis*, and describes it as being of the size of a cat, and of a fleshy body; and says, that it flies by means of membranes annexed to the sides of its body, and to its fore-legs; and that it can expand these to a vast compass. From all this it appears to be of the squirrel kind; but he adds, that they fly in flocks, like our wild geese, which seems very improbable; and it seems rather, that the creature was intended only for long leaps. If Scaliger had known this animal, it would be very natural to believe he meant it under the name of the *felis volans*, or flying cat; which is generally supposed another name only for the common flying squirrel.

VESPERTILIO, in conchyliology, the name of an elegant species of voluta, supposed to have some resemblance to the colour of a bat. See the article VOLUTA.

VESPIVORUS *buteo*, in zoology, a name given by some authors to the bird, called in English, the honey-buzzard, from its feeding its young with the maggot worms out of honey-combs. *Willughby*'s Ornithol. p. 39. See the article APIVORUS *Buteo*.

VESSEL (*Cycl.*)—*Extraordinary* VESSELS, in anatomy. It is not uncommon to meet in the bodies of dissected persons remarkable variations from the common course of nature in the structure of the body; and among these, sometimes duplicates of parts naturally single: thus Kerkring mentions a double *vena cava*, and a treble ductus thoracicus in different bodies, as also four spermatic arteries in one body, with no spermatic veins: there are accounts also of defects of parts usually judged essential; but it is to be observed, that the ends of nature being much more easily answered by the excess, than by the defect of parts, the accidents of excess are greatly more common than those of defect. *Kerkring*'s Spicil. Anat.

Chemical VESSELS. See the Appendix.

VESSIGON, in the manege, a wind-gall, or soft swelling, on the in and outside of a horse's hough, that is, both on the right and left of it.

VETCH, *Vicia*, in botany. See the article VICIA.

Horse-shoe VETCH. See the article FERRUM *equinum.*

Bitter VETCH, in botany. See the article AROBUS.

VETO, in Roman antiquity, was the solemn word used by the tribunes of the people, when they inhibited any decree of the senate, or law proposed to the people, or any act of other magistrates. *Liv.* 6. 37. *Middlet.* of Rom. Sen. p. 160. See the article INTERCESSION.

VETOLA, in zoology, a name used by the Venetians, and from them by many others for a water-bird of the godwit kind,

kind, called by Aldrovand, the *Totano*, and by Gefner, the *Fedoa fecunda*.

It ufually weighs about nine ounces; its beak is fhaped like that of the woodcock, and is red all over, except at the end, where it is blackifh; its neck is grey; its belly and breaft white; its head of a brownifh grey; and its back brown; but its rump has a white ring on it; its tail is compofed of black and white feathers. *Ray's* ornitholog. p. 216.

VETTONICA, in botany, the antient way of fpelling the word *Betonica*, the name of a plant called in Englifh, *Betony*.

It is called *Vettonica* by Pliny, who fays, it obtained that name from a people of Italy fo called, among whofe woods it grew.

We are far from being certain what plant the antients mean when they prefcribe *Betony*, fome having applied the name to the fame plant, which we at this time call by it; others calling the *ferratula* or faw-wort, by this name, and others rofemary.

Diofcorides mentions only one kind of *Betony*, which he calls *ceftra* and *pfuchrotropha* in the Greek, and which his tranflators explain by *Vettonica vel rofmarinus*; and this is countenanced in exprefs words by the author himfelf, in one place, where he fays the plant *ceftra* is called *pfuchrotropha*, from its being produced in damp places; and that the Romans called it *Betonica*, or *rofmarinus*.

This feems abfolutely confounding the two plants *rofemary* and *Betony*.

The *Betony*, faw-wort, and rofemary, of the prefent times, are three very different plants; and we are therefore not to cenfure the antients, if any one of them wants the virtues they afcribed to *Betony*, but to try them all round.

However, if any thing certainly can be judged of the *betonica* of the antients, it is, that it was our *ferratula*. See the article SERRATULA.

VEXILLARII, among the Romans, were veteran foldiers, the fame with thofe the old Romans called *triarii*. There were fix hundred of them in every legion. See the article TRIARII, *Cycl.*

VIATORES, among the Romans, officers whofe bufinefs it was to go into the country, and acquaint the fenators of the extraordinary days on which they were to meet. See Mem. de l'Acad. vol. 1. p. 405.

VIBA, VUBA, or VABA, names by which fome botanical authors call the common fugar-cane. *Pifo*, p. 119. *Marggrave*, p. 82.

VIBEX, (*Cycl.*) a word ufed by fome to exprefs a black mark upon the fkin, from a bruife.

VIBRANT, or VIBRION, in natural hiftory, the name of a clafs of flies, commonly known by the name of the *ichneumons*.

The word is derived from the Latin *vibro*, to fhake or quiver, and is applied to thefe flies, from the continual vibrating motion obferved in their antennæ.

VIBRISSÆ, a word ufed by medical writers to exprefs the hairs in the noftrils.

VIBURNUM, in botany, the name of a genus of trees, the characters of which are thefe: The flower confifts of only one leaf, and is of the rotated kind, and divided into feveral fegments at the edges. The center of this flower is perforated by the pointal of the cup, which finally becomes a roundifh, foft and juicy berry, containing a hard ftriated feed, of a flattifh figure.

There is only one fpecies of this tree, which is the common *Viburnum*. *Tourn.* Inft. p. 607.

VIBURNUM *Galls*, in natural hiftory, the name of a fpecies of galls, or fmall protuberances, frequently found on the leaves of the *Viburnum*. Thefe are of a very fingular nature, and feem to be compofed of a different fubftance from that of the leaf. They appear in form of brown circular fpots, of which there are fometimes forty or more on one leaf. Thefe are about a fifteenth of an inch in diameter, and they rife a little above the furface of the leaf, as well on the under as the upper fide; each of thefe has alfo a fmall prominence in the center, on each fide of the leaf, looking like a nipple ftanding on the breaft.

Thefe are found in great plenty in the months of June, July, and Auguft, and, when opened, each contains one infect, which is a fmall worm of a white colour, with fix legs, and two hooks of a brown colour at the head. The manner of watching the changes of this infect is this: Place feveral of the leaves of this fhrub, with their pedicles, in a veffel of water; fet this upon a fheet of white paper, on a fmooth table, and cover it with a box, the edges of which muft touch the paper every where; by this means the leaves will be kept frefh, fo long as is neceffary for the feeding of the animal in the galls; and this, after its proper changes, efcaping out of the galls, muft be found within the outer box. Mr. Reaumur tried this method with fuccefs, and found that thefe worms became, in fine, a very fmall fpecies of beetle, feveral of which he found crawling upon the paper. They were of a cinnamon colour, and had conic and granulated antennæ of a beautiful figure. *Reaumur's* Hift. Inf. vol. 6. p. 209.

VICARDI, the name of an office in the ifland of Candia. The word is probably a corruption of the Latin *vicarii*. The *Vicardi* is the governor of a village, and is fometimes the parifh-prieft; his office is to levy the public taxes, and to fend offenders to the cadic. This office is always appointed yearly. *Pocock's* Egypt, vol. 2. p. 2. p. 12.

VICARIO *Deliberando occafione cujufdam recognitionis*, &c. An antient writ that lies for a fpiritual perfon imprifoned. Reg. Orig. 147. *Blount*, *Cowel.*

VICES, a term ufed by the dealers in horfes to exprefs certain faulty habits or cuftoms in that creature, which render him troublefome to the rider, and are never to be worn off, but by attention to the regular methods.

The following are the tricks generally underftood as *Vices* by dealers, and their methods of preventing, correcting, and curing them.

1. If a horfe carry his head or neck awry, ftrike him twice or thrice with the fpur on the contrary fide; but if he be very ftiff-necked on the right fide, and very plying or bending on the left, the rider is to hold the right rein fhorter than the other, and give him fudden checks every time he inclines that way, having a fharp wire faftened in the reins, that ftriking in his neck, he may be compelled to hold it ftrait; but in this care muft he always taken to check him upwards, for otherwife he will get a habit of ducking his head, which will prove very troublefome.

2. If a horfe is apt to fhake his head and ears, upon the leaft occafion, or move his ears, when he is going to kick or bite, or caft his rider; the way of curing this, is to ftrike him on the head with a wand, as foon as he fhews the firft attempt to it; and, at the inftant of ftriking him, he is to be checked with the bridle, and be ftruck with the fpur on the contrary fide; this will put him out of his pace, and he is then to be ftopped, that he may have leifure to underftand the rider's meaning. Every time that he ftarts or winches, which are fignals that he is going to bite, or to ftrike with his heels, the fame is to be done, and he will, by degrees, be broke of thefe habits.

3. If a horfe is fubject to ducking down his head frequently, the rider muft, every time he is guilty of it, check him fuddenly with the bridle, and at the fame time ftrike him with the fpurs, in order to make him fenfible of his fault. If he be ftanding, he is thus to be made to bring his head in the right place as he ftands; and when he does fo, he is to be cherifhed, that he may underftand the rider's meaning, which, in time, he will certainly do.

4. If a horfe be fkittifh, and apt to ftart, fo that the rider is never free from danger, while on his back, the caufe of the malady is firft to be carefully enquired into: If it be found to proceed from a weak fight, which reprefents objects to him other than they really are; the method of curing him is, every time he does it, to give him leifure to view the things, and fee what they really are; he muft have time to view them well, and then be rid gently up to them. If, on the contrary, his fkittifhnefs depends on his being naturally fearful, and alarmed at every noife, he is to be cured of it by the inuring him to loud noifes of many kinds, as firing of guns, drums, trumpets, and the like; and he will, in time, come to take delight in what he was before afraid of.

5. If a horfe be reftive, and refufe to go forward, the rider is to pull him backwards, and this will often occafion his going forward; this is ufing his own fault, as a means of reclaiming him. The rider is firft cautioufly to find whether this *Vice* proceeds from real ftubbornnefs, or from faintnefs; if from the latter, there is no remedy but reft; but if actual ftubbornnefs be the fault, the whip and fpur, well employed, and perfifted in, will, at length, be found a certain cure.

6. If a horfe rear up an end; that is, if he rifes fo high before as to endanger his coming over the rider, the horfeman muft give him the bridle, and bear forwards with his whole weight. As he is going down, he fhould have the fpur given him very roundly; but this muft by no means be done as he is rifing, for then it will make him rife higher, and, probably, come over.

7. If a horfe be fubject to lie down in the water, or upon the ground, there is no better remedy than a pair of fharp fpurs refolutely applied. But there is fome caution to be ufed in the applying them, for bad horfemen generally are the occafion of the faults in horfes, by correcting them out of due time. The proper moment of fpurring is juft when he is going to lie down; but when this has diverted him from the thought of it, he is not immediately to be fpurred again. For the doing this frightens the creature, and puts him into confufion to that degree, that he at length becomes reftive, and thus one fault is only changed for another, and that perhaps a worfe.

8. If a horfe be apt to run away, very cautious means muft be ufed to break him of it. The rider muft be gentle, both with a flack curb, and keeping an eafy bridle-hand. He is firft to be walked without ftopping him; but only ftaying him, by degrees, with a fteady, not a violent hand, and always cherifhing him when he obeys: When he is thus made very manageable in his walk, he is to be put to his trot, and finally to his gallop; and from thefe he is to be brought into a walk again, always by degrees, and ftaying him with a fteady hand. By ufing this method from time to time, with judg-

judgment and patience, it is probable he may at length be cured.

9. If a horfe is apt to fly out violently, it is certain, that the more the bridle-rein is pulled, and the more he is hurt by tugging the curb, the fafter he will run: The beft method is therefore, if there be field-room enough, to let him go, as foon as he is going, by flackening the bridle, and giving him the fpur continually and fharply, till he flacken of his own accord. Thus, by degrees, he will find that himfelf is the fufferer, by all his flights, and he will then leave them off, tho' he could be never broke of them any way elfe.

10. Some horfes will not endure the fpurs when they are given them, nor ever go forwards; but faftening themfelves to them, they will ftrike out and go back; and if they are preffed more hard, they will fall to piffing without ever going out of the place. If the horfe who has this *Vice* be a gelding, it will prove very difficult to cure him of it. A ftone-horfe, or a mare are much eafier cured; but even thefe will be trying at it again afterwards; and if ever they get the better of their rider, they will not fail to keep it up in this particular.

Every horfe, of whatever kind, that has this fault of cleaving to the fpurs, as the jockies call it, and not going forwards with them, is to be rejected, in the buying for any gentleman's riding, for it is a fign of a reftive nature, and is a fault generally accompanied with many others.

VICIA, *Vetch*, in botany, the name of a large genus of plants, the characters of which are thefe: The flower is of the papilionaceous kind; and the piftil, which arifes from the cup, finally becomes a pod, furnifhed with roundifh or angular feeds; to this it is to be added, that the leaves ftand in pairs on the rib, and that terminates in a tendril.

The fpecies of *Vetch*, enumerated by Mr. Tournefort are thefe: 1. The common cultivated *Vetch*, with black feeds. 2. The common cultivated *Vetch*, or tare with grey feeds. 3. The cultivated *Tare*. 4. The great wild bufh *Vetch*. 5. The bufh-*Vetch*, with roundifh, but pointed leaves, and with black feeds. 6. The bufh-*Vetch*, with roundifh, but pointed leaves, and with fpotted feeds. 7. The bufh-*Vetch*, with narrower-pointed leaves, and a fmall black feed. 8. The many-flowered *Vetch*. 9. The hoary perennial many-flowered *Vetch*. 10. The great-many-flowered *Vetch*, with variegated blue and white flowers. 11. The hairy perennial many-flowered *Vetch*, with pea-like pods. 12. The white-flowered hairy wild *Vetch*. 13. The great early French hairy wild *Vetch*, with red flowers. 14. The bufh *Vetch*, with a roundifh, fhort, and blunt-pointed leaf. 15. The corn *Vetch*, with numerous hairy pods. 16. The corn *Vetch*, with fingle fmooth pods. 17. The leaft *Vetch*, with numerous fmooth pods. 18. The long-leaved *Vetch*, with longer pods. 19. The narrow-leaved violet purple-flowered *Vetch*, with broad fmooth pods. 20. The many-leaved *Vetch*, with fmooth pods. 21. The *Vetch* that buries many of its pods under the ground. 22. The leaft early French *Vetch*. 23. The procumbent *Vetch*, with broad, not ferrated leaves. 24. The procumbent *Vetch*, with very broad leaves, and with ferrugineous-coloured flowers and fruit. 25. The procumbent *Vetch*, with very broad ferrated leaves. 26. The largeft wild *Vetch*, with the appearance of the wild pea. 27. The wild yellow *Vetch*, with a hairy pod. 28. The perennial late-flowering yellow *Vetch*, with hairy pods. 29. The perennial late-flowering yellow *Vetch*, with fmooth pods. 30. The yellow-flowered *Vetch*, with a brown galea to the flower. *Tourn.* Inft. p. 397.

VICOMAGISTER, among the Romans, an officer whofe bufinefs it was to take care of the ftreets, that nothing might obftruct, or render them anywife incommodious. *Hofm.* Lex. Univ. in voc.

VICTORIATUS, among the Romans, a coin with victory reprefented on one fide, equal in value to half the *denarius*. See the article DENARIUS, *Cycl.*

VICTORIOLA, in botany, a name ufed by fome authors for the hippogloffum, called in Englifh the *Alexandria-laurel, horfe-tongue*, or *double-tongue*. *Ger.* Emac. Ind. 2.

VIDIMARUM, in botany, the name of the tree which bears the febeftens, a medicinal plum, of Afia and Ægypt. Hort. Mal. vol. 4. p. 77.

VIELLE *ridée*, the *wrinkled old Woman's Shell*, a name given by the French authors to a fpecies of *chama* of the mutilated kind, very much refembling the famous *concha veneris*, but longer, and without that peculiarly-fhaped oval aperture to which that fhell owes its name.

It has feveral fpines about the lips, as the *concha veneris* has, but they are fhorter and more obtufe than in that fhell. The whole furface of this fpecies is deeply and irregularly wrinkled. It is of a whitifh colour, variegated with brown.

VIELLEUR, in natural hiftory, the name of a fpecies of fly, common in Surinam, and fome other places. It is moderately large, though lefs fo than the lanthorn-fly, fo common in that place, and has a long head, and fome other particulars, in which it refembles that creature. Mrs. Merian has given a figure of it, and reports it as the opinion of the natives, that it changes at length into a lanthorn-fly. See the article LANTHORN-*Fly*.

VIGOROSO, or VIGOROS AMENTE, in the Italian mufic, is ufed to direct a performer to fing or play with vigour, ftrength, and firmnefs.

VIGESIMA, among the Romans, a tax of the twentieth part of the yearly incomes of all inheritances. It was firft eftablifhed by Auguftus. *Pitifc.* Lex. in voc.

VIGESIMA was likewife a cuftom paid for flaves fold, as alfo for one made free. *Pitifc.* in voc.

VIGESIMARIUS, among the Romans, an officer who had the management of collecting the *vigefima*. See the article VIGESIMA.

VILLANELLA, in the Italian mufic, a fort of air or tune to which the peafants of that country dance. There are fome of thefe *Villanellas* very agreeable, having fomething gay and enlivening in them, well adapted to their defign. The firft couplet is ufually played plain and fimple, afterwards come an infinity of variations, diminutions, &c.

VILLEIN *Fleeces*, in our Statutes, are bad fleeces of wool, fhorn from fcabby fheep. 31 Ed. 3. c. 8. *Blount, Cowel.*

VILLOSE *Stalk*. See the article STALK.

VILTRUM, a word ufed fometimes alone to exprefs a filtre, inftead of the word *filtrum*. But *Viltrum* is more commonly joined with the word *philofophorum*, and then expreffes the common alembic for diftillation.

VIMMALA, in natural hiftory, a name given by the people of the Eaft Indies to a kind of pyrites, of a braffy appearance, and of a cubic figure.

They alfo give it in the fame places to the *pyritæ* in general, when fmall and of a fimple internal ftructure.

VINAGO, in zoology, a name given by fome authors to the wood-pigeon, from the colour of its breaft, fhoulders, and wings, refembling that of red wine. Its more ufual name among authors is *Œnas*. See the article ŒNAS.

VINDICTA, among the Romans, the prætor's rod or fwitch, with which he touched a flave's head when he was affranchifed. *Danet.* in voc.

VINCETOXICUM, in botany, a name ufed by many authors for the afclepias, or fwallow-wort, from its fuppofed virtues as an antedote. See the article ASCLEPIAS.

The people of Stiria and Carinthia are more fubject than any other nation to fcrophulous difeafes; but nature has provided them alfo with a very ready and fafe remedy, which is the *Vincetoxicum*, or fwallow-wort. This grows in vaft abundance all over thefe countries; and the common people know it as a certain cure for this terrible difeafe. It is alfo found of excellent ufe in dropfies; and as it might be cultivated with us, or its roots imported in any quantities, it is wonderful that we do not ufe it.

VINE, (*Cycl.*) *Vitis*, in botany. See the article VITIS.

All the forts of *Vines* are propagated either from layers or cuttings. The former is the method ufually practifed with us, but the latter feems much the better.

In order to propagate them by cuttings; thefe muft be chofen fuch as are ftrong and well-ripened fhoots, of the laft year's growth, and fhould be cut from the old *Vine*, juft below the place where they were produced, taking a knot of the two years wood, which fhould be pruned fmooth. The upper part of the fhoot fhould then be cut off, fo as to leave the cutting about fixteen inches long. Thefe cuttings are to be placed with their lower part in the ground, in a dry place, laying fome litter about their roots to prevent them from drying. In this place they fhould remain till the beginning of April, which is the time to plant them. They are then to be taken up and wiped clean, and if they are very dry, they fhould ftand with their lower parts in water fix or eight hours. Then, having prepared the beds for them, they are to be fet at about fix foot diftance from each other, and making their heads flant a little toward the wall. The cutting is to be fo buried in the ground, that only the uppermoft bud be upon a level with the furface; the earth is then to be well clofed about the plant, and a little mould heaped up over the eye of the bud, to keep it from drying. After this, there is no more trouble neceffary, but to keep the ground clear from weeds, and to nail up the fhoot as it grows, to the wall, rubbing off all the fide-fhoots.

The Michaelmas following, if the cuttings have produced ftrong fhoots, they fhould be pruned down to two eyes. In the fpring following the ground is carefully to be dug up about the fhoots, and the ftalks to be earthed up to the firft eye. During the fummer all the lateral fhoots muft be rubbed off as they appear, and only the two from the two eyes which were left, muft be encouraged; thefe, as they grow, are to be nailed up againft the wall; and in the middle of July thefe fhould be fhortened, by nipping off their tops, and this will greatly ftrengthen the fhoot. At the Michaelmas following thefe fhould be pruned, leaving them each three eyes, if they are ftrong; but if they are weakly, only two. The next fummer there will be two fhoots from each fhoot of the laft years wood; but if there fhould be two from one eye, which is fometimes the cafe, then the weaker is to be rubbed off. At midfummer the ends of the fhoots are to be pinched off as before; all the weak lateral fhoots are to be difplaced, as in the preceeding fummer, and the whole management is to be the fame. This is all the culture neceffary to young *Vines*.

As to the management of grown *Vines*, it is to be obferved that thefe rarely produce any bearing fhoots, from wood that is more than one year old; the great care muft therefore be always to have plenty of this wood in every part of the tree.

The bearing shoots for the following year should be left at the pruning with four eyes each. The under one of these does not bear, and consequently there are only three which do. Many leave more eyes on the shoots, that they may have more fruit, which is the consequence; but then the fruit is much poorer; and this is so well known in the wine countries, that there are laws to direct that no more than such a number of eyes are to be left on each shoot, for the grapes would else be of a poor juice, and destroy the reputation of their wine. Each of the three eyes left, will produce two or three bunches; so that each shoot will give six or nine bunches, which is as much as it can bring to any perfection. These shoots must be laid in at about eighteen inches asunder on the wall; for if they are closer, when the side-shoots are produced, there will be no room to train them in upon the wall; and the largeness of the leaves of the *Vine* requires also that the shoots should be at a proportionable distance.

The best season for pruning *Vines* is the end of September, or beginning of October. The cut is always to be made just above the eye, and sloped backward from it, that if it bleed, the juice may not run upon the bud; and where there is an opportunity of cutting down some young shoots to two eyes, to produce vigorous shoots for the next year's bearing, it should always be done. In May, when the *Vines* are shooting, they should be looked over, and all the shoots from the old wood should be rubbed off, as also the weaker, whenever there are two produced from one eye. During the month of May the branches must be nailed up against the wall as they shoot, and toward the latter end of this month, the ends of the bearing branches should be nipped off, which will greatly strengthen the fruit. Those, however, which are to bear the next year, should not be stopped before the beginning of July.

When the fruit is all gathered, the *Vines* should be pruned, whereby the litter of their leaves is all removed at once, and the fruit will be forwarder for this the succeeding year. *Miller*'s Gardener's Dict.

The *Vine* is one of the trees most liable to be injured by frosts with us; its trunk is often split in frosty weather, and that most frequently when it stands in the warmest aspects. In the year 1683, the great frost split almost all our timber-trees; but this was owing to defects in them, by which the sap was detained in very large quantities in particular places, from their being wind-shaken, coltie, or otherwise distempered; but the *Vines* suffered the same accident, seemingly from another cause.

Those *Vines* were most split this year, which were exposed to a south aspect, and planted against the warmest walls. The sun, their usual friend, now proved their enemy, and daily thawing the sap in the trunk, it was again frozen every night. This often bending and unbending, softening and hardening the vivid spirituous juice of this plant, destroyed it; and the sap, being the same year disordered, and not gradually seasoned, but even stopped before Michaelmas-day, and the fresh sap wholly detained by the succeeding frosts from arising, the frozen and hard earth also denying its juices, even though the vessels of the plant had been in a condition to receive them; the trunks and branches of the *Vines* were filled only with a thin, watery, and mortified sap, and this most of it extravasated by the bursting of the vessels it was frozen in, many of them suffered as much as if cut off from the root. Thus perished the greater part of the *Vines* exposed to the sun's action; while the other, which stood in more shady places, not having their juices thawed and frozen daily, suffered but one change, and often escaped. It was also observed this year, that the red grap-trees escaped in general much better than the white, being hardier than they.

Other wall-trees, containing viscous juices, escaped very well, while the *Vines* thus suffered, even though exposed in the same manner. Among others, the plums, apricots, peaches, and wall-cherries, had very little damage. It is easy to conceive why plants with viscous juices should suffer less by frost, than those with more thin ones; and we see that this is the case between these two sorts of trees, the plums, &c. often exsudating their juices in form of gum-arabic; but the *Vines*, when they throw out any, shew that theirs is as thin as common water. The different kinds of trees have, doubtless, all their different consistences in their juices; and it may have principally been owing to that diversity in others, as well as in the plum and *Vine*, that some escape, while others perish by frosts. Phil. Transf. N°. 165.

VINE *Gallinsect*, an insect of the *gallinsect* class, principally found on the *Vine*, though capable of living on some other trees, and sometimes found on them. It is much of the same shape, figure, and manner of life with the other animals of this class; but differs from them in this; that as they lay their eggs all under their body, and continue absolutely to cover them, till they are hatched; these protrude them from their body, and they are found in prodigious abundance, lodged in a sort of cottony or silky bags all over the stalks and branches of the *Vines*; the dead animal is sometimes found covering them in part; but more frequently they are absolutely naked, and often are so numerous as to appear like thin cobwebs hung one over another all over the *Vine*. See Tab. of Insects, N°. 32.

These eggs might be easily mistaken for those of small spiders; they always hatch well, and come to maturity on the *Vines* they are found on; but if removed to others, they seldom come to any thing, which is very singular, since the *Gallinsects* of almost all other trees may be removed and propagated either on the same or on different trees. These nests of eggs, covered with down, and thus lodged on the *Vine*, are of no certain shape or form; sometimes they are convex and roundish; but that is not always the case, they stick to the fingers on touching, and are pulled away in small irregular threads; if these are pulled away to any considerable distance, the eggs come among them; they are oblong, reddish, and of smooth shining surfaces, and are amassed in vast numbers in the center of each of these little packets.

The insect, as it lays these eggs, directs them under its body toward its head, and thence downward toward the tail again; they are all arranged like the beads of a necklace, and make long chains or strings, thus directed, and running backward and forward with several sinuosities; and the cottony matter in which they are enveloped, is not like that of spiders, produced from certain particular organs appointed for the spinning it, but sweats out, as it were, from every pore of the creature's body; but most of all from its sides; it seems to be produced in extremely small and short filaments; but, being of a viscous nature, will draw out on the touch like glue or warm resin; and long threads of it are originally formed by the course of the chains of eggs before described, which take it up in their course, and form it into numerous threads of their own length, as it goes on.

These *Vine* insects are of the boat-fashioned kind; but, beside these, there are some other species which lodge their eggs in a cottony nest of the same kind. The common thorn affords a shorter and more convex kind that this does; these are a very small species; others are something larger; but the oak affords a sort equal in size, if not exceeding those of the *Vine*; some of these are brown, others bluish, and others reddish; and there are some minute differences in their shape. *Reaumur*, Hist. Inf. Tom. 4. p. 61.

VINE *Grubs*, in natural history, a name given by some authors to the pucerons, or little insects, which are usually of a green colour, and are found often in prodigious numbers, sticking to the leaves of trees and plants, and to their young stalks.

Mr. Reaumur has been very curious in his investigation of the nature of this insect; but its manner of propagating its species was never clearly observed, till Mr. Bonet discovered it.

Reaumur observes, that in every family of pucerons, there are some that have wings, and some that have not; and that, according to the usual course of nature, the winged ones should be males, and the others females; but, on the contrary, that both the winged and the unwinged *Vine-grubs* are females, all being viviparous, and each kind producing a number of living young; so that the males of these pucerons were never discovered, even by that careful observer; nor could he ever find out what it was that impregnated the one and the other kind. He leaves us queries on this subject, whether there is no copulation among them, and whether they are all hermaphrodites, each having in itself the organs of both sexes, as is the case in the river muscles.

Mr. Bonet, in order to inform himself of the process of nature in these creatures, brought up one of them in perfect solitude from its birth; he had an opportunity of observing it in the place where it was kept, and watched it very strictly for many months together. At the end of twelve days this creature, without having had any copulation with a male, began to breed. She produced in the whole ninety-five young ones, all alive, and constantly under the eye of the observer. This experiment was repeated several times with the same success; and, at length, repeated upon the young ones produced in this manner, and they were found to breed at the same period, and in the same manner with their parent, without having had any copulation with a male, as far as to the fourth generation.

A hasty observer would immediately conclude from this, that there was no copulation among the pucerons; but farther enquiry proves, that this is not the case; for the same observer has found a species of them in which there is copulation; so that both the winged and the unwinged kinds are truly females, and the male is a small fly, of a very different shape, as is the case in regard to many other insects. This male is the most salacious creature imaginable, copulating a vast many times successively, with the same, and with different females. As this is the case in regard to one species of this creature, it doubtless is so also in regard to the rest, though that has not yet been observed: And the singularity seems to be this, that after the male has copulated with the female, she not only becomes prolific, but her young ones are born ready impregnated, as far as to the fourth generation; after which, probably, there is a necessity for the copulation with the male again.

There is another very singular observation also in the production of the young pucerons; the females are properly viviparous, and usually bring forth live young; but they sometimes produce only a sort of foetus's, which are laid in long series one beside the other, as the caterpillar-eggs are laid by

the butterfly; and they are left to hatch, as it were afterwards, by the heat of the fun: Philof. Tranf. N°. 469.

VINEGAR (*Cycl.*)—It is plain that the original component matter of *Vinegar* is fugar, which, in the art of acetification, feems wholly converted into a fluid tartar, and if the aqueous liquor be feparated from *Vinegar*, we find the *Vinegar* is thereby made the ftronger, infomuch that if *Vinegar* were to be highly concentrated by congelation, it would become almoft folid, or a kind of actual tartar.

Whence the rule is eafy, that, in order to make an almoft folid *Vinegar*, we fhould endeavour to diffolve tartar in an aqueous liquor, whence to perfect the art of acetification. The diffolving of tartar largely with fugar or treacle, and the ftrongeft *Vinegar*, by repeated imbibitions, that and a proper management is much to be recommended to the perfons concerned in this trade. *Shaw's* Lectures, p. 205.

It is very well known that a very large quantity of water, or mere infipid phlegm, is contained in *Vinegar*, and that what we call *Vinegar*, would be infinitely ftronger, if cleared of that. It is for this reafon, that a great quantity of *Vinegar* will faturate but a very fmall portion of an alkaline falt; and a great deal of this aqueous acid is, for the fame reafon, required to diffolve a fmall portion of metal. A pint of the ftrongeft *Vinegar* will fcarce diffolve more than two drams of iron, and will not faturate more than the fame quantity of pure falt of tartar.

It has been wifhed by many, that fome method could be contrived of concentrating *Vinegar*, fo as to give it more ftrength; this muft depend alone on the extracting the aqueous humidity; and this has been attempted feveral ways. Of all others, however, that fucceeds beft which we find recommended by Stahl, which is by freezing. This method fo far deprives *Vinegar* of its fuperfluous water, and fo far collects its acetous penetrating fharpnefs, as to render it an extremely powerful menftruum, throwing out five or fix parts of phlegm, which fcarce taftes at all four, and having one fixth or one feventh part poffeffed of all the virtues of the whole. Dr. Shaw affures us, that he has repeated this experiment, and found it to anfwer perfectly upon the trial.

This condenfed *Vinegar*, toward the end of the operation, or in the laft congelations, lets fall a white fhining powder, which is a tartar that, though diffolved in great quantity in the whole aqueous fluid, could not be retained in this concentrated one. *Stahl* de Condenfat. Vini.

The thicker *Vinegar* is, the lefs fit it proves for diftillation, as there is always the greater danger of an empyreuma, or burnt fmell, which would fpoil the whole procefs, and as it ufually in this cafe comes over oleaginous. And the pureft white falt of tartar, faturated with this diftilled *Vinegar*, being afterwards ignited, turns black, and yields a fmell extremely like that of crude tartar in the calcination. *Shaw's* Chemical Effays.

On the other hand, the more the *Vinegar* is diluted immediately before diftillation, the lefs danger there is of burning: And if the thick remaining mafs, when the thinner part is diftilled from it, be again diluted with water, it may, by a fecond diftillation, be brought to afford an acetous fubftance; though this latter be by no means comparable to this former volatile part. This Vigani juftly fufpects to be a thing known but to very few. And even when the *Vinegar* it diftilled with the utmoft labour and care, it ftill has this effect in a higher degree, and contains an immenfe quantity of phlegm, in proportion to its acid falt.

In this cafe, the method of condenfation by freezing is of the utmoft fervice; firft of all feparating the more aqueous part, and in the next place, that which is fomewhat acetous, tho' not comparable to what remains behind; fo that, by this means, a moft concentrated and fubtle fpirituous diftilled *Vinegar* may be produced, *viz.* by freezing the whole parcel of diftilled phlegm and diftilled *Vinegar* together, a thing of great moment to the curious in the *chemia fublimior*, and particularly to thofe who underftand Hollandus. And when the *Vinegar* is froze without diftillation, by this means you have a noble rob, or a rich concentrated *Vinegar*, freed from its diftillating aqueous and ufelefs part. *Vigani*, Medull. Chem.

Vinegar, when applied to fores in animal bodies, ftimulates and refifts putrefaction. When weak, it alfo enjoys the virtues of water; when ftrong, approaches in its effects to thofe of falts and acid fpirits. Med. Eff. Ed. vol. 5. art. 24. See the articles SALT and SPIRIT.

Portable VINEGAR, a name given by the chemifts to a fort of *Vinegar*-powder, or *Vinegar* in a dry form. It is a preparation of tartar with *Vinegar*, and is made in this manner: Take white tartar, half a pound; let it be carefully wafhed, then dried and powdered; infufe this powder in the ftrongeft wine-*Vinegar*, then dry it, and infufe it again, repeating this operation ten times. After this the dry powder is to be kept for ufe; at any time a fort of extemporaneous *Vinegar* may be made by diffolving a fmall quantity of this powder in any proper liquor.

Eels in VINEGAR. The common opinion, from the difcovery of eels in *Vinegar*, that its fharpnefs to the tafte was occafioned by thefe animals, occafioned the accurate Lewenhoek to attempt a careful examination of it by the microfcope.

Some of the ftrongeft and fharpeft *Vinegar*, after having been expofed for fome hours to the air, and afterwards examined by the microfcope, entertains the fight with a number of corpufcles, called the falts of *Vinegar*, which are acute at both extremities, and have many of them in the middle an oblong figure of a brownifh colour, and others were altogether clear, pellucid, and bright as cryftal. Others of thefe particles appeared of an oval figure, and fome of the half of fuch a figure, hollowed like a fmall boat, or the half of a nut-fhell. The more perfect figures, pointed at both ends, and pellucid, are fo very minute, that fome thoufands of them are comprehended in a fmall drop.

Thefe feem to be what affect the tongue with the acid fharpnefs, when we tafte of *Vinegar*; and it is very probable, that befide thefe, minute as they are, there are multitudes of others equally pointed, and infinitely fmaller than thefe.

If *Vinegar* be placed in an open glafs, and fuffered to remain fome weeks, the furface of it will be found, on examination with good glaffes, to be full of the fame figures, double-pointed, and very pellucid; and in thefe, very often, there may be cavities plainly difcovered; but examining the liquor a little deeper down, there are found numbers of minute eels; yet thefe, though minute, are prodigioufly larger than the falt particles, and can never be fuppofed to be the occafion of the fharpnefs of *Vinegar* to the tafte, by any who rightly confider, fince it is not all *Vinegar* that contains them; nay, the much greater part of *Vinegar* is wholly without them, and in winter they all die; yet *Vinegar* is not lefs fharp at that feafon, than in the fummer.

If *Vinegar* be impregnated with crabs-eyes, or any other alkaline fubftance, which blunts, and in a great meafure deftroys its acidity, thefe double-pointed figures are no longer found in it, on a microfcopical infpection; but in their places we find others with an oblong quadrangular bafe, from which they fhoot up into pyramids, and appear like polifhed diamonds. Thefe are alfo fo very minute, that fix thoufand of them are computed to be contained in a drop of the liquor, no larger than two corns of barley. And thefe will be ufually found all of the fame fize, or very nearly fo, which is by no means the cafe with the other falts of *Vinegar* in its natural ftate.

Mr. Mentzelius was fo lucky as to fee thefe undergo their laft metamorphofis, and change into fmall flies: And though this is a fingle inftance, in regard to the microfcopical world of animalcules, yet it is highly probable that the whole race of thofe, whofe appearance in medicated fluids we have been fo long puzzled to account for, may, like thefe, be the worm ftate of fome winged aerial infect, and have owed their origin, where we fee them, to the eggs of parent flies, too fmall for our fight. *Reaum.* Hift. Inf. vol. 4. p. 404.

VINNET, in our ftatutes, is ufed for a flower or border, which printers ufe to ornament printed leaves of books. Stat. 14 Car. 2. c. 33. *Blount.*

VINOUS (*Cycl.*)—VINOUS *Liquors.* All forts of *vinous* and fermented liquors, both before and after the fermentation, confift not of fimilar, but heterogeneous parts, which are joined together in one certain and determinate order; thus the action of fermentation being a feparation and deftruction of the former connection of the fubject, and tranfpofing its parts anew, there muft of neceffity have been a kind of firm or durable texture in the fubject fo disjoined, feparated, and new-ranged.

For example: Grapes being laid upon dry ftraw, in a cold place, will, for fome time after they are feparated from the vine, preferve that texture, which gives them their faline, unctuous, and flimy fweetnefs; which the juice alfo retains after preffing, and becomes a clear and tranfparent muft, without feparating itfelf into parts, but continuing regularly and uniformly mixed, fo as to preferve the different matters it confifts of, intimately connected among themfelves. In this firmly connected ftate they may be kept many months, if a cafk be filled with this juice, and fet in a cool place, as we evidently fee in ftum. *Shaw's* Effay on concentrating Wines.

Wine, in the precife chemical or philofophical notion of it, is a faline clammy oleaginous matter, diluted with a large proportion of water, whereby 'tis expanded, or fet at a diftance from itfelf, while the faline parts are faturated with, and interfperfed among the fubtile earthy ones that make the flimynefs; thus they together imbibe, detain, and hold the groffer parts, befide which there are other oily parts vaftly more fubtile, which, by means of the highly attenuated faline portion adhering clofely to them, remain as much connected with the water as the reft; and thefe are what we call the fpirituous parts; but the connection of them all together is fo ftrong and durable, that they move for a long time as one body, without feparating, if carefully preferved. An acquaintance with the true nature, hiftory, and effects of *vinous* fermentation, will fully explain and juftify thefe pofitions.

If the fpirituous part be once feparated and drawn away from the wine by diftillation, though it were immediately to be returned back to the remaining mafs from whence it came, and ever fo well fhook again with it, the whole by no means retains its former tafte, odour, and durability, but turns to a confufed turbid mixture, of a different and naufeous tafte, and a difagreeable fmell; and, on the whole, approaches nearly to a

a ſtate of vapidity. The only objection to this general rule, is, that if a new fermentation, or even but a fret be raiſed, when the ſpirit is newly joined to the remainder in the ſtill, the ſpirit may be thus re-inſtated, and the wine rendered perfect. The proceſs is different and uncertain; but a nice management, and a proper intermedium, will bring it about.

If an inflammable ſpirit diſtilled from the ſame, or any other *Wine*, be put to a parcel of *Wine* which is too ſaline, or not ſufficiently ſpirituous, the bare addition, or tumultuous admixture thereof, very far from giving the fine and intimate ſoftneſs of a good *Wine*, will rather manifeſt its own burning acrimony and nidorous flavour to the ſmell and taſte, and will add a nauſeous bitterneſs to the former tartneſs or acidity. This is an obſervation of Stahl's, and is allowed by Dr. Shaw to be true in general; but he obſerves, that, under a nice and proper management, a fine and taſteleſs ſpirit may be prepared and introduced into *Wines*, and will, after a time, become intimately mixed with their other part, and remain abſolutely undiſcoverable to the taſte or ſmell, unleſs by the excellency and the ſtrength it gives. *Stahl's* Schediaſma de concentrat. Vini. See the article WINES, SPIRIT, &c.

VINUM *Aloeticum Alkalinum*, a form of medicine in the late London Diſpenſatory, intended to ſtand in the place of Helmont's elixir proprietatis: It is prepared in this manner: Take of bay fixed alkaline ſalt eight ounces, aloes, myrrh, and ſaffron, of each an ounce, purified ſal armoniac ſix drams, white wine a quart; infuſe them together without heat for a week, or longer, and then filtre the wine through paper for uſe. *Pemberton's* London Diſpen. p. 262.

VINUM *chalybeatum*, *Chalybeate Wine*, is thus prepared: Take filings of iron four ounces, cinnamon and mace, of each half an ounce, of Rheniſh *Wine*, two quarts; infuſe a month without heat, often ſhaking the veſſel; then filtre it off for uſe. This is the preſcription of the new London Diſpenſatory, and is vaſtly preferable to that of the former, where only ſaffron was ordered.

This *Wine* is an excellent ſtomachic and aperient; it may be drank a moderate glaſs once or twice a day, or mixed in apozems of the aperient vegetables.

VINUM *Eſſatum*, in chymiſtry, a term uſed by Paracelſus, and ſome others, to expreſs *Wine* concentrated by freezing, after a long and low heat; the method of making it was this: They ſet the *Wine* in horſe-dung three months in a glaſs, hermetically ſealed, and then expoſed it to the froſty air for a month, after which they threw away the ice, and ſaved the unfrozen liquor.

This was their *Vinum Eſſatum*, called alſo eſſence of *Wine*; and ſpirit of *Wine*, and it is in this ſenſe, that Paracelſus ſays, ſpirit of *Wine* is a not-inflammable liquor, a paſſage that very few have underſtood.

Moſt of the antient chemical philoſophers profeſs, that they uſed ſpirit of *Wine* for the diſſolving of gold. We know very well, that what we call ſpirit of *Wine* has no ſuch power; and if we may judge from Rolfink, the emperor Rudolphus employed the *Vinum Eſſatum*, or concentrated *Wine* of Paracelſus, for that purpoſe. *Vigain*, in his *Medulla Chemiæ*, has ſaid a great deal of the virtues of the ſpirit of *Wine*, ſome of which deſerve to be carefully enquired into; the others are evidently idle and imaginary. What Paracelſus delivers on the ſame ſubject, deſerves alſo to be conſidered. *Vigain* Medul. Chem. *Paracelſ.* de Archidoxis.

Stahl, who has written a great deal on the concentration of *Wine* by freezing, concludes his eſſay, by telling us, that he who has this ſecret, by means of a little dry powdry body of turning water into wine, will not perhaps eaſily divulge the capital uſe he may make of ſuch a ſecret.

Dr. Shaw obſerves, that the author of this treatiſe intimates ſomewhat conciſely, but candidly and philoſophically enough, the poſſibility of doing wonders with a thing that is not difficult to be had with us: the myſtery lies in the words, little, dry, and powdery; and Dr. Shaw, tho' he does not perfectly explain himſelf upon the ſubject, ſays, that the body is common, and that England abounds with it; that it is totally and tranſparently ſoluble in water, fermentable, perfectly white, and ſweet as ſugar; the other goes not ſo far as this, nor is it certain that this is his meaning; but if not, it is at leaſt a very remarkable fact, and comes atteſted by a very good hand. Whatever may be the uſes of concentrated *Wine* in chemiſtry, it is plain, that it may be of the greateſt ſervice in the common affairs of life, as it may be eaſy to have it prepared in ſufficient qantities in the *Wine* countries, and imported hither, where a very ſmall portion of it will render the loweſt and worſt of our *Wines* very rich. *Shaw's* Chem. Eſſay.

VINUM *extemporaneum*, a name given by Dr. Shaw and others, to a ſort of extemporaneous vinous liquor, made without fermentation, from the melaſſes ſpirit, lemons, water, and ſugar, in the following manner: Some good ſound lemons are to be cut into ſlices, rind and all, and put into a quantity of pure and fine melaſſes ſpirit; when they have ſtood in infuſion three or four days, the liquor is to be ſtrained clear off, and filter'd; and having before prepared a very thin ſyrup of the fineſt ſugar diſſolved in ſpring-water; the two liquors are to be mixed together. The proportions of this mixture can only be hit by repeated trials, but when once found, it will be eaſy to continue them; and a vinous liquor will thus be prepared not inferior to many foreign wines.

VINI *Oleum*, *oil of wine*, a very precious liquid, kept as a ſecret in the hands of ſome dealers in ſpirits, and uſed to give the brandy flavour to ſpirits of leſs price. It is certain, that all the ſpirits we uſe take their flavour from the eſſential oil of the ſubſtance they are made from, that of malt is very nauſeous and offenſive, and renders the ſpirit horribly diſagreeable, if not carefully kept back in the diſtillation of it; that of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy: this therefore is to be carefully brought over among the ſpirit in diſtillation.

This is that *oil of Wine* ſo much celebrated among our diſtillers, and is for their uſe made ſeparate, and is of ſuch effect, that half an ounce of it will determine a pure and clear malt ſpirit to be French brandy, ſo as to ſtand the teſt of the niceſt palate; and all the trials that can be invented, provided the oil and the ſpirit have both been carefully made.

The manner of making the oil is this: They take ſome cakes of dry wine lees, ſuch as are uſed by our hatters, and diſſolving them in ſix or eight times their weight of water, they diſtil the liquor with a ſlow fire, and ſeparate the oil by the ſeparating pot, reſerving for this nice uſe only that which comes over firſt, the oil that follows being coarſer, and more reſinous. To render this buſineſs perfectly ſucceſsful, there muſt be ſeveral things obſerved: 1. The lee muſt be of the right kind, that is, of the ſame nature with the French brandy propoſed to be imitated. 2. The malt ſpirit muſt be extremely pure. 3. The doſe of the oil muſt be very well proportioned: and, 4. The whole muſt be artificially united into one ſimple and homogene liquor. Theſe cautions all regard only the taſte, and beſide theſe, in order to come up to a nice counterfeit, ſeveral other particulars muſt be attended to; ſuch as the colour, proof, tenacity, ſoftneſs, and the like; ſo that, in ſhort, the operation has too much nicety in it to be hit of by every ordinary dealer. When this fine *Oil of wine* is procured, it may be mixed into a quinteſſence, with pure diſtilled alcohol, or the totally inflammable ſpirit of wine, to prevent its growing diſtaſteful, rancid, or reſinous; and thus it may be long preſerved in full poſſeſſion of its flavour and virtues.

The ſtill bottoms, of remaining matter after the diſtillation of this oil, will yield many productions to advantage, particularly tartar, and ſalt of tartar, as alſo an empyreumatic oil, and a volatile ſalt, like that of animals. Some kinds of lees afford all theſe in much greater quantity than others; the lees of canary and mountain wines yield very little of them, and indeed, ſcare any tartar, or fixed ſalt at all; but the white French lees of thoſe thin wines, that afford the ordinary brandies, yield them all very copiouſly, inſomuch, that ſometimes a ſingle hogſhead of dry and cloſe-preſſed lees will afford by this proceſs, three gallons of brandy, forty pounds of clean tartar, a large proportion of empyreumatic oil, and volatile ſalt, beſide full four pounds of good ſalt of tartar. It is not to be expected, however, that every parcel of this lee ſhould yield fully in this proportion. *Shaw's* Eſſay on Diſtillery.

Chium VINUM. See the article CHIUM *Vinum*.

VIOLA, the *Violet*, in botany, the name of a genus of plants; the characters of which are theſe: The flower is of the polypetalous, anomalous kind, much reſembling the papilionaceous ones. The piſtil ariſes from the cup, and finally becomes a ſeed veſſel, uſually of a trigonal form, which opens in three places when ripe, and contains roundiſh ſeeds.

The ſpecies of *Violet*, enumerated by Mr. *Tournefort*, are theſe: 1, The common purple ſweet-ſcented *Violet*. 2. The ſweet-ſcented garden purple *Violet*, with large leaves. 3. The common wild ſcentleſs *Violet*, with larger and rounder leaves. 4. The common wild ſcentleſs *Violet*, with longer, narrower, and more pointed leaves. 5. The common white *Violet*. 6. The blue flowered *Violet*, with ſmaller flowers, and ſmaller leaves. 7. The double purple *Violet*. 8. The double red *Violet*. 9. The double white *Violet*. 10. The double variegated red and white *Violet*. 11. The greyiſh flowered double *Violet*. 12. The double *Violet*, with very large flowers. 13. The double *Violet*, with very deep purple ſmall flowers. 14. The round-leaved marſh *Violet*. 15. The mountain *Violet*, with leaves divided into many ſegments. 16. The purple alpine *Violet*, with very ſmall leaves. 17. The round-leaved yellow flowered alpine violet. 18. The leſſer round-leaved yellow flowered alpine *Violet*. 19. The dwarf narrow-leaved mountain *Violet*, with ſnow-white ſcentleſs flowers. 20. The purple-tree *Violet*. 21. The tree *Violet*, with blue and white flowers. 22. The yellow-flowered tree *Violet*. 23. The ſweet-ſcented three-coloured mountain *Violet*, or heart's-eaſe. 24. The great flowered yellow mountain *Violet*. 25. The great flowered white mountain *Violet*. 26. The yellow mountain *Violet*, with roundiſh crenated leaves. 27. The blue three coloured mountain *Violet*, with roundiſh crenated leaves. 28. The great flowered blue mountain *Violet*. 29. The yellow mountain *Violet*, with leaves not crenated. 30. The mountain three coloured *Violet*, or panſie, with variegated flowers. 31. The common creeping garden panſie. 32. The creeping garden panſie, with yellow and white flowers. 33. The creeping garden panſie, with white and blue flowers. 34. The

The creeping garden panſie, with purple and yellow flowers. 35. The creeping garden panſie, with plain white flowers. 36. The creeping garden panſie, with *violaceous* velvety flowers, of a deep purple and gold yellow. 37. The creeping garden panſie, with a large blackiſh purple flower. 38. The creeping garden panſie, with a pale velvety flower. 39. The creeping garden panſie, with a gold, yellow, and ſtraw-coloured velvety flower. 40. The two coloured, or white and yellow field *Violet*. 41. The two coloured field *Violet*, with blue and yellow flowers. 42. The two coloured field *Violet*, with blue and white flowers. 43. The field *Violet*, with wholly yellow flowers. 44. The field *Violet*, with wholly white flowers. 45. The long leaved ſhrubby Spaniſh *Violet*. 46. The American *Violet*, with paſſion-flower leaves. 47. The Teucrium leav'd Pyrenean *Violet*, with a long tail to the flower. 48. The rock *Violet*, with a thick, crenated, leaf, like that of baſil, and a large ſcentleſs flower, of a blue colour with white ſtreaks. 49. The purple ſcentleſs *Violet* without a ſtalk, and with leaves like the panſie, but ſcarce at all ferrated. 50. The ſmall hairy-branched erect two coloured *Violet*. 51. The ſmalleſt alpine *Violet*, with leaves like *nummularia*. 52. The great hairy cucumber leav'd Virginian *Violet*, with blue flowers. 53. The great hairy cucumber leaved Virginian *Violet*, with yellow flowers. *Tourn.* Inſt. p. 420.

Violet flowers, freſh gathered, are emollient, and gently purgative. They are greatly recommended by authors in fevers, head-achs, pleuriſies, and peripneumonies. A ſyrup of them made in a ſtrong infuſion in water, is the only preparation kept in the ſhops: it is given to children as a gentle evacuant, and ſerves as a teſt to diſtinguiſh acids from alkali's, the former turning it immediately red, and the latter green.

VIOLA, in ichthyography, a name by which ſome authors have called the ſmelt, from its ſweet ſmell, which has been ſuppoſed to reſemble that of the *Violets*. *Willughby*'s Hiſt. Piſc. p. 202. See the article EPERLANUS.

VIOLA *ſerotina*, the *late Violet*, a name given by the antiens to a garden-flower, not properly of the *Violet* kind, but to which we, as well as they, have connected the name *Violet*, though with a diſtinctive epithet, we call it *Viola matronalis*, or dames *Violet*.

Pliny is very expreſs in this diſtinction, but is not ſufficiently attended to in it; and by this means is miſunderſtood in ſome other parts of his works, where he alludes to this flower in his deſcription of the colour called by the Romans *conchylius*, or *conchyliaceus color*; he ſays, that the deepeſt degree of it was that of the flower of the *Viola ſerotina*. The commentators on his works have generally explained this into his ſaying, That the deepeſt colour of this name was a blue purple, like that of the *Violet*; but he only means that it is of a deeper red than the colour of the mallow flower, and with a proportionate mixture of purple, as there is in that flower. See the article CONCHYLIACEUS *color*.

VIOLARIS *Lapis*, in natural hiſtory, a foſſile body, called by the Germans *Violſtein*, and by many authors, *Lapis odore Violarum*, from its having a ſweet ſmell when freſh broken, which has been ſuppoſed to reſemble that of the *Violet*.

The Germans have many ſtones, which have more or leſs of a ſweet ſmell when freſh broken, as they have many which ſtink very ſtrangely; the latter of theſe they call all by the common name of *ſwine-ſtone*, and the former, all by that of *Violet ſtone*. The ſubſtance, however, which poſſeſſes this quality in the higheſt degree of all others, and is therefore moſt proper to be called diſtinctly by this name, is a ſpecies of talc, of the genus of the bractearia, called by Dr. Hill *brактearium niveum lucidiſſimum bracteis undulatis*, or the ſnow-white ſhining bractearium, with undulated ſcales. This is found in maſſes of an extremely rude and irregular ſtructure, but very compact and firm, uſually of a roundiſh, or oblong figure: theſe are of various ſizes, from an inch or two, to a foot in diameter, and are compoſed of almoſt an infinite number of thin extremely beautiful and ſnow-white plates, which are all broad, thin, and flaky, and of various ſizes, and perfectly irregular in ſhape and figure, and are naturally waved, bent, and curled: its ſmell, when broken, is not like that of any of the known perfumes, but is a ſort of mixed one, reſembling that of roſes and *Violets* together: it is very heavy, and will neither give fire with ſteel, nor ferment with acid menſtruums. It is common on the ſhores of rivers in Italy, and in the mountains in Germany. *Hill*'s Hiſt. of Foſſ. p. 83.

VIOLET, *Viola*, in botany. See the article VIOLA.

VIOLONCELLO. See the article VIOLIN, *Cycl.*

VIOLONE. See the article VIOLIN, *Cycl.*

VIPER, *Vipera*, (*Cycl.*) a poiſonous ſpecies of ſerpent, well known in moſt parts of the world.

Its ſize is uſually two foot and a half in length; its upper part is of a duſky colour, with an admixture of a reddiſh tawney; and in the females with a great deal of whitiſhneſs. Along the middle of the back there runs a broad dentated black line, or a long ſeries of conjunct rhomboidal ſpots, reaching from the head to the tail. A little below this, there is on each ſide a ſeries of ſmall black ſpots; and in the lower part of each ſide there runs a continued line, made by a ſeries of white ſpots, which are very ſmall; then another of larger black ones, and next to this another of ſmall white ones; again, the belly is covered with long black ſcales placed tranſverſely.

This ſeems the general diſpoſition of the colours of the *Viper*, but it is by no means fixed and unalterable; for there are *Vipers* whoſe back is wholly black. The belly however ſeems to be black in all, and the tail does not run to more than a fifth part of the length of the body beyond the anus, and is terminated in a very ſharp point. Wormius ſays, the *Viper* feeds on herbs; but this aſſuredly is not its only diet, ſince there are frequently found in its ſtomach, mice, beetles, ſmall birds, and the like; many of which are often found whole: And it is ſurpriſing to conceive how they were ſwallowed, ſince they are often three times as thick as the whole neck of the ſerpent.

The canine teeth of the *Viper* are only two, and thoſe hollow from the apex to the root; and theſe are not poiſonous in themſelves, but ſerve to make the wound by means of which the poiſon they contain is mingled with the blood. This poiſon ſeems to be a matter ſecreted like ſaliva, by peculiar glands placed in the bags at the roots of theſe dog-teeth. *Ray*'s Syn. Quad. & Serp. p. 285.

By Mr. Boyle's experiments made upon *Vipers in vacuo*, it appeared, that on the withdrawing the air from the veſſel where the *Viper* was put, ſhe began to ſwell, and after ſome time ſhe opened her mouth very wide, and frequently; but on continuing two hours and a half in the receiver, ſhe did not appear to be quite dead. The gaping of the jaws was attended with a loſs of the ſwelling, obſerved at firſt in her whole body; but after every time cloſing them ſhe ſwelled again, and thus became lank and plump reciprocally many times in an hour. During the firſt moments this creature crawled about, as if in ſearch of air, and afterwards foamed at the mouth.

The neck and body continued ſwelled longer, in a ſecond experiment with another *Viper*, and a bliſter appeared on the back. This creature lived an hour and a half. The mouth remained vaſtly diſtended after death, and the internal parts of it were much diſtorted, and thruſt forwards. After the admitting the air the mouth cloſed, and opened again after a time; and in fine, on pinching the tail there was ſome motion perceived in the body, that ſeemed to argue life. The common ſnake bears the exhauſted receiver better than the *Viper*, and after many hours remaining in it, and ſeeming dead, will give ſigns of life on being warmed by bringing the glaſs to the fire; but a longer continuance in the rarified air abſolutely kills it, as it does all other creatures. Phil. Tranſ. N°. 62.

The ſtory of the rattleſnake's charming its prey has been laughed at by many, and by others the effects of the animal's fear have been ſuppoſed the reſult of a previous bite; but we have a great deal of reaſon to believe, that this ſort of faſcination is juſt what it is related to be, from an experiment mentioned in the Philoſophical Tranſactions, of a like thing in regard to a *Viper*. It is well known, that no *Viper* will feed while in confinement, except a female which is with young, but that ſuch a one will. A *Viper*-catcher, who had more than ſixty living *Vipers* in a cheſt, put a living mouſe in among them; there happened to be one female big with young among theſe, none of the others at all regarded the mouſe, but ſhe raiſed up her head a little, and looked furiouſly at it. The mouſe was terrified, and ſtood ſtill for a conſiderable time, though the *Viper* continued rolled up in a ſpiral, only raiſing up its head and looking at it, and vibrating its tongue; the mouſe at length recovered of its fright, and began to move, but without running away, only walking in a terrified manner round and round the *Viper*, and often ſqueaking; at length ſhe came before the head of the creature, which was ſtill raiſed, and the mouth open. The mouſe, after ſome time, went up to the creature, and crept into its mouth, where ſhe was gradually ſwallowed without the *Viper*'s altering its poſture.

The poiſon of *Vipers* is neither in their teeth, their tail, nor their gall, but in two veſicles or bladders which cover their teeth, and which upon compreſſion when the *Vipers* bite, emit a certain yellowiſh liquor, that runs along the teeth and infects the wound.

The poiſon of the *Viper* is only noxious when immediately conveyed into the blood. Nor is it mortal to eat the fleſh of creatures killed by *Vipers*, or to drink the wine in which they have been drowned, or to ſuck the parts they have wounded. On the contrary, Signior Redi ſays, ſucking the wound is a ſovereign remedy againſt the bite of *Vipers*. This author denies, what had been affirmed by Ariſtotle and Galen, that the ſpittle of a faſting perſon kills *Vipers*. Phil. Tranſ. N°. 9. p. 160.

Vipers are viviparous. Phil. Tranſ. N°. 84. p. 138.

The bite of the *Viper* having been ſuppoſed certainly curable by oil of olives alone, and a *Viper*-catcher in England having ſuffered himſelf to be bitten by one of theſe creatures, and having recovered after many dangerous ſymptoms; and the cure being attributed to the oil alone, though other medicines were given him internally; Meſſieurs Geoffroy and Hunauld of the Royal Academy of Sciences at Paris, made a number

of experiments; by which it appeared that this oil was not the great remedy that was pretended. (See the article OIL *of Olives*.) And added to their accounts, some others of persons bitten, in which all the dreadful consequences of that poison are shewn, and the remedies by which they were cured are mentioned. Philos. Trans. N°. 443, 444, 445.

Their first instance is in the case of Mr. Piron, who was bitten at the end of the fore-finger by an enraged *Viper*; there immediately issued a drop of blood from the wound; and the first application made to it was the covering up the whole finger with a quantity of Venice-treacle; the finger, however, swelled violently, and was scarified in several places, and the patient was made to eat the body of the *Viper* boiled, and drank after it a glass of wine with some Venice-treacle, and with a few drops of the volatile spirit of *Vipers*; and the finger was wrapped round with compresses and bandages, wetted in aqua vitæ. Soon after this the patient began to have inclinations to vomit, he vomited very plentifully, the swelling increased, and his arm, which was now very much distended, was scarified in twenty places, and compresses of linnen dipped in aqua vitæ laid on the wounds; he afterwards took volatile salt of *Vipers* in repeated doses, had more scarifications made on his arm, and he drank in the space of an afternoon and evening a quart of strong wine. He slept very sound after this, and the symptoms all disappeared, he was almost recovered by six o'clock the next morning, only the scarifications took two months to heal, and after that time he enjoyed a perfect state of health.

A second instance, is that of a young lad of a robust constitution bitten by a *Viper*, enraged and kept for some time in a very hot place near the fire; he felt a pain like that of oil of vitriol dropped on a wound, but without delay he cut off the head of the *Viper*, bruised it, and applied it to the wound, and tied the finger on which he was bitten very tight round with a binder: He after this had some scarifications made, and rubbed into them a quantity of the fat of the *Viper*; he killed four *Vipers*, and used all their fat, and took three drams of Venice-treacle in some wine. His whole arm swelled, he perceived a violent heat over his whole body, and the other hand was so swelled at length that he could scarce shut it: On this he took a large dose of Venice-treacle, camphor, volatile salt of *Vipers*, of amber and of sal-armoniac, and a dram of volatile spirit of sal-armoniac, and sal volatile oleosum; this he repeated at some distance of time, he was blooded in the opposite arm, the patient vomited violently, and an incision being made all along the finger, there followed no blood. The hand, arm, and breast were embrocated with a mixture of spirit of lavender, camphor, Venice-treacle, and the fat of *Vipers*. After having vomited plentifully, and been embrocated with this warm mixture, he found himself much easier, at eight o'clock at night he took another dose of his volatile medicines, and slept till four in the morning, he then took a large glass of wine and slept till six, and at seven eat a part of a chicken with a good appetite. The surgeons would have made more scarifications on the arm, but he would not suffer it; and three days afterwards an erisipelas appeared, to which he applied a mixture of aqua vitæ and ointment of marshmallows, and finally was perfectly recovered.

These are two instances in which the symptoms of the bite appeared in much the same manner with those of the man who suffered himself to be bitten in England, in order to be cured by the oil. The sleep came on in all in the same circumstances, and they were all cured, as well he who used no unctuous application at all, as he who used the fat of the *Vipers*, or the Englishman who depended upon the oil. The internal medicines given to them all were of much the same kind; and all that can be concluded from the whole, is, that either these bites would not have proved mortal in themselves, or that the cordial medicines, which they took internally were the remedies that prevented the mischief that would have ensued; and these seem to have acted not as specifics against the bite of this animal, but merely as medicines that would stop the spreading of a gangrene; the unprevented increase of which is the thing that proves fatal from this creature's bite.

The dissections of the animals which had died by the bite of the *Viper*, whether they had or had not been rubbed with oil, afforded all the same appearances. The limb which had received the wound was in all swelled and livid, and these symptoms usually were carried along the thigh to the belly, and sometimes up to the breast. Incisions made along these parts always discovered the cellules of the membrana adiposa full of a bloody-coloured water, and the membrane itself was swelled, blackish, and gangrened. And this appeared always more plainly in the belly, than in any other part; the membrana adiposa in all other parts of the body was in its natural state. The injured parts often had a cadaverous smell; the muscles of the wounded limb were also found of a brownish colour, and their fibres had lost their consistence, and seemed ready to give way to the approaching gangrene. Nor is this effect confined to the external parts alone; a goose that had been bitten had three gangrenous spots on its heart, and all the indications of a beginning gangrene in other parts of it; the concave side of the liver was also gangrened, and had wholy lost its consistence; and the lungs of a fowl that had been bitten on the wing, were found in part gangrened. The effects however were different in degree, from the bites of the several *Vipers*; and there seems no reason to doubt, but that the bites of different animals, though of the same species, under different circumstances, either in regard to the creature wounding, or the creature wounded, may be followed with very different consequences; so that remedies are not to be depended on from their success in one or two trials. Mem. Acad. Scienc. Par. 1737.

VIPERA, *Viper*, in zoology. See the article VIPER.

VIPERA *Pileata*, or *Vittata*, in zoology, a name by which some authors have called a remarkable species of Indian serpent, more usually known by the name of *Cobra de Capella*. See the article COBRA *de Capella*.

VIPERARIA, in botany, a name given by some authors to the *Scorzonera*, or vipers-grass. *Dale's* Pharm. p. 83.

VIRGA (*Cycl.*)—VIRGA *Aurea*, *golden Rod*, in botany, the name of a genus of plants; the characters of which are these. The flower is of the radiated kind; its disk is composed of floscules, and its outer circle of semi-floscules. These all are placed upon the embryo fruits, and are contained in a common scaly cup: These embryos finally ripen into seeds, winged with down. To this it is also to be added, that the flowers usually stand in long series towards the tops of the stalks.

The species of *Golden-rod*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved *Golden-rod*, with serrated leaves, called the saracens consound. 2. The broad-leaved *Golden-rod*, with serrated leaves, variegated with white. 3. The common broad-leaved *Golden-rod*. 4. The white-flowered *Golden-rod*, with narrower and less serrated leaves. 5. The mountain *Golden-rod*, with broad smooth leaves. 6. The mountain *Golden-rod*, with broad hairy leaves. 7. The alpine *Golden-rod*, with rigid bay-like leaves. 8. The alpine *Golden-rod*, with long soft and sharp-pointed leaves. 9. The narrow-leaved Canada *Golden-rod*, with a specious panicle. 10. The narrow-leaved hairy Canada *Golden-rod*, with a less specious panicle. 11. The sea lavender-leaved *Golden-rod*, with the flowers all placed on one side the stalks. 12. The large flowered dwarf *Golden-rod*. 13. The annual white-flowered toad-flax-leaved acrid *Golden-rod*, called acrid annual fleabane. 14. The great *Golden-rod*, with viscous and strong-scented leaves. 15. The great *Golden-rod*, with viscous and strong-scented leaves, and with excrescences like galls. 16. The lesser *Golden-rod*, with viscid and strong-scented leaves. 17. The shrubby Portugal *Golden-rod*, with long, narrow, and viscous leaves. 18. The pale purple-flowered *Golden-rod*, with broad auriculated leaves. 19. The purple-flowered *Golden-rod*, with broad and not auriculated leaves. 20. The broad-leaved *Virga-aurea*, with deep violet-coloured flowers. 21. The broad and undulated leaved *Golden-rod*, with pale purple flowers. 22. The Tripolium-flowered *Golden-rod*. 23. The Canada *Golden-rod*, with smooth, roundish, and serrated leaves. 24. The Canada *Golden-rod*, with extremely broad smooth leaves. 25. The tall Canada *Golden-rod*, with leaves hoary underneath. 26. The New-England *Golden-rod*, with broad rigid leaves. 27. The dwarf Canada *Golden-rod*, with toad-flax leaves. 28. The dwarf Canada *Golden-rod*, with the leaves of the smaller willows. 29. The great flowered American *Golden-rod*, with asphodel roots. *Tourn.* Inst. p. 483.

The common *Golden-rod* is an astringent, and its root is given in powder with great success in diarrhœas, dysenteries, and in hæmorrhages of all kinds; particularly in spittings of blood.

VIRGA *Pastoris*, in botany, a name given by some authors to Dipsacus. Vid. *Lemery* & *Miller* in voc *Dipsacus*; also *Tournef.* Inst. Bot. p. 466.

Where the name *Virga pastoris* occurs in the translation of the Arabian writers, it is not to be supposed to mean the plant we call *Virga pastoris*.

It is indeed the literal translation of the hassalelrheir of Serapion and Avisenna; but they called the common horsetail by this name, when they applied the adjective female to it; and when they added male, they meant by it the common knot-grass.

Both these plants possessed the common virtues of astringents and agglutinants, and were for that reason placed together by the old Greek writers, and were both called *Polygonum* by them, having both an equal title to that name, as it expresses no other than a plant that has many joints; and they distinguished the knot-grass by the name of the male *Polygonum*, and the horse-tail by the name of the female; as the Arabians did by the names male and female *Virga pastoris*.

VIRGA *Sanguinea*, in botany, a name given by Mathiolus, and some other authors, to the cornus fœmina, or dogberry-bush, common in our hedges. *Ger.* Emac. Ind. 2.

VIRGÆ *Lateralis Minimus*, in anatomy, a name given by some writers to a muscle, called by others *levator ani parvus*, and by some *transversus ani*. It is called by Albinus the *transversus perinæi*, and by some *transversalis penis*.

VIRGATA *Sutura*, a term used by some anatomists for the sagittal suture of the cranium.

VIRGILIAN *Husbandry*. See the article HUSBANDRY.

VIRGINALE *Claustrum*, a term used by some writers to express the hymen.

VIRGINS-*Bower*, *Clematitis*, in botany, the name of a genus of plants; the characters of which are these: The flower is of the rosaceous kind, and usually consists of four leaves arranged in a circular form, and without a cup. The pistil arises from the center of the flower, and finally becomes a fruit composed of several seeds arranged into a sort of head, and each ending in a long plume.

The species of *Clematitis*, enumerated by Mr. Tournefort, are these: 1. The common broad-leaved wild *Clematitis*, with leaves indented. 2. The broad-leaved wild *Clematitis*, with leaves not indented at the edges. 3. The pear-tree-leaved indented *Clematitis*. 4. The creeping *Clematitis*, called by many authors flammula. 5. The creeping sea *Clematitis*. 6. The white flowered upright *Clematitis*. 7. The early red-stalked upright *Clematitis*. 8. The geranium-leaved alpine *Clematitis*. 9. The blue-flowered upright *Clematitis*. 10. The white-flowered upright *Clematitis*. 11. The blue-flowered procumbent *Clematitis*. 12. The purple procumbent *Clematitis*. 13. The double blue flowered *Clematitis*. 14. The double purplish-blue *Clematitis*. 15. The double pale-red *Clematitis*. 16. The upright dwarf Spanish *Clematitis*, with white flowers. 17. The narrow-leaved Portugal *Clematitis*, with small blue flowers.

Authors have added to this genus, the *Clematitis* trifolia flore roseo, which is properly a granadilla; and the *Clematitis* Daphnoides, which is a pervinca. *Tourn.* Inst. p. 293.

The several species of this plant make a very fine ornament in the quarters of gardens allotted to flowering shrubs. They are all propagated, by laying down their branches in spring, as is practised in vines and other such shrubs; and in a year's time they will have taken sufficient root, and may be taken up and removed to the places where they are to remain. This should be done in spring, and a little mulch must be laid about their roots, and they must be watered in dry weather. In two years after planting they will make very strong shoots, which are to be trained up to stakes, that they may not trail upon the ground. After this, they require no farther care, than to cut out their dead branches every year, and in the spring to shorten such branches as are too long and rambling.

They may also be raised from seeds, sown either as soon as ripe, or in the spring; but this is a more tedious way, as they lie six or twelve months in the ground before they appear, and after that require two years care in a nursery-bed before they are fit to be planted out where they are to stand.

VIRIDELLUS, a word used by some medical writers, to express the epilepsy; and by some of the chemical ones, as a name for the common green vitriol.

VIRILIS *Testis Musculus*, in anatomy, a name given by Vesalius, and others, to the muscle generally known by the name of the *Cremaster*.

VIRITES, a name by which the writers of the middle ages have called the Pyrites.

VISCAGO, in botany, the name of a genus of plants, described by Dillenius, and since called by Linnæus *Silene*. *Dillen.* Hort. Elth. p. 309. See the article SILENE.

VISCAGO is also used by some pharmaceutic writers, to express a mucilage.

VISCERA (*Cycl.*)—*Wounds of the* VISCERA. If any of the *Viscera* situated in the abdomen, as the liver, spleen, or kidney, has received a wound from a sharp instrument, at the first dressing the wound must be filled as tenderly as possible with lint well saturated with highly rectified spirit of wine, or spirit of turpentine, securing the dressings with compresses and a bandage; by this means the hæmorrhage will be stopped, if no large vessel is divided. When this part is gained, the wound must be treated in the common manner, and the patient kept very low; bleeding him, if of a plethoric habit, and giving daily two or three doses of Lucatellus's balsam; for balsams of this kind are of great service in healing internal wounds. This is the method to be taken with wounds of the *Viscera*, which may be discovered by the eye or touch. But in such of them as are hidden, and not to be thus discovered, all that can be done is to inject vulnerary decoctions, and keep a passage open for the evacuation of sordes, or grumous blood. *Heister*'s Surg. p. 68.

VISCERALIA, a term used by physicians, to denote such medicines as impart strength and firmness to the sanguineous *Viscera*, such as the liver, spleen, &c.

VISCERATIONES, among the Romans, a feast consisting of the intrails of animals, given to the people at the burial of great men in Rome. *Danet.* in voc.

VISCUM, *Misletoe*, in botany, the name of a genus of plants; the characters of which are these: The flower consists of one leaf, hollowed into the shape of a bason, and usually divided into four segments at the edge, and sprinkled over with apices in the form of little protuberances. The embryo fruits do not succeed there, but appear on other plants of the same species, and are surrounded with four little leaves; these finally become round berries full of a glutinous juice, and containing flatted and heart-fashioned seeds.

The species of *Misletoe*, enumerated by Mr. Tournefort, are these: 1. The common, or white-berry'd *Misletoe*; and 2. The *Misletoe* with red berries. *Tourn.* Inst. p. 609. See the article MISLETOE.

VISCUM is also used for *Birdlime*. This was esteemed a poison among the antient Greeks, and is seldom omitted under the class of deleterious things enumerated in their writings.

It is called by these authors *Ixias*; but this word has occasioned great errors in late writers, the word *Ixias* having been applied for the white camelion thistle, not because of any poisonous quality it had; for they all declare it to be innocent, but because of its yielding a viscous, or clammy juice. The black chamæleon thistle was always esteemed poisonous among them; and hence some have supposed the word *Ixias* to be applied to that, and the poison *Ixias*, mentioned by the Greeks, to be the root of that plant. Paulus Ægineta indeed seems to have understood it so, the poison *Ixias* being by him placed among the roots; but Galen, who calls it a slow poison, and says, that it kills by stopping up and glewing together the intestines, plainly enough means *Birdlime*, not the root of any plant.

VISCUM *Caryophylloides*, a name given by Sir Hans Sloane, and many other authors, to a genus of plants of a very peculiar kind. They are called *Viscum* from their growing upon other trees, in the manner that the misletoe does with us; and *Caryophylloides*, from their leaves, in some degree resembling those of our pinks or carnations; but the plant itself, in all its species, is wholly different, both from the misletoe and pink, in all other respects.

The several species of these plants differ greatly also from one another; the most fragrant species in Jamaica is a very large one called by the common people, the wild pine. The root of this plant is composed of a great number of brown filaments, which encompass the whole branch of the tree on which it grows; these are very different from the roots of our misletoe, for they enter into the solid substance of the tree, but the roots of the misletoe are expanded over its surface, and are often confusedly interwoven one with another. The roots of *Viscum* give a very firm basis for the plant, and from these there arise the rudiments of the leaves, which at length grow to the likeness of those of leeks, or of the leaves of some of the aloes, being folded one within another; they in some sort also resemble those of the pine-apple, or ananas, and it is on this account that the plant is called the wild pine. These leaves are between two and three foot long, and are three inches broad at the base, from whence they run tapering all the way, till they terminate in a point; they are very round or convex on the outside, and very hollow within; by means of this shape of the leaves is formed a very fine reservatory of water in every plant of this kind.

All the leaves being thus hollow within, and standing in a circle at the bottom, form a round hollow mass, which swells out into a sort of bulb, looking like a turnep, except in colour, and very large; they afterwards draw nearer to the stalk, and form by that a sort of neck to this bottle cavity, which is close and firm on all sides: in the rains, the trees on which these plants grow, drop off vast quantities of water from their leaves, and this is in great plenty catched by one or other of the long leaves of this plant; each of which is a sort of hollow pipe, conveying all that it receives into the bottle, or reservoir at the bottom; this soon runs over, but in consequence of this, it is at last left full, and this water it retains a long time, by means of the narrow neck they form above, which prevents the evaporation that would otherwise naturally happen by the sun's heat: this water gives a continual supply of juices to the leaves, which are of a pale green in the bottle part, and as green as a leek above.

In the midst of these leaves rises a smooth branched and succulent stalk of about three foot long; this, when wounded, yields a white mucilaginous juice; the flowers are numerous, and consist each of three leaves, standing in a three-leaved green cup; after these come three corner'd capsules; at the base of this are three small and short leaves, and within it are contained several seeds, of an oblong, pyramidal form, small in themselves, but winged with a very long and fine down. The plant is very common in woods and forests, and grows usually to the branches, but sometimes to the trunks of the trees, especially when they are somewhat decayed, their bark then more easily receiving the seed, and giving a free passage to the roots. Phil. Trans. N°. 252. p. 114. See the article SOWING.

VISION (*Cycl.*)—*Distinct* VISION, that by which an object is seen distinctly. An object is said to be seen distinctly, when its outlines appear clear and well defined, and the several parts of it, if not too small, are plainly distinguishable, so that we can easily compare them one with another, in respect to their figure, size, and colour. Dr. *Jurin*'s Ess. on dist. and indist. Vision.

In order to such *distinct Vision*, it has hitherto been commonly thought, that all the rays of a pencil, flowing from a physical point of an object, must be exactly united in a physical, or at least, in a sensible point of the retina. But it seems certain,

certain, from the experiment mentioned by Dr. Jurin, that fuch an exact union of rays is not always neceffary to *diftinct Vifion*.

Hence the doctor divides *diftinct Vifion* into two fpecies, *viz.* into *Vifion perfectly diftinct*, or *perfect Vifion*, and *Vifion imperfectly diftinct*; which he calls fimply by the name of *diftinct Vifion*. The former, is that in which the rays of each pencil are collected into a fingle phyfical, or fenfible point of the retina; the other fpecies, is that in which thofe rays occupy fome larger fpace upon the retina, yet fo far as the object is diftinctly perceived.

Perfect *Vifion* in a given eye, and a given difpofition of that eye, depends only upon the diftance of the object; it has no dependance upon the magnitude of the object; but diftinct *Vifion*, in a given eye, and a given difpofition of the eye, depends upon the diftance and magnitude of the object jointly.

There appearing therefore a real difference between perfect *Vifion*, and what we call *diftinct Vifion*, the learned doctor has enquired very particularly into the reafon why an object may be feen diftinctly without perfect *Vifion*; for which we refer to his effay at the end of Dr. *Smith*'s Opticks.

VISITATION (*Cycl.*) — The *Vifitation* of the Virgin Mary is a feaft inftituted firft by pope Urban IV. in the year 1389. and ordained to be kept on the fecond of July. *Hofm.* Lex. in voc.

VISITATION is likewife an order of monks founded by Francis de Sales and his mother Chantalia. Id. ibid.

VISPELLIONES, among the Romans, were flaves who could not be manumitted. *Pitifc.*

VISTAMENTE, in the Italian mufic, is ufed to give notice to play, or fing, quick, brifkly, &c.

VISTE, in botany, a name given by fome authors to the common white mountain coralloides: it is the Lapland name for the fame plant; the rain-deer, and many other creatures feeding on it when all other vegetables are deftroyed.

VITA (*Cycl.*)— VITA *longa*, a name given by fome botanical authors to the *piper Æthiopicum*, or Æthiopian pepper. Gen. Herb. p. 1335.

VITALBA, in botany, a name given by fome authors to the viorna, or traveller's joy, a tall climbing plant with white flowers, common in the hedges. *Ger.* Emac. Ind. 2.

VITALIA, a name given by fome authors to the cardiac medicines.

VITALIS, in botany, a name given by fome authors to the common telephium, called in Englifh *Orpine*, and live-long, from its quality of living and flourifhing a long time after it is taken from the root. *Ger.* Emac. Ind. 2.

VITEX, the *chafte Tree*, in botany, the name of a genus of trees; the characters of which are thefe: The flower confifts of one leaf, and is, as it were, bilabiated, and tubular behind; the piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; this finally becomes a roundifh fruit, divided into four cells, each containing oblong feeds.

The fpecies of *Vitex*, enumerated by Mr. Tournefort, are thefe: 1. The *Vitex*, with broad ferrated leaves. 2. The *Vitex*, with narrower leaves, difpofed in the manner of thofe of hemp. 3. The narrow hemp-like leaved *Vitex*, with bluifh flowers. 4. The white flowered *Vitex*: and 5. The *Vitex*, with extremely narrow leaves. *Tournef.* Inft. p. 603. See the article AGNUS *Caftus*.

VITIFERA, in zoology, a name by which many have called the common œnanthe, a bird well known in England by the name of the wheat-ear; and called in fome places the fallow-finch and white-tail. See the article WHEAT-*Ear*.

VITILIGO, a difeafe frequent among the Arabians: it is the fame with what is otherwife called *Alphos*. *Hofm.* Lex. in voc. See the article ALPHOS, *Cycl.* & *Suppl.*

VITIS, the *Vine*, the name of a genus of plants; the characters of which are thefe: The flower is of the rofaceous kind, and is compofed of feveral petals, arranged in a circular form; from the middle of the flower there arifes a piftil, which is furrounded by a number of ftamina; this finally becomes a round, fucculent, or juicy berry, containing ufually four pear-fafhioned feeds. See the article VINE.

The fpecies of *Vine* enumerated by Mr. Tournefort, are thefe: 1. The common, or wild *Vine*. 2. The Corinthian, or currant *Vine*. 3. The parfley *Vine*, or *Vine* with deeply laciniated leaves. 4. The early *Vine*. 5. The damafk *Vine*. 6. The mufkatel, or Apian *Vine*. 7. The Pergulane *Vine*, with fruit of the fize and fhape of plums. 8. The African *Vine*. 9. The Allobrogic *Vine*. 10. The large bunched *Vine*, with white fweet and firm grapes. 11. The large bunched *Vine*, with redifh, or blackifh fweet grapes. 12. The large bunched, with whitifh oval grapes. 13. The hairy *Vine*. 14. The climbing five-leaved Canada vine. 15. The maple-leaved Canada *Vine*. 16. The abutilon-leaved Canada *Vine*, with purple grapes. 17. The American *Vine*, with ferrated ivy-like leaves. 18. The round leaved American *Vine*, with blue cluftered grapes. 19. The great, trifoliate, American *Vine*, with fmall round grapes in large clufters. 20. The fmaller trifoliate American *Vine*, with larger turbinated grapes difpofed in clufters. 21. The fow-bread leaved American *Vine*, with racemofe corymbi of black grapes. *Tourn.* Inft. p. 613. See the article VINE.

VITIS *Idæa*, the *Whortle*, in botany, the name of a genus of plants; the characters of which are thefe: The flower confifts of one leaf, and is of the globofe campaniform kind. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower; the cup finally becomes a foft umbilicated berry, juicy, and containing fmall feeds.

The fpecies of *Vitis Idæa*, enumerated by Mr. *Tournefort*, are thefe: 1. The *Whortle*, with oblong crenated leaves, and black fruit. 2. The *Whortle*, with roundifh, and not crenated leaves, and with red fruit. 3. The long leaved white berry'd *Whortle*. 4. The great round leaved *Whortle*. 5. The fweet-fcented *Whortle* of Ceylon. 6. The pyrola-leaved Canada *Whortle*: and 7. The myrtle-leaved Canada *Whortle*. *Tourn.* Inft. p. 608.

VITISALTUS, a word ufed by fome medical writers for the *Chorea fancti Viti*. See the article VITUS's *Dance*.

VITRAGO, in botany, a fpecies of plants, refembling that of which the glafs is made. It is otherwife called *Helxine*. *Hofm.* Lex. in voc. See the article HELXINE.

VITREA *Tabula*, a name given by fome authors to the internal table of the cranium.

VITREUS *Humor*, the *vitreous humour* of the eye. See the article EYE.

VITRIOL (*Cycl.*)—The manner of making the common green *Vitriol*, or copperas, at Bricklefy in Effex, is this: They gather the pyrites, or copperas ftone on the fhores of Shepey-Ifland, and in other places; and this they lay upon a large bed, or floor prepared in the open air, underneath which there are gutters, or troughs difperfed to receive and carry away the liquor impregnated with the mineral, to a ciftern where it is kept till worked.

The air and weather diffolves, and breaks thefe ftones; and the rain falling on them, wafhes gradually out all the *Vitriol*; which is thus feparated from it: they boil the liquor in large leaden pans, putting in a great quantity of old iron, and when fufficiently evaporated, they let it out into troughs, where the *Vitriol* feparates itfelf, and cryftalizes, fticking to the fides of the troughs, and to fticks and bars placed acrofs them. The remaining liquor they call the mother of *Vitriol*, and fave it to be afterwards boiled and evaporated again. *Ray*'s Englifh Words, p. 139.

There is contained in the original liquor, of which *Vitriol* is made from the pyrites, a white, acrid, and pungent falt. This is feparated from the mother liquor, or brine, when no more *Vitriol* will fhoot; and is called by the chemifts, the faline principle of *Vitriol*.

Common green *Vitriol*, when diffolved in water, and feparated from its metalline, and ochreous, or earthy particles, by zink, or any other of the imperfect metals, added in filings to the folution, is then much of the nature of this white falt, called the faline principle: it is white, not green, more unctuous than the common *Vitriol*, and has a grain rather appearing like nitre than like *Vitriol*.

The native white *Vitriol* of Goffelaer has alfo fomewhat of this nature in it, having lefs metal, and much lefs mineral fulphur than the common green, or blue *Vitriols*. The common *Vitriol*, thus feparated from its earthy and metalline parts, will yield its fpirit eafily, and with the gentle heat of a fand furnace; as the white falt extracted from the mother liquor of *Vitriol* will: whereas, in the common *Vitriol*, the metalline part fo detains the faline, that it cannot be driven off in form of vapour, till that compages is broken, by a very intenfe and violent heat; what remains in the retort after the diftillation of either this or the other falt, is not red like colcothar of *Vitriol*, but is white and fpungy, and rather refembles burnt alum, than any other fubftance, in its appearance. It is infipid when firft taken out of the veffel; but on being expofed to the air, it receives ftrange impreffions and alterations. Phil. Tranf. N°. 103. See the article SALINE *Principle*.

There is great reafon to believe, that *Vitriols* are no other than metals of different kinds, penetrated and reduced into a new form by fulphur. If thin plates of copper be cemented with beds of brimftone between, and the operation repeated four or five times with frefh brimftone every time, moft of the copper will be converted into *Vitriol*; and this diffolved in water, filtrated and cryftallized, will afford elegant rhomboidal blue cryftals, no way diftinguifhable from common blue *Vitriol*.

The fame procefs may be repeated with iron inftead of copper, and the *Vitriol* will then be the common green kind, or copperas; or if the acid liquor, called fpirit, or oil of fulphur by the bell, be rubbed on plates of iron or copper, and fuffered to dry away in the air, or over a gentle heat, and this repeated three or four times, the metal being afterwards put into water, will be fo far corroded and diffolved by it, that there will be a liquor produced, which will yield, on a proper evaporation, blue or green cryftals, according as iron or copper have been ufed. This fhews evidently, that the metal thus corroded by the acid of *Vitriol*, is foluble in water, fo far as it has been fo corroded; and that this folution affords true *Vitriol*. Such may be the formation of *Vitriol* about the copper mines in many countries, and fuch the formation of the common green *Vi-*

triol or copperas in the pyrites with us in England. That stone is well known to contain sulphur and iron, both in large quantity; and the combination of these in the earth, or in the air, where moisture enough can get at them, may very well be understood to form *Vitriol*, which is the natural result of such a solution. Phil. Transf. N°. 104.

It is observable, that before metallic *Vitriols* are dissolved in water, they cannot be perfectly dried without changing their nature; and when dissolved, they constantly let fall much ochre to the bottom; so that by repeated solution and crystallization of *Vitriol* in water, all the *Vitriol* is at length turned into ochre, and an unctuous liquor, that cannot easily be dried. Whence the easier, the quicker, and with the less water, some salts are dissolved, the more easily they retain their water.

There is also something particular in the solution of metals by water, for certain salts are required to dissolve them; and when they are dissolved into crystals of *Vitriol*, they then readily and easily dissolve in water, so long as these crystals retain that salt which is the solvent of the metal; but when this saline solvent is wanting in the *Vitriols*, water will scarce dissolve them at all, but suffers the metallic part to precipitate; but when the metal is previously dissolved by its own solvent salt, it readily yields to water, and may thus, by a gentle evaporation, be reduced to crystals, wherein the metal, its solvent, and water always concur in a certain proportion. By this method metals are made potable, and act in the body as well, according to the acid solvent, as to the nature of the metal dissolved. The action of all *Vitriols* depends thus upon these two principles united with water; and of this kind are the *Vitriols* of gold, silver, copper, iron, lead, and tin.

This rule does not extend, however, to all the *Vitriols*; for those of the semi-metals, though they are first dissolved by their acid solvents, so as to appear in a saline form, cannot therefore be diluted with water like the salts of the true metals; Thus pure regulus of antimony, perfectly dissolved in spirit of sea-salt, adhering to the mercury sublimate, in the distillation of the butter of antimony, is a true *Vitriol* composed of antimony, dissolved in spirit of sea-salt: Whence one might suspect, that it would dissolve in water; but, on the contrary, as soon as water touches it, the acid solvent quits the regulus, mixes with the water, and lets fall the metallic calx entire. *Boerhaave*, Chem. part 1. p. 451.

Liquamen Pyriticum, or mother of *Vitriol*, is of an acrid and firey taste, very different from that of *Vitriol*, and has been proved by some late experiments, to contain a salt very different from the *Vitriol*. The method of separating this pure, is to evaporate a quantity of the water, impregnated with *Vitriol*, and received from the beds of the pyrites; this being evaporated to a pellicle, the *Vitriol* will shoot in the cold, and a quantity of ochre will be precipitated. After this, succeeding evaporations will yield more *Vitriol* and more ochre, to the fifth time; but if the experiment be continued after this, the first succeeding shooting of the liquor yields, instead of *Vitriol*, a yellow salt.

This contains the last portion of the ochre remaining in the liquor. After this, the matter yielding no more *Vitriol*, is called the wash, or *Liquamen of Vitriol*. It tastes acrid and firey, and the quantity left from a gallon of the well impregnated liquor from the bed, is about a pound. From this may be procured a white pungent salt, by subsequent evaporations. This is the saline principle of *Vitriol*, according to the chemists, and is contained in so large a quantity, that near thirteen ounces of it may be separated from a pound of the liquor; the remaining liquor, after this, is what is called *Liquamen Vitrioli* by some chemists, but not properly. It will never coagulate into salt, but is very firy and acrid to the taste, and extremely ponderous, not less so than oil of *Vitriol*, nor less pungent; and is the strongest liquor any way obtained from a natural substance without distillation. This liquor being exposed to the air in a vessel not closed, will in a little time attract double its weight of water from it. All corrosive and saline liquors have somewhat of this property of imbibing moisture from the air, and weakening themselves by it; but this liquor attracts it faster and in greater quantity than any other. This liquor receives most moisture, and inceases most quickly in wet weather, less so in dry; and this may have given occasion to that error so common among the chemists, that several preparations of *Vitriol* derive moisture from the moon, and have more or less of it, according to her different phases. The changes of the constitution of the air have effected what, in this case, they supposed to be done by the different phases of the moon. Phil. Transf. N°. 103.

Vitriol *of Copper*. The glass-makers have a method of making this without corrosives, which was originally practised by Neri, and with which they make some very fine colours in glass, particularly a fine sea-green.

The method of making the preparation is this: Take little thin pieces of brass, and lay them *stratum super stratum* in a crucible, with powder of brimstone. When the vessel is full, set it luted and covered in an open wind furnace, with burning coals over it, and let it stand two hours; then let the furnace cool of itself, and take out the crucible, the mass within will be of an obscure blackish purple; powder and sift it fine, and then mixing with every pound of it six ounces of powdered brimstone, take a round vessel of earth, that will bear the fire, place it upon iron bars set across in an open wind furnace, fill it with coals, and then put in the powder; keep it burning and stirring about till all the brimstone is burnt up; then take out the pan, and powder the calcined mass again; sift it fine, and proceed with it thrice as before; the last time let it stand on the fire till it become red. Put a pound of this calcined copper into a glass body, with six pints of water; evaporate two pints or thereabout in a sand heat; the water is then of a fine blue, and must be poured off clear; then filtrate it. Evaporate the water from the remaining sediment of copper left in the glass, and with new sulphur calcine it again and again; repeat this five or six times, and extract the blue tincture with water as before; filtrate all the waters, and put them together. Evaporate all to a fifth part or thereabouts, and set it in a cool place, and fine pointed crystals will be formed, resembling emeralds; separate these crystals, and evaporate the water again, till all the crystals be procured. Then put a pound of them into a glass retort, well luted and fitted to a capacious receiver; let the joints be well closed, and make a moderate fire for four hours; then make it violent for twenty hours, or till no more white fumes arise. The next day open the receiver, and separate the liquor into a glass, where it must be kept carefully sealed up. *Neri*'s Art of Glass, p. 50.

Very great things are to be done in the glass art by means of this liquor; the remainder in the retort exposed to the air for a few days, will acquire a blue colour, and this, mixed with zaffer, will give glass a fine sea-green.

White Vitriol. It has been disputed whether *white Vitriol* is any thing else than green *Vitriol* calcined. But it seems that *white Vitriol* is of a quite different species from either the green or the blue *Vitriols*. See *Geoffroy*, Mat. Med. Tom. 1. p. 124.

In the condition in which *white Vitriol* is usually bought, it contains somewhat both of copper and iron; but, being purified by solution, filtration and crystallization, it is freed from both these metals, and appears to be a native *Vitriol sui generis*. See *Cramer*, Elem. Art. Docim. vol. 1. p. 302. ed. 2. Med. Ess. Edinb. Abr. vol. 2. p. 472.

If four ounces of alum be put in concoction with two parts of *cadmia fossilis* pulverized, the earth of the alum precipitates, and its acid takes hold of the earth of zinc, so that a true *white Vitriol* is the result.

This *Vitriol* being precipitated by an alkaline lye, and dried, after its salts are separated in water, and then mixed with charcoal-dust, it will give zinc, in the manner mentioned under the article Zinc.

The same thing happens in mixing *Vitriol* of iron with two or three parts of lapis calaminaris; but the operation is easier with alum and *Vitriol* of copper. *Marggraf.* in Mem. de l'Acad. de Berlin, 1746.

Blue Vitriol is made by evaporating ziment-water to a proper standard; after which it is let out into coolers, where it shoots into regular and beautiful crystals of a rhomboidal form, and composed of ten planes. These have the same qualities with the water; and being dissolved in common water, they make a ziment liquor, undistinguishable from the native kind. See the article Ziment-*Water*.

Blue Vitriol is also contained in sory or rusma, and many of the pyritæ and marcasites or mundics, but seldom pure. There are also some earths which contain it, but they principally owe it to ziment-waters passing through them.

Blue Vitriol has copper for its basis, and is never used internally, but only in external applications. There are several preparations of it recommended in dispensatories, the most valuable of which seems to be the *aqua Vitriolica cerulea*. See the article Aqua.

Vitriol *of Quicksilver*, the name of a chemical preparation of quicksilver, with acid spirits, the process of which is this: Let so rich a solution of quicksilver be made in spirit of nitre, or aqua-fortis, that no more can be contained; let this solution be made by the assistance of heat, and the liquor immediately afterwards poured off into a clean and cold glass. There will, on this, spontaneously shoot on the bottom of the glass a saline white transparent matter, from which the liquor being poured, it is found to be a sharp moist saline substance, or true *Vitriol* of mercury, soluble in water, and not safe to be touched: If the liquor, poured off from this, be evaporated half away, and the remainder set in a cool place, more crystals of the same nature with the first will shoot.

Another method of making the *Vitriol* of mercury, is this: Reduce to powder some decrepitated sea-salt, and with two parts of this mix one part of crude mercury; distil the whole in a glass body, with a strong fire, continued for five or six hours; when the vessels are cold, break them, and there will be found a solid dry mercury, sublimed to the top and sides of the body, in form of *Vitriol*: Nay, Boerhaave affirms, that the common mercury sublimate is a true *Vitriol* of mercury, though semi-volatile. *Boerh.* Chem. part 2. p. 301.

Preparations of Vitriol are, 1. The acid spirit, or oil of *Vitriol*. 2. Colcothar, or calcined *Vitriol*. 3 *Tartarum Vitriolatum*. 4. *Spiritus Vitrioli dulcis*. 5. The compound

triolatum.

ſpirit of *Vitriol*. See the articles SPIRIT, COLCOTHAR, &c. *Cycl.* and *Suppl.*

Oil of VITRIOL. Mr. Boyle informs us, that if the caput mortuum, after the diſtillation of the *oil of Vitriol*, be ſuffered to lie a conſiderable time in the air, it will be ſo impregnated with new ſaline particles, as to be worth a ſecond diſtillation. Works abr. vol. I. p. 142.

This ſtrong acid, when expoſed to the air, attracts the moiſture from it in very great quantity, increaſing in weight gradually to more than three times what it was when firſt expoſed, and gradually diminiſhing in ſtrength. The quantity of water it attracts from the air, in any given time, is not, however, in proportion to its own quantity, but to its ſurface; and Mr. Boyle has found by experiment, that if the ſame quantities be expoſed to the ſame air in glaſſes, in the one of which the ſurface is nine times greater than the other, that with the larger ſurface will gain eighteen grains addition in weight, while the other gains only two grains; and ſo in proportion for any longer time.

When the oil of *Vitriol* is fully ſatiated in the moiſteſt air, or wetteſt weather, it afterwards retains or loſes its acquired weight, as the air proves more or leſs moiſt. It may therefore be very practicable to make it a means to eſtimate the moiſture and dryneſs of the air. A very eaſy machine may be contrived to anſwer this purpoſe; for even a common pair of ſcales will do very well; and by a ſcale, on which the tongue of the balance ſhould move, would mark out the ſmalleſt changes in the moſt nice and accurate manner.

If a quantity of *oil of Vitriol* be expoſed in a wide-mouthed glaſs, till thoroughly ſated with the moiſture of the air, and then put into a ſcale, and in the moiſteſt weather exactly poiſed with a weight in the oppoſite ſcale, it will only continue exactly poiſed ſo long as the weather continues in that moiſt ſtate; but as the air becomes gradually more and more dry, it will weigh leſs and leſs, and mount, while the ſcale with the weights preponderates and ſinks.

The tongue of a ballance of but an inch and half long, thus deſcribes an arch of the third of an inch, by the different riſing and falling of the ſcale in which the *oil of Vitriol* is; and conſequently if the tongue were a foot long, it would deſcribe an arch of near three inches, which would be a ſufficient ſpace to mark a ſcale of degrees very nicely upon; and, as the tongue is pointed to theſe, it would be an excellent hygrometer.

This ballance may be contrived two ways, either ſuch whoſe pin ſhould be in the middle of the beam, with a very ſlender tapering tongue, of a foot or a foot and half long, pointed to the diviſions on a broad arched place fixed above; or elſe the ſcale with the liquor may be hung to a point of the beam, very near the pin, and the other extreme made ſo long as to mark a large arch on a board, placed conveniently for that purpoſe; and the ſcale, in either caſe, may very conveniently be a concave glaſs of four or five inches in diameter. On the diviſion of the arches ſhould be inſcribed the different temperature of the air ſhewn by the liquor. Phil. Tranſ. N°. 157.

The oil of *Vitriol*, being a cauſtic of an oppoſite nature to *lapis infernalis*, has been known to remove the pain occaſioned by the application of the latter. See the article OPPOSITE *Cauſtics*.

VITRIOLIC (*Cycl*) —VITRIOLIC *Minerals* are compound foſſile ſubſtances, formed of various ſtony and earthy particles, mixed with others of iron and copper, and that either ſeparately or conjunctly; ſo that, in effect, they are ores of *Vitriols*.

The different kinds of theſe minerals are, 1. The chalcites. 2. The miſy. 3 Sory or ruſma. 4. Melanteria. 5. Pyrites, or fire-ſtone. 6. Marcaſites. See the articles CHALCITIS, MISY, &c. *Cycl.* and *Suppl.*

In Europe the only uſe made of chalcitis is as an ingredient of Venice-treacle, and even here its place is generally ſupplied with common green *Vitriol* calcined to a redneſs. The antient Greeks uſed it externally in hæmorrhages and collyriums for the eyes; alſo for the herpes and eryſipelas; but never ventured to give it internally.

The antients uſed *miſy* for the ſame purpoſes as *chalcitis*, being eſteemed milder than this laſt.

At preſent it is no where put to any uſe, nor indeed does it merit it, as containing no other virtues than thoſe of green *Vitriol*, though we are not ſure what pernicious ſubſtance it may be mixed with.

VITRIOLIC *Waters*. The countries which abound with mines of copper and iron uſually afford a great many *vitriolic* waters.

One of the moſt remarkable ſprings of this kind, of which we have an account, is that near Padderborn in Germany: This is a ſort of treble ſpring, having three openings, and all three yielding very different waters. Two of theſe openings are not more than a foot and half diſtant from one another, and yet of ſo different qualities, that the one is limpid, bluiſh, milk-warm, and bubbling, and contains ſal armoniac, ochre, iron, vitriol, alum, ſulphur, nitre and orpiment; all theſe ſubſtances having been ſeparated in its analyſis. The other is cold as ice, and is turbid, whitiſh, and much heavier, and ſtronger to the taſte than the other. This holds much orpiment, with ſome ſalt, alum, nitre, ſal armoniac, and vitriol. The firſt of theſe waters is taken by the people in the neighbourhood, againſt worms, and diſorders of the ſpleen, as alſo againſt epilepſies; the other is poiſonous to birds, all that drink of it dying in a very little time. The experiment has been tried on common hens, with the water brought from the ſprings into other places, and given them to drink.

Thoſe to which ſalt is given, after the ſwallowing this poiſonous water, ſtruggle longer before they die by it; and vinegar is found to ſave them very often from death, after drinking largely of it; but in this caſe they are ſickly for ſeven or eight days after it, and have the pip, as the good women expreſs it.

In the diſſecting thoſe birds which have died by drinking this water, the lungs are always found quite ſhrivelled up.

The people of the country have not been deterred by this bad effect of the water, from uſing it in medicine; they take ſmall quantities of it diluted in water, to deſtroy the worms, and it performs this very well; but gives them a grievous ſickneſs while it operates.

The third ſtream, or opening of this remarkable ſpring, is about twenty paces diſtant from the others; the water is here very clear, of a greeniſh colour, and of a ſour, but not very diſagreeable taſte. It is of a middle weight, and of middle qualities between the other two, and is evidently formed of the joining of thoſe two ſprings with ſome other freſh water in the way; for a liquor exactly reſembling this third kind may be prepared, by mixing equal quantities of the other two with a ſufficient quantity of commom well-water. Phil. Tranſ. N°. 8.

There is a ſpring in Baſil diſcharging its water through the tanners-ſtreet, or gerber-gaſſe, which is of a bluiſh colour, and ſomewhat turbid. This holds blue vitriol, that is, copper, in the form of a ſalt, and with it bitumen and antimony; but a much larger proportion of the firſt ingredient, than of either of the others. The analyſis of it ſhews, that it contains three parts copper to one of bitumen, and two of antimony. It ſerves the tanners of the place to good purpoſe, their ſkins receiving one of their preparations from this native water.

The ſame town affords ſeveral other ſprings of peculiar qualities, all owing to the veins of metalline ores, with which the earth of the place abounds. The one of theſe is called *Bandulph's-well*, and affords a water of great uſe in medicine, ſeveral being regularly and perfectly cured of hydropical diſtempers by it. And another very remarkable one contains, as is found by its analyſis, ſulphur, nitre, and ſome gold. Theſe, however, are in ſuch ſmall quantity in it, as not to prevent its being fit for the common uſes of life. It is very ageeable to the taſte, and is much eſteemed for drinking, and ſent for all over the town.

Another *vitriolic* water runs out of a cavern near Gelſbach in Alſace. It is a fattiſh and oily liquor, and is uſed by the country-people for greaſing their wheels; but it is fit for much better purpoſes. If it be boiled to the evaporation of a third part, there will remain very little water, but a fatty bituminous ſubſtance, like tar, will ſubſide to the bottom, and there will ſwim at the top a yellow, thin, and limpid liquor, very much reſembling linſeed oil; and this, diſtilled in a ſand heat, yields an oily and watry liquor; the firſt very good for external uſes, for burns and ſcalds; and the other a good internal medicine, in conſumptions, and other diſeaſes of the lungs. Id. Ibid.

Some time ago there was a water diſcovered in England, that gave, on many experiments, an appearance of containing natural and perfect vitriol. This water was found near Eglingham in Cumberland; and being examined, by adding galls to it, it became abſolute ink, much deeper than any of the atramentous waters ever do: When one half the quantity was ſlowly evaporated, the remainder retained this quality to a higher degree than before; and, on evaporating it yet farther, there concreted in it fair cryſtals of pure and genuine vitriol.

This was an appearance wholly new in England, and not eaſily accounted for, as we have no mineral, except the common pyrites, which contains vitriol; and it is very well known, that there requires a fermentation in the air, before the vitriol, contained in that ſtone, will be diſintangled from its other principles, ſo as to be capable of appearing in its own form; and as this ſtone, lying under water, can never impregnate that water with its vitriol, it did not ſeem eaſy to conceive in what manner a genuine vitriol ſhould be communicated to water, where there was no other ſubſtance which could give it.

The ſuſpicions that theſe thoughts gave the gentleman who examined this water, occaſioned his making a viſit to the place where it was produced, when he found that the ſuppoſed *vitriolic* ſpring was no other than an old drift made for the draining the water from ſome old wrought coal-pits; the people who had worked in theſe, remembered to have ſeen great quantity of pyrites there. This drift was ſometimes dry for a conſiderable time together, and ſometimes run in a plentiful ſtream; and there is no doubt but that, in theſe dry ſeaſons, the air acted upon the pyrites, and cauſed it to ſhoot its vitriol, which the next tide of water waſhed away, and it came off diſſolved in it, and highly impregnating it.

This proved therefore no better a medicinal ſpring than ſome of a like kind, deſcribed by Mr. Leigh in his natural hiſtory of

of Lancafhire; and all thefe are very little better than the difcovery of a medicated water in Oldftreet, from the remains of an old colour-fhop, or Kircher's reckoning the common fhores of Rome among the medicated fprings of Italy.

The *vitriolic* fpring which has been fo much talked of near Haigh in Lancafhire, is no other than an accidental impregnation of common water, in the fame manner, it being only the runnings of an old drift, or drain, made to carry off the water from fome pits of cannel-coal; and this, like the other, as it fometimes has water, and at other times is dry, gives time for the pyrites to let go its vitriol while dry, and then imparts it to the waters that pafs that way afterwards. Thefe are not to be accounted medicated fprings, fince neither natural nor continual, and fuch may be any day made at home, by laying the common pyritæ of our clay, or coal-pits, out to moulder in the air, and then pouring water upon it, and after a fhort time ftanding, taking it off again. Phil. Tranf. N°. 245. p. 380.

VITRUM, in botany, a name given by fome of the old writers to the plant we now call *glaftum* or *woad*.

This plant has always been a native of England, and was in ufe among the favage inhabitants of this ifland, for painting their bodies. Thofe who have not underftood this to be the name of that plant, have been ftrangely perplexed to account for thefe people's painting their bodies with *Vitrum*, glafs, as they underftood it: But the whole meaning of this plant obtaining the name of *Vitrum*, feems to have been its ftaining the fkin to a pale blue colour, or, as it was called by many, a glafs-colour.

VITRUM, *Glafs*. As impenetrable as glafs is to the common menftruums, we find it eaten by the air in length of time, when expofed in old windows; but the effects of its being kept in a fubterraneous place are much more ftrange. Borrichius tells us, that at the time when he was at Rome, there was dug up a whole houfe from under the kitchen-garden of a citizen. The houfe had been buried there ten ages, and there were found in it feveral glafs urns, or lachrymatories. The glafs of thefe had no holes made in it, as our old glafs in chamber-windows has, but ftill retained its fmooth furface and tranfparence; but it was fplit into a vaft number of thin laminæ, which were as pellucid and fine as Mufcovy glafs; and in fome places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the antient way of working their glafs; but it is not probable there could be any thing particular in the formation of the veffel, to determine it to fplit thus into flakes; but that glafs of the fame kind, in any form, would have done the fame. *Borrich.* de Ortu Chemiæ.

VITRUM *Antimonii Ceratum*, in pharmacy, is thus prepared: Take glafs of antimony in powder, one ounce, bees wax one dram; melt the wax in an iron ladle, then add the powder; fet them on a flow fire without flame, for the fpace of half an hour, continually ftirring them with a fpatula; then take it from the fire; pour it upon a piece of clean white paper, powder it, and keep it for ufe.

The glafs melts in the wax with a very flow fire. After the materials have been about twenty minutes on the fire, they begin to change colour, and in ten more come to the colour of fnuff; which is a mark of the medicine's being fufficiently prepared.

The ordinary dofe for adults is ten or twelve grains; but it is fafeft to begin with fix grains. The quantity of a fcruple has been given to a ftrong man, which wrought gently.

This medicine has for fome time been held a fpecific in dyfenteries; but the preparation and manner of giving it have been kept a fecret, till Dr. Young generoufly made it public. Dr. John Pringle fays, he tried it in a dyfentery of four years ftanding, with furprizing fuccefs. See Med. Eff. Edinb. vol. 5. art. 15.

It has been given in dyfenteries, with or without a fever, whether epidemic or otherwife, and whether bleeding and vomits have been premifed, or not. In its operation, it fometimes makes the patient fick, and vomits him; it purges almoft every perfon; but it has been known to cure without any evacuation or ficknefs. It is to be given with an empty ftomach, for then it operates moft mildly. Nothing is to be drank after it for three hours, unlefs the patient is very fick, and difpofed to vomit; in which cafe warm water may be given, as in other vomits.

This medicine fhould not be given for diarrhœas in the end of confumptions. Other diarrhœas have been cured with large dofes of it; but in fuch cafes it fails oftner than in dyfenteries. During the ufe of this powder, fermented liquors fhould be abftained from, and a milk diet is proper. See Medic. Eff. Edinb. ibid.

This preparation has alfo been found fuccefsful in uterine hæmorrhages, both in young and old.

It has alfo been tried in colic pains, from vifcidities in the inteftines, and found a fafe and eafy purgative, and fometimes a gentle emetic.

The method of giving it is in a bolus, with conferve of rofes, diafcordium, or theriaca Edinenfis. An opiate, after the operation, is proper. See Medic. Eff. or the Abridgment, vol. 1. p. 193. feq.

VITRUM *Morrhinum*, *Morrhine*, or *Myrrhine Glafs*, a name given by Pliny, and fome of the antients, to a fort of manufacture made in Egypt, which though truly no other than a kind of glafs divefted of its tranfparency, yet was made fo nicely to imitate the *myrra* or *morra* of the Indies, fo famous among the Romans, under the form of cups and veffels, called *murrhina vafa*, that it was called by fome, *murrha altera*, another fort of *murrha*, and the cups made of it honoured with the name of *murrhine veffels*. This ferves to fhew, that the *myrrhina vafa*, properly fo called, were not of any precious ftone, as vulgarly fuppofed, but of a fort of porcelain. See the article MORRINA.

VITTA, among the Romans, a fillet with which the women in Rome bound their hair. The matrons wore a double one, to diftinguifh them from the virgins, whofe *Vittæ* were fingle.

Vittæ were alfo worn by priefts and poets; in which cafe they were made of branches of olive or laurel; the ftatues of the gods were likewife adorned with *Vittæ*, as were altars, the doors of temples, victims and fupplicants. *Pitifc.* in voc.

VITTA *Cærulea*, in conchyliology, a fpecies of *dolium*. See the article DOLIUM.

VITTA, in ichthyology, a name given by Gaza, and fome others, to the fifh called by others, *tænia*, and by the Italians, *cepole*. See the articles TÆNIA and CEPOLE.

VITULUS *Marinus*, the *fea-calf*, in zoology. See the article PHOCA.

VITULUS, *Calf*, in zoology. See the article CALF.

VITULI *Aquatici*, in the hiftory of infects, a name given by the German writers to thofe flender and long worms found in waters, and refembling horfe-hairs, and which are fuppofed by the vulgar to be no other than real hairs, animated by lying in the water. We are not yet perfectly informed of all parts of their hiftory; but Dr. Lifter has found them in the bodies of feveral of the common beetles.

VITUS's *Dance*, or ST. VITUS's *Dance*, in medicine, the name of a peculiar fort of convulfion, to which young women are principally fubject, toward the time of the firft eruption of the menfes.

It feems to have had its name from the account which Horftius gives of fome women who once every year paid a vifit to the chapel of *St. Vitus* near Ulm, and there exercifed themfelves day and night in dancing, being difordered in mind, till they fell down like people in an extafy: By this means they were always reftored to health for a whole year, till the return of May, at which time they were again feized with a reftleffnefs, and diforderly motions of their limbs, fo as to be obliged, at the anniverfary of *St. Vitus*, to repair again to the faid chapel, for the fake of dancing. *Horftius*, Ep. Med. S. 7.

It is the moft frequent with girls, yet not peculiar to them, attacking boys alfo, from the age of ten to fourteen. It firft fhews itfelf by a fort of lamenefs, or rather unfteadinefs of one of the legs, which the patient draws after him like an idiot, and afterwards affects the hand on the fame fide; which being brought to the breaft, or any other part, can by no means be held in the fame pofture for a moment, but is diftorted or ftretched by a fort of convulfion to a different pofture and place, notwithftanding all poffible efforts to the contrary.

If a glafs of liquor be put into the patient's hand to drink, before he can get it to his mouth, he makes a hundred odd grimaces and geftures, for not being able to carry it ftrait, becaufe his hand is drawn different ways by the convulfion, as foon as it has reached his lips, he throws it fuddenly into his mouth, and drinks it very haftily, as if he meant only to divert the fpectators.

As this diforder appears to proceed from fome fharp humours thrown upon the nerves, which, by their irritation, excite preternatural motions, it feems that the curative indications are to be directed firft to leffen thofe humours by bleeding and purging, and fecondly, to ftrengthen the nervous fyftem. Dr. Sydenham therefore propofes the following method: Firft to take from the arm feven or eight ounces of blood, more or lefs, according to the ftrength of the patient. The next day let him take a gentle purge of rhubarb, fena, manna, &c. In the evening of this day, let him take a draught, with a fcruple of Venice-treacle, and eight drops of liquid laudanum mixed in honey and milk-water. This purging and opiate draught is to be repeated at fome days diftance, and the bleeding is alfo to be repeated to the fourth time; and in the intermediate days, a cordial and nervous electuary is to be given, compofed of the conferves of rofemary, orange-peel, and Roman wormwood, with Venice-treacle, candied nutmeg and candied ginger; of this the bignefs of a nutmeg may be given every morning and afternoon, drinking after it a decoction of piony, mafter-wort, and elecampane, and angelica-roots, the leaves of rue, fage, betony, and other cephalic plants, with orange-peel, and juniper-berries.

Spirit of harts-horn may alfo be given every night in fmall dofes, in a nervous julep, and plafters of gum caranna may be applied to the foles of the feet. According as the cure advances, the patient recovers the ufe of his hand and foot, and his amendment may always be difcovered by letting him attempt to bring a glafs of any liquor to his mouth in a ftrait line; though the bleeding fhould not be repeated beyond the fourth time,

time, yet the alterative and purging medicines ſhould be continued till the patient is quite well; and as people are ſubject to relapſes in this diſorder, it is proper to give the ſame medicines, and to bleed at the return of that ſeaſon of the year.

The firſt ſymptoms in this diſeaſe are often perceived to come on at the hips and os ſacrum, or extremity of the back-bone; from thence a pain extends itſelf acroſs the navel, and thence the pain runs up to the top of the head: as ſoon as this happens the convulſions uſually begin; theſe often firſt appear in the belly, and are ſo violent, that two or three perſons can ſcarce hold the patient, and are forced to lie upon the bed to prevent him from raiſing up his belly in a ſtrange manner.

After this, in ſome caſes, the nerves of the lungs become affected, and the patient will imitate the barking of a dog, or the ſnarling and howling of that animal when hurt: after this, the nerves of the jaws generally ſuffer, and the teeth are ſnapped violently together, and the mouth foams; perſons have ſometimes beaten out their teeth with the violence of ſnapping them together in theſe agonies.

There is, in the Philoſophical Tranſactions, an account of a caſe of this kind following a fever, in which the patient attempted to bite every body about him, and would have even gnawed his own fleſh, if he had not been prevented; but, though the people about him thought, from all theſe ſymptoms, that he had been bitten by a mad dog, and that this was madneſs, yet, on offering him water, he drank, or rather lapped it greedily; which proved it could be no effect of that bite, becauſe the great ſymptom of ſuch diſorders, the dread of liquids, did not ſhew itſelf in him. Theſe were merely the effect of this *Chorea Sancti Viti*, and were attended with twitching of the arms and legs, which conſtitute that diſtemper; his noiſes alſo were not confined to thoſe of a dog, but in different fits, he repreſented the ſounds of different animals, as the roaring of a bull, the grunting of a hog, and the noiſe of a gooſe.

Theſe were not premeditated, or meant by the patient, as imitably of ſuch ſounds, but merely proceeded from the forcing out the air from the lungs in different manners, according to the different power of the convulſion, which affected their nerves. The patient in this caſe was ſpeechleſs, not only in the time of the fits, but for a week together; and the country people fell into the common error of ſuppoſing that he was bewitched, but the phyſician cured them of that belief, by the curing the patient of his diſtemper by the common means, as they were convinced, that a diabolical ſpirit could not be caſt out by a regular courſe of phyſick. Phil. Tranſ. N°. 287. p. 1480.

VIVACE, VIVACEMENTE, or VIVAMENTE, in the Italian muſic, ſignifies to play with life and ſpirit. It requires a degree of movement between *largo* and *allegro*, but neareſt *allegro*. See the articles LARGO and ALLEGRO.

VIVACISSIMO, in the Italian muſic, denotes a degree or two quicker than *Vivace*, and is much the ſame with *allegro*. See the article ALLEGRO.

VIVERRA, in zoology, the name by which authors call the *Ferret*; called by ſome alſo *muſtela ſylveſtris*, *furo*, and *furunculus*.

The uſe we make of this creature, is the ſending it into rabbet holes to drive them out; but we are obliged to faſten up their mouths, that they may not tear the rabbets to pieces; but it ſtill is able to annoy them with its claws, and ſoon drives them out. It feeds on milk, ſmall birds, and the fleſh of animals, and is a creature eaſily kept tame, and will breed and bring up its young in that ſtate; and theſe will naturally hunt the rabbet, in the ſame manner as their parents.

It is of a middle ſize, between the weaſel and polecat; its head is ſmall and flattiſh; its ears ſhort, erect, and very wide; its noſe, or ſnout, long, like that of a hog; and its eyes ſmall and red; its colour is a pale, yellowiſh white; the back and ſides a little darker than the belly; and its feet have all five claws each: it breeds very well with us, but is ſaid not to be a native here, but brought from Africa. *Ray*'s Syn. Quad. p. 198.

VIVERRA *Indica*, the Indian *Ferret*, a name by which ſome have called the animal known in America by the name of *quirpele* and *quil*. See the article QUIRPELE.

VIVES, a name given by our farriers to a diſeaſe of horſes, which conſiſts in the growth of certain flattiſh kernels in cluſters, like bunches of grapes, beginning from the ears, and creeping downwards, between the chap and the neck of the horſe toward the throat.

When they are inflamed they ſwell, and become not only painful to the creature, but are even mortal, ſtopping his wind unleſs a ſpeedy courſe be taken for their cure. The difficulty of breathing, which they occaſion in their progreſs toward this higheſt degree, occaſions many ſymptoms, which being miſunderſtood by the farriers not being well acquainted with the nature of this diſeaſe, are often treated as peculiar diſtempers themſelves, and the creature periſhes by the treatment of them in an improper manner.

The horſe will often lie down, and ſtart up again, and tumble about in a ſtrange manner, and be ſuppoſed to have convulſions, when he has really no other complaint but the difficulty of taking his breath.

The common cauſe of this diſtemper, is the drinking cold water after any violent heat: It is alſo ſometimes ſaid to ariſe from the eating too much bad corn. The method of cure is to be varied according to the progreſs and ſtate of the diſeaſe, and the immediate danger.

If the tumors be not grown ſo large as to put the horſe in abſolute danger of ſuffocation, the farrier uſually attempts to rot them away, by taking hold of each gently with a pair of pincers, and beating them gently with the handle of a ſhoeing-hammer, or bruiſing them with the hand alone, till they grow ſoft; this will often make them diſappear; but this method is only to be uſed when they are nearly ripe; for otherwiſe they will return after a time; their being in a proper ſtate for this, is known by the ſeparation of the hair, which eaſily comes off on the taking hold of it between the fingers. If the caſe be more deſperate, and the horſe likely to be immediately ſuffocated, it is beſt to open them with an inſtrument. Whether this, or the other method be taken, the horſe ſhould immediately after be blooded under the tongue, and afterwards in the flanks, and his mouth waſhed with ſalt and vinegar, and ſome of the ſame mixture ſhould be put into his ears, rubbing and ſqueezing them hard to make it penetrate: this will wonderfully aſſwage the pain. After this, the horſe is to take a quart of white wine, with two handfuls of hempſeed bruiſed, two nutmegs ſcraped, and the yolks of ſix eggs, all thoroughly mixed in it. About an hour after this draught, he is to have the following glyſter: Boil an ounce and half of ſal polycreſtum, finely powdered, in five pints of beer; when this is taken off the fire, two ounces of oil of bays is to be put to it; and the whole is to be thrown up blood-warm. This is a regular method, and ſeldom fails of a cure; but ſome, who are not willing to have ſo much trouble and expence, only cut holes where the kernels are, and pick them out at theſe with a wire; they then fill the hole with ſalt, and at the end of three days it will run; after this they waſh the wound ſome days with the juice of ſage, and heal it with the common green ointment, or with a mixture of honey, butter, and tar.

VIVIPAROUS (*Cycl.*) — The females of all the quadruped claſs are *viviparous*, and thoſe of the bird claſs are all *oviparous*.

The laws of nature in the larger animals, are therefore, in a great meaſure, fixed and certain; but it is not ſo in the inſect tribes, nor in the fiſhes; for of theſe ſome are *viviparous*, and others *oviparous*; and thoſe of genera nearly allied to one another.

Among inſects, the much greater number are *oviparous*; but there are many which are not ſo, as the pucerous, progallinſects, cochineal, &c. The millepedes and ſcorpions are alſo well known to be ſo; all the females of the butterfly, and of ſome other claſſes, lay only eggs; but the moſt ſingular and remarkable inconſtancy in nature, if we may be allowed the expreſſion, is that in the fly kingdom; the ſame claſs of inſects, and even the ſame genus, will furniſh us with ſome which are *viviparous*, and others which are *oviparous*; the two-winged flies give us inſtances of this; but theſe are not ſingle in that reſpect; for among the reptile world, there are other creatures which are ſubject to the ſame varieties; and Swammerdam has obſerved a viviparous ſnail. The two-winged *viviparous* flies bring forth worms, in all reſpects the ſame with thoſe hatched from their eggs in the other ſpecies.

Many authors having obſerved the flies in general to lay eggs, have too haſtily declared flies to be oviparous; and, on the contrary, ſome having ſeen them produce living worms, were of opinion, that they were all *viviparous*. Redi very juſtly blames both ſides for making general inferences from particular facts, and then propoſes a queſtion, whether the ſame fly, in different circumſtances, may not depoſit eggs, or living animals, and whether external cauſes, as the heat of the air, &c. may not make thoſe eggs, naturally ordained to have been laid in that form, hatch in the creature's body, and thence appear in form of a living offspring: but as there is no probability of a chicken being in the body of the hen, though it may eaſily happen that an egg may be detained there, ſo neither is there any probability of that which nature ordained to be produced in the egg ſtate by the fly, ſhould by any accident be made to hatch into a young one, in the body of the mother.

The ſpecies of *viviparous* two-winged flies, are much more rare than the oviparous; and among the four-winged claſs, they are yet more uncommon. It is not certain, that any of the latter, beſide the winged pucerons, are of this kind; but among the former, there are ſix or ſeven ſpecies which are known always to produce living worms, and probably many more will be diſcovered, by a more cloſe attention than has hitherto been given them, to be ſo too. When we ſee the eggs of a fly depoſited in great numbers on food, excrements, or other ſubſtances, it is eaſy to follow the changes of the creature produced from thoſe eggs; and when one has it in the fly ſtate, there is a ſufficient proof that this ſpecies of fly is oviparous: but it is much otherwiſe in reſpect to the *viviparous*

rous kinds; fince when we fee the multitudes of fmall fly-worms already living on any of thefe fubftances, it is not to be known from all their fucceeding changes, whether they were produced from the body of the parent-fly in that ftate, or as eggs.

To diftinguifh with certainty, whether a fly be oviparous or *viviparous*, the beft means is certainly to obferve it in the inftant of its producing its eggs, or young ones, which ever they are; but as that is a moment not eafily feized, its place may be fupplied either by opening the body of a female fly, diftended and full of eggs or young, and the arrangement and form of the bodies contained, will eafily determine the obferver, whether he is to look on them as eggs, or embryo-animals: But a yet more certain way is to take a fly which appears ready to depofit its future progeny, and fqueezing its body, force out in a part of what would naturally have been thrown out in a little time, and it will be eafy to fee whether thefe are eggs or worms.

It is eafy to find about our houfes one of thefe fpecies of *viviparous* flies; the creature is always buzzing about the places where meat is kept, and loves to depofit her young as the common blue flefh-fly does its eggs, on meat. Its way of carrying its wings is the fame with that of the blue fly, and its antennæ are of the fame form. It at leaft equals the blue fly in length, but its body is lefs thick, and is a little bent at the hinder part; its colour is grey. On the corcelet this colour arifes from a feries of long but irregular afh-coloured lines ranged on a brown ground: A fimilar colour is alfo feen on the upper part of the rings of the body; but the grey fpots here are much fhorter than on the corcelet, and almoft fquare, and the colour between thefe is a fhining brown, which, in fome lights, has a caft of blue. Its legs are black; its petty wings whitifh; and its reticular eyes reddifh.

When a female of this fpecies is taken on meat, and has not too flat a body, one may always expect the fuccefs of an attempt to find that fhe is big with living young. Taking a fly of this kind, and in this ftate, between ones fingers, and obferving its hinder part, one fhall ufually fee a fmall and fomewhat cylindric oblong body thruft itfelf out, and move from fide to fide, and fometimes make many finuofities; this will be found to become more and more long, as it is more and more difengaged from the body of the fly, and is indeed no other than a worm now firft appearing, and endeavouring to difengage itfelf from the body of its parent; a few moments now fets it at liberty; and it is no fooner fallen off, than the end of another like worm appears at the fame apperture, and in a few moments gets its liberty, as the former did; this is fucceeded by another, and fo on for ten, twenty, or fometimes many more; and when the creature feems to have done producing them, the flighteft preffure on the belly will fend out numbers more, and fometimes two or three are, by this means, forced out at the paffage together. The aperture is naturally large, through which they are to pafs, and is, befide this, capable of great extenfion.

It is ufually the head of the worm that firft makes its appearance; but this is not always the cafe; and efpecially where external preffure has been ufed, 'tis not uncommon for the hinder part of the worm to appear firft; and when many of them have, by this means, been forced out together, and the paffage by this means is become enlarged, 'tis no uncommon thing for a number of them coming out together, to bring with them a part of the membrane in which they had been enclofed, while in the body of the parent-fly.

The confideration, however, of the many animals of the infect clafs, which are often found to breed and nourifh in their bodies worms, not their own offspring, but that of the eggs of other infects lodged in their flefh, and eating them up alive, might lead one to doubt whether thefe worms, inftead of being the genuine offspring of the fly, were not a fet of cruel enemies which had been long devouring and preying on its entrails; and what might fomething favour this opinion, is, that the fly ufually dies foon after it has finifhed its depofiting them. But there needs no more to refute this error, than to give thefe new-born worms fome meat; the eagernefs with which they bury themfelves in it, is a proof of their being in a condition to eat, and that greedily; whereas the worms bred in the bodies of infects, from the eggs of other creatures, when they leave the body of the creature, have no farther occafion for food, but have nothing to do but to prepare for their transformation. On the other hand, if one continues to obferve thefe worms produced from the fly, one fhall find that they behave in all refpects like thofe produced from the eggs of the blue flefh-flies; they eat the meat to a certain time; then having obtained their full growth, they leave the fubftance they had fed on, and run into the earth, where they are afterwards found in form of nymphs, enclofed in a fhell made of their own fkin; and, at proper diftances of time, there are produced from thefe, flies male and female; the latter, in all refpects perfectly like the parent-fly, from whofe body the worms had been feen to come.

There are, befide this fpecies, two other of the *viviparous* flies, which are not uncommon. Both thefe, in a great meafure, refemble the former; but their bodies are fhorter; and, in the whole, they much more than the other approach to the form of the blue flefh-fly. They are alfo fmaller than the former fpecies; the one of them, however, on the whole, is not much fo, and, though fhorter, yet is much thicker both in the corcelet and body. : They are both, though fmaller than that kind, yet tolerably large flies, and are bigger than the common horfe-fly.

On the leaves of ivy alfo there are often feen, about autumn, two other fpecies of *viviparous* flies, which are eafily diftinguifhed from all the others. Thofe of one of thefe fpecies are larger than the great blue flefh-fly, and have a fhorter and thicker body than that kind. The manner of carrying the wings is alfo the fame in both; but though both have antennæ of the battledore kind, yet they are evidently diftinguifhed by this, that the extremities of the one are lenticular, and thofe of the others prifmatic. Near the origin of each wing thefe have a brownifh fpot, as have thofe oviparous flies which ufually have in their body only two large eggs at a time, and which are produced of the yellow worms, fo common in cow-dung. But thefe *viviparous* ones differ from thofe flies, in that they are larger, and of a deep, but dead brown; whereas the others are black, or nearly fo.

The other fpecies is not much unlike this in form, but is fmaller, being not more than of the bignefs of the blue flefh-fly, and of a bluifh black; fo that it might eafily be miftaken for one of the common flefh-flies, were it not for the two brown fpots at the infertion of the wings; and both this and the former fpecies are plainly diftinguifhed from the cow-dung-fly before defcribed, by their wanting the gold-coloured down which that has on the fore-part of its head. *Reaumur*, Hift. Infect. vol. 4. p. 405. feq.

ULCER (*Cycl.*)—*Callous* Ulcers. The cure of callous *Ulcers* is attended with very great difficulties, and indeed no cure is to be expected, till the callus is perfectly extirpated. This is to be done three ways; the mildeft of thefe, which is fuited to recent callufes, and fuch as are not yet become very hard, is by means of corrofive medicines, and of thefe the milder kinds are often fufficient; burnt alum either rubbed on the parts alone, or applied with an equal part either of the common digeftive or bafilicon, will fometimes anfwer this purpofe in thefe cafes, as will alfo the Ægyptian ointment, to which a fmall quantity of red precipitate may be added occafionally. If the callus will not yield to thefe remedies, it muft be attacked with the common cauftic, or with butter of antimony, or with a folution of quickfilver in fpirit of nitre.

Another mild method of extirpating callofities we are alfo taught by Le Dran. This author advifes to apply, for four or five days, a plafter made of the diachylon with the gums, and the mercurial plafter, with a quadruple proportion of mercury, mixed in equal quantities; this is to be renewed morning and night, in order to foften the callous lips as much as poffible; after this he makes numerous incifions, fo deep as to pafs quite through the fubftance of the callus, and ftops the blood which flows from thefe with dry lint; then the fame plafter is again applied, and fo laid on, that it may touch the naked incifed lips. After about four days of this treatment, the fcarifications are again repeated, and this to a third or fourth time, if the callofity be not before deftroyed.

If callous *Ulcers* are attended with fiftulous finufes, thefe muft always be laid open, before we can attempt to deftroy the callus, with any probability of fuccefs; after this they may be cured as before directed; or, if the ufe of the knife be not fafe, or the patient dreads it too much, it will be proper to form tents, and thruft them up the finus, firft anointing them with the Ægyptian, or with Wurtz's brown ointment. By thefe methods a callus, that is not of long ftanding, may be extirpated; if the ends of the tents, laft mentioned, be touched with butter of antimony, red precipitate, or the infernal ftone, the bufinefs, in that method, will be the more eafily effected; and, in cafes of this kind, where the callus cannot be reached by the corrofive end of the tent, it is a very good method to inject into the finus either the phagedenic-water, or a folution of the Ægyptian or brown ointment in fpirit of wine. The opening of the finus fhould be then clofed, to keep in the injection as long as may be, and the operation frequently repeated.

Sometimes, however, it is found abfolutely neceffary to ufe the knife, as in callous *Ulcers*, or fiftulæ, that are of very long ftanding, and that have formed variety of finufes, and when either nothing can be done by corrofive medicines, or elfe that they tear and corrode the nerves, and bring on convulfions, and other bad fymptoms, before they affect the callus. In thefe cafes the beft and fafeft way is to lay open the finus, taking care not to wound the nerves, tendons, and arteries; and, after that, all the callufes may be eafily deftroyed by the common methods. Finally, if even this method fhould not have the defired effect; and if the patient has a confiderable fhare both of ftrength and courage, and the fituation of the nerves and arteries is favourable, the callus parts muft be all either entirely cut out with the knife, or burned away by the actual cautery. This operation, though a very painful one, is attended with this great good confequence, that it will reduce the moft inveterate callous *Ulcer* to the ftate of a frefh wound; and unlefs a caries, or bad habit of body, or the pox,

scurvy, or dropsy, or some other constitutional complaint, be in the way, it may be cured as easily as a fresh wound. *Heister*'s Surgery," p. 251.

Cutaneous ULCERS. Such of these as attack the skin of the face, both in infants and adults, approach very much to the nature of the truly phagedenic *Ulcers*; for they, like those, arise from an acrimony of the blood, and are very apt to spread abroad.

In both these cases therefore purging medicines, with such as sweeten the blood, will always prove of service. Decoctions of the woods, or of the sharp-pointed dock root, or the herb fumitory, should be drank on these occasions, half a pint at a draught, as hot as can well be borne, three or four times a day. And some of these draughts should be taken in bed, and a gentle sweating be promoted for some time afterwards. And absorbent and sweetening powders; as those prepared from antimony and flower of brimstone, should be taken at the same time. When this case happens to infants at the breast, they can only take some slight doses of medicines to open the bowels; but the mothers or nurses ought to be enjoined the regimen just mentioned.

In regard to the external applications, oil of tartar per deliquium will be found of great service; a pencil or feather is to be dipped in this, and rubbed over the parts three or four times a day. This may either be thus used alone, or else mixed with oil of eggs and wax, and a plaster laid over it, or the de minio, or any other of the lead plasters, or one of sperma ceti and camphor.

If the whole face be affected, which in infants is not unfrequently the case, a plaster would prove highly troublesome; but, in this case, the proper ingredients may be spread in a softer form over a linnen mask. Lime-water is a medicine of great power and value also in these cases, as is likewise the water used in the washing diaphoretic antimony. The *Ulcers* may very properly be washed with either of these, and the litharge or pompholyx ointment afterwards applied; to which, in very stubborn cases, a little crude mercury may be added; and sometimes a small admixture of red precipitate is found necessary; and finally, if these *Ulcers* are attended with a large and foul discharge, it will be proper to sprinkle them with some of the absorbent powders, as tutty, lapis calaminaris, cerus, chalk, or the like, mixed up occasionally with a little native cinnabar, or red precipitate; or, if it be found more convenient, these powders may conveniently enough be made into an ointment with cream. *Heister*'s Surgery, p. 247.

Fistulous ULCERS. When it is discovered, either by the eye or probe, that *Ulcers* are become fistulous, though the fistulæ or sinuses are not yet become callous, the readiest way of curing them is by laying them open, if that can be conveniently done, down to the bottom with the knife, and after this they may be cleansed and healed. As patients, however, are always averse to the knife, the cure of these may be attempted by injecting them with the decoctions of vulnerary herbs, such as agrimony, birth-wort, or ladies mantle, and dressing them with digestive ointments or lint. Many surgeons are, in these cases, fond of thrusting their dressings to the bottom of the sinus with tents; but they are very apt to do mischief by their hardness, and too great length, often bringing on a callus, inflammation, or too great flux of humours on the part. They ought therefore either wholly to be laid aside, in these cases, or else to be made as soft and as short as the nature of the case will admit. The next particular, in the cure of these fistulous sinuses, is to press the fundus as near to the mouth or opening as possible; and when the wound is cleansed, and the proper dressings applied, a small compress, or a slip of plaster, doubled up in the form of a small compress, must be laid on the part where the fundus, or bottom of the fistula, is judged to be seated, securing all on by a larger compress, and the proper bandages. In rolling up, in these cases, the proper method is always to place the beginning of the roller upon the fundus of the fistula, or at least to make the pressure tight upon that part; the continuation of this will urge the contained matter up toward the opening, and the fundus, or bottom of the sinus, will naturally be the first part that heals. When these sinuses penetrate so deep, that there is no coming at their bottoms with the dressings, vulnerary injections must be frequently used; and, of these, none are more serviceable in these cases, than the following: Take of the common digestive, prepared with turpentine, dissolved in the yolk of an egg, an ounce and half; honey, either simple, or the honey of roses, or of celandine, an ounce; common-proof spirit, nine ounces; mix these together for an injection. Or take of a decoction of scordium, or else of southern-wood or agrimony, eight ounces; common-proof spirit, three ounces; elixir proprietatis, or essence of myrrh and aloes, one ounce; honey of roses, two ounces; mix all together. These are to be injected at every dressing, and the opening of the fistula must afterwards be kept closed, to keep them in its cavity for some time, which will much hasten the agglutination of the part. If this method of cure does not succeed, recourse must at last be had to the knife; and, indeed, in very many of these cases, there is no great probability of relief from any other means, particularly where the fundus lies directly downward, or where the fistula takes such an irregular course, that the fundus of it cannot, with any success, be pressed toward the opening. In this case there is no relief to be had, but by laying it open to the bottom. To do this, a grooved probe, or director, should be gently passed down the fistula, and then directing the knife along the groove, the flesh, and common integuments, are to be laid open, as far as is safe and necessary; a free passage is, by this means, given to the corrupted matter, and the part may be come at with the proper dressings. If the opening is attended with a large discharge of blood, as is frequently the case, the wound must be, at the first dressing, filled with dry lint, and afterwards it is to be dressed with the common digestive, with a small mixture of the Ægyptian ointment, or with a little red precipitate, till the wound is perfectly cleansed, and it may then be easily healed in the common way. *Heister*'s Surgery, p. 244.

Putrid ULCERS. When *Ulcers* become putrid or fetid, this accident arises either from a very bad habit of body in the patient, or else from the negligence and unskilfulness of the surgeon.

The acrimony of the blood is by all possible means to be taken off in these cases, and the *Ulcer* to be frequently dressed, and every time thoroughly cleansed. When wounds are dressed but seldom, as will be the case after the sharp engagements in an army, where great numbers have been wounded, it cannot happen, but that the injured parts, in many patients, will be annoyed with heat, putrefaction, and worms.

To prevent and remedy these, the wounds must be dressed with the Ægyptian ointment, mixed with Wurtz's brown ointment, or the phagedenic water may be used with great success, as also red precipitate, either alone, or mixed with burnt alum, or with the common digestive. These applications are to be continued till the fungous flesh separates from the bottom of the *Ulcer*; and while this is doing, it will be very proper to cover the part with lint, dipped in spirit of wine, which is a very powerful remedy against putrefaction.

When the putrid parts are cast off, the cure will be perfected by the common means used in *Ulcers*; and where there are worms bred in the *Ulcer*, no particular cautions need be given against them, since the same applications answer the purpose, whatever resists putrefaction, will also be found to destroy worms. *Ulcers* sometimes prove, however, so very malign and obstinate, that they will give way to none of these remedies; and in these cases, though there be nothing venereal at the bottom, yet the only relief seems from a salivation. *Heister*'s Surgery, p. 248.

Running ULCERS. When stubborn *Ulcers* are attended with a large discharge, there is reason to apprehend that the blood abounds with too large a quantity of a thin acrimonious serum. This cannot be drawn off any way more properly than by cathartic medicines; these and diuretics are to be repeated as often as the strength of the patient will conveniently permit, and he must be particularly cautioned against drinking too freely.

Millepedes, in any form, are very properly prescribed to be taken internally in these cases, as are also the essence of amber, myrrh, balsam of Peru, tincture of salt of tartar, tartarized tincture of antimony, and the like; large and frequent draughts of small liquors are frequently the cause of these disorders, and are therefore most carefully to be avoided; strong ale, or old wine, should be drank sparingly at meals, and nothing between them.

Such meats are best, on these occasions, as have fewest juices in them, and are very well roasted, and the external medicines must be those which have the greatest reputation as dryers.

The principal of these are lime-water, lapis calaminaris, tutty, chalk, mastic, frankinsence, colophony, and native cinnabar; when any of these have been sprinkled in fine powder upon the *Ulcer*, a plaster of diapompholygos, or the like, is to be laid over it. *Heister*'s Surgery, p. 246.

Venereal ULCERS. These are almost always situated either in the groins, after the suppuration of venereal bubo's, or else in the prepuce, frænum, or glans penis, which is usually termed a *chancre*. In females they are frequently situated in the vagina, or labia pudendi, and in either sex sometimes in the nose, palate, lips, fauces, tongue, and uvula; and sometimes the os frontis, and other bones both of the head, and other parts of the body, are subject to them.

The great intention, in these cases, is to expel the venereal poison by proper remedies; for one *Ulcer* of this kind, if neglected or ill-treated, will produce an universal pox. The internal medicines are principally calomel, mixed with purging medicines; and in the intermediate times, decoctions of the woods, with tincture of antimony, and the like; these last are to be taken before rising in the morning, to bring on a gentle sweat, and may be repeated afterwards many times in the day. A strict regimen of diet ought also to be observed; wine, and all vinous or spirituous liquors, are to be forbidden, and all aromatics, spices, salt, and acrimonious or acid things, are poison to persons in these cases: If such a regimen, and a course of these medicines, will not effect a cure, such quantities of mercury must be sent into the blood, as will raise a salivation, by which both the *Ulcers* and the pox, which was the cause of them, will be cured at the same time. When the

 Ulcers

Ulcers are ſituated in the mouth, uvula, fauces, or tongue, the patient ſhould frequently uſe a gargle, made of decoctions of the woods, and ſweetened with honey of roſes, and the *ulcerated* part ſhould be frequently touched with honey of roſes, acidulated with ſpirit of vitriol, and, after this, they may be healed with eſſence of myrrh, amber, or with oil of myrrh made per deliquium.

When the *Ulcers* are on the external parts, they muſt be dreſſed either with the common digeſtive, or with baſilicon, with red precipitate mixed in them; and theſe dreſſings are to be covered, and kept on by a mercurial plaſter; and when they are thoroughly cleanſed, they may be healed in the ordinary way.

Another excellent medicine for cleanſing theſe *Ulcers*, is the phagedenic-water, or, in its place, lime-water, impregnated with calomel; either of theſe may be applied every day many times, and the parts may be, when neceſſary, touched with the cauſtic; and when they are thoroughly cleanſed, they may very ſucceſsfully be healed, either with an ointment made only of crude mercury mixed with turpentine, or with the following: Take of the diapompholygos ointment, and crude mercury, killed with a ſmall quantity of Venice-turpentine, of each equal quantities; mix them in a glaſs mortar into an ointment, or take of the amalgama of lead and tin an ounce, of bole armenic two ounces; mix theſe, and make them into an ointment, by mixing with them a ſufficient quantity of ointment of roſes, or any other ſimple ointment, in a glaſs mortar. If there be at the ſame time a caries of the bone, which is indeed too frequently the caſe, that is to be dreſſed with euphorbium, oil of cloves, phagedenic-water, or ſpirit of nitre with quickſilver diſſolved in it; or, if it can conveniently and ſafely be done, the actual cautery is of ſignal ſervice.

Sometimes, when theſe *Ulcers* fall on a ſoft part of the body, as the groin, they throw out continually ſo large a quantity of lymph, that all the medicines that can be invented or applied, are of no conſequence to ſtop it. This accident is occaſioned either by the rupture or eroſion of ſome of the lymphatic veſſels. In this caſe the ſurgeon ought to try what can be done by proper compreſſes, and a tight bandage; but when theſe, and the other milder applications are of no ſervice, the actual cautery muſt be employed, but with great care and caution to the vitiated parts.

If venereal *Ulcers* of the penis and glans are negligently or unſkilfully treated, an univerſal pox is very frequently the conſequence; the urethra will, in theſe caſes, be often perforated in various places, and the urine will be diſcharged through it, as through a ſieve; and ſometimes the whole glans, or penis itſelf, will be either totally eaten off, or ſo miſerably affected with ſchirruſes and cancers, that the ſurgeon is obliged to extirpate them with a knife. When the noſe is affected by theſe *Ulcers*, it is very frequently entirely demoliſhed by them; ſometimes the palate, with its bones, are ſo eroded and perforated, that an open communication is made between the mouth and noſtrils, and the fluid part of the aliment, in eating, is thrown out by the noſtrils. Theſe paſſages can ſcarce ever be perfectly covered again by fleſh; but when the extremities and edges of them are healed, they may be cloſed with a ſmall plate of ſilver or gold. The tonſils alſo, the external coat of the uvula, and frequently the whole uvula itſelf, are alſo deſtroyed by the virulence of theſe ulcers: And laſtly, the cranium itſelf, particularly the frontal bone, is frequently ſo eroded and perforated by a caries, that the brain lies bare, and the motion of the pulſation of the arteries may plainly be ſeen. 'Tis no wonder if the worſt of ſymptoms, and even death itſelf, follow this, if neglected, or improperly treated. *Heiſter*'s Surgery, p. 249.

ULCERS *of the Head*. See the article HEAD.

ULCERS *in the Leg*. See the article LEG.

ULEX, in botany, the name by which Linnæus calls the plants named by Tournefort and other botaniſts, *geniſta ſpartium*. *Linnæi* Gen. Plant. p. 348. See the article GENISTA *Spartium*.

ULMARIA, *Meadow-Sweet*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, diſpoſed in a circular form. From the cup there ariſes a piſtil, which finally becomes a fruit, compoſed of ſeveral ſmall capſules arranged together in form of a head, each of a crooked ſhape, and each containing one ſmall ſeed.

Mr. Tournefort allows no other ſpecies of this genus, beſide the common *Ulmaria*. *Tourn.* Inſt. p. 265.

ULMUS, the *Elm*, in botany, the name of a genus of trees, the characters of which are theſe: The flower is of the campaniform kind, conſiſting of one leaf, and containing a great number of ſtamina. The piſtil ariſes from the bottom of the flower, and finally becomes a membranaceous or foliaceous fruit, of a heart-like ſhape, in the center of which there is placed a pear-faſhioned capſule, which is alſo of a membranaceous ſtructure, and contains a pear-faſhioned ſeed.

The ſpecies of *Elm*, enumerated by Mr. Tournefort, are theſe: 1. The common *Elm*. 2. The broad and rough-leaved *Elm*. 3. The leſſer *Elm*, with narrow and rough leaves. And 4. The ſmooth-leaved *Elm*. *Tourn.* Inſt. p. 601. See the article ELM.

ULNA (*Cycl.*)—*Cartilages of the* ULNA. The two ſigmoide cavities, in the upper extremity of the *Ulna*, are covered by a cartilage common to both, which is a little interrupted about the middle of the edges of the cavities, by the tranſverſe notches in this part of this bone. The inferior extremity, or ſmaller head of the *Ulna*, is cruſted over by a cartilage round its cylindric border, in the notch near the ſtyloide apophyſis, and for ſome ſpace on the apophyſis itſelf. The cartilage which covers the head of the radius, is alſo ſtretched over the cylindric border thereof, and the lateral portion of the muſcular tuberoſity immediately below the neck, is alſo covered by a thin ſhining cartilage. The lateral half-grooves or channels, at the baſis of this bone, appear likewiſe to be cruſted over with a cartilaginous matter: But this may poſſibly be only from portions of the annular ligaments. *Winſlow*'s Anatomy, p. 140.

ULNARIS *Externus*, (*Cycl.*) a long muſcle, lying on the outſide of the fore-arm, fleſhy toward the os humeri, and tendinous toward the carpus.

It is fixed above to the external condyle of the os humeri, being there united to the anconæus minor, to the annular ligament of the head of the radius, and to the upper half of the external angle of the *Ulna*; from thence it advances and forms a tendon, which paſſes through the external notch, at the lower extremity of this bone, on one ſide of the ſtyloide apophyſis. The tendon, after having paſſed under a particular ligament, ſituated near the os cuneiforme of the carpus, is inſerted in the outſide of the baſis of the fourth metacarpal bone; ſending ſome tendinous filaments to the baſis of the little finger; it is likewiſe often fixed in the baſis of the third metacarpal bone. *Winſlow*'s Anatomy, p. 192.

This muſcle is alſo called *cubitalis externus*, and it is named by Cowper, *extenſor carpi ulnaris*.

ULNARIS *Gracilis*, a muſcle called by ſome, *palmaris longus*. It is a ſmall muſcle, lying between the os humeri and the carpus, on the inſide of the fore arm.

Its body is ſmall and ſlender, and its tendon very long and flat. It is fixed by its fleſhy portion in the ſmall cryſta of the inner condyle of the os humeri, ſometimes cloſely united to the *ulnaris internus*; from thence it runs down fleſhy for ſome ſpace, turning a little obliquely toward the middle of the fore-arm, and ends in a long narrow thin tendon. This tendon paſſes down the middle of the fore-arm, over all the other muſcles, to which it ſlightly adheres, and advancing over the large internal annular or tranſverſe ligament of the carpus, is inſerted in the ſurface thereof, ſending off ſome radiated filaments to the aponeuroſis palmaris. This muſcle is ſometimes fixed to the condyle of the os humeri, by a tendon about a finger's breadth in length, to which the fleſhy body joins toward the middle of the fore-arm. The inferior tendon is alſo ſometimes inſerted in the os ſcaphoides of the carpus, without communicating with the large annular ligament; and ſometimes the aponeuroſis palmaris ariſes from this ligament. From all which variations it may reaſonably be concluded, that that aponeuroſis has no eſſential dependance on this muſcle; and ſometimes this muſcle appears to be only a production from the *ulnaris internus*. *Winſlow*'s Anatomy, p. 193.

ULNARIS *Internus*, a long muſcle, fleſhy at its upper extremity, and tendinous at the other, ſituated on the outer part of the *Ulna*. It is fixed in its upper part, in the backſide of the long or internal condyle of the os humeri, in that part of the olecranium which is next the condyle, along the upper half of the *Ulna* very nearly, and to the middle common tendon of the neighbouring muſcle, commonly termed the *profundus*. It runs in the direction of the external angle of the *Ulna*, and ends by a long tendon in the os piſiforme, or orbiculare of the carpus, reaching likewiſe to the os unciforme, being united to the ligament common to theſe two bones. *Winſlow*'s Anatomy, p. 191.

This muſcle is alſo called *cubitalis internus*, and is named *flexor cubiti ulnaris* by Cowper.

ULOPHONUS, in botany, a name given by the antients to a poiſonous plant, ſince called the *chamæleon thiſtle*, and even at that time known to Dioſcorides, Galen, and others, under the name of the *black chamæleon thiſtle*. The white plant of the ſame name, or the *ixias chamæleon*, ſo called from its yielding a gum like maſtic, but of a viſcous texture while moiſt and freſh, was an eſculent plant.

The antients have taken great care, in all their writings, to expreſs which of the two chamæleon thiſtles they mean, when they uſe the word; but the giving it an abſolutely diſtinct name, or preſerving to it the name chamæleon, and giving to the black kind an appellation wholly different, ſuch as this of *Ulophonus*, mentioned by Pliny, ſeems much better than the diſtinguiſhing them by epithets, which we find, however well underſtood at the time when they were uſed, never proved ſufficient to prevent errors and confuſion in after-writers. See the article IXIAS.

ULPHA, a term uſed by ſome authors to expreſs the muddy ſubſtance which falls off from whetſtones, grindſtones, and the like, which is ſometimes ordered in medicines among the chemical

chemical writers, and is only the communicated particles of the stone, with a very small portion of iron abraded from the things ground on them.

ULPICUM, in botany, a name by which Columella, and some other authors have called the *allium*, or garlick. *Ger.* Emac. Ind. 2.

ULRACH, a name given by some writers to the *sanguis draconis*, or dragon's blood.

ULVA, a name given by some botanical authors to a genus of imperfect plants, consisting of the common oyster-green, the sea-chitterling, and the like, which have been since called by Dillenius, *tremellæ*. See the article TREMELLÆ.

The word *Ulva* is frequent in Latin authors; but its signification has been much controverted. Some have been of opinion that it expressed the Cyprus grasses, others the cat's-tail, and others other particular plants; but it rather seems that the antients used it as a word expressive of all plants that grew by river or water-sides; Pliny, having called the sagitta, or water-arrow-head, one of the *Ulvæ*; and others, having expressed the bur-reed, rushes, and many of the common water plants, very different from one another, by the same name. Bauhine makes the *Ulva* a purple sea-moss allied to the alga. *Dillen.* Hist. Musc. p. 4.

It is supposed by some, that *Ulva* is a name used by the antients for the hop; but it happens only in one author, that is, Cato[a], and there is certainly owing to an error of the press, not to any intention of the author. He mentions the hop as a plant climbing upon the willows, and by its branches affording a good sort of litter for cattle; and this by the name of *Ulva*; but as the word appears in no other author, it is reasonable to suppose, that it is an error of the copists for *upulus*, which was the old name for the hop, the adding of the initial L being only of later times. Pliny, in the same manner, calls the hop *lupus*, by a like error of the transcriber.—[a *Cato* de Re Rust. c. 38.]

ULULA, in zoology, the name of the grey owl, called also *strix cinerea*. It is a very light bird for its size, being very thick covered with feathers, and has a ridged circle of feathers, composed of two rows, round its face. And there is, within this, another greyish circle, composed of slenderer and more distant plumes, which surround the eyes. It is of a mottled colour, mixed of a grey and brown, and is feathered nearly to the feet. It has also several long black streaks on the breast, and the inner circle of the face is variegated with no other colours than brown and white. *Ray's* Ornithol. p. 66.

UMBER (*Cycl.*)—UMBER, or OMBER, in zoology, an English name for a fish of the truttaceous kind, more commonly called the *greyling*, and by the authors in ichthyography, *thymallus*, a fresh-water fish of a very fine taste. *Willughby's* Hist. Pisc. p. 187. See the article THYMALLUS.

UMBER, in natural history, an earth of the ochre kind, used in painting. It is found in Ægypt, Italy, Spain, and Germany; but what we have brought into England is principally from different parts of the Turkish dominions. But it might be found in considerable plenty also in England and Ireland, if properly looked after, several large masses of it having been thrown up in digging on Mendip-hills in Somersetshire, and in the county of Wexford in Ireland.

The characters by which it is known from other earths, are these: It never constitutes a stratum of itself, as the generality of other earths do, but is found sometimes in small lumps among gravel, and other loose matter, and sometimes in the perpendicular fissures of the solid strata. It is of a close compact texture, yet very light, of a smooth surface, and of an elegant pale brown, in different degrees. It is smooth and soft to the touch, and adheres firmly to the tongue, breaks easily between the fingers, and stains at all stains the hands, and makes no fermentation with acids. *Hill's* Hist. of Fossils, p. 63.

UMBILICAL (*Cycl.*)—UMBILICAL *Vein*. Dr. Trew asserts contrary to Casserius, that the *umbilical* vein enters the liver towards the left part of it; and that there is but one *umbilical* vein, which empties itself into the left extremity of the *sinus venæ portarum*, and sends no branches to the liver. See Phil. Trans. N°. 457. Sect. 7.

Dr. Trew endeavours to shew how, after birth, the *umbilical* veins and arteries, separating from the navel, gradually retract within their sheaths, which they have from the peritoneum; and leave the sides of the sheath to grow together, as the sides of the remains of the vessels also do. Hence he infers, that the hæmorrhages, which sometimes happen at the navels of adults, must not be from the *umbilical* vessels, but from some other. Commerc. Norimb. 1737. Hebd. 13 §. 1.

UMBILICUS *Marinus*, a name given to a small oval body of a shelly matter, from its resemblance to the human navel. It is properly the operculum of a shell-fish, serving to close up the aperture of the shell in the buccinum, and other turbinated shells; and to that purpose it is fixed to the anterior extremity of the body of the animal; so that when it retracts its body into the shell, this naturally fills up the mouth of it: it is convex on one side, and flat on the other; the convex side is plain and white; the flat side is yellowish or reddish, and marked with a spiral line.

It is said by authors to have great virtues as an absorbent and astringent; but is not used at present in the shops, though it holds a place in the catalogues of the materia medica, as well of our own as other nations. *Pitisc.*

UMBINUS, among the antients, a kind of coin current in Gallia Narbonensis.

UMBLA, or, as some write it, UMBRA, in zoology, the name of a fish of the truttaceous kind, and nearly allied to the salmon. There are four species of this fish mentioned among naturalists; but the *Umbla prior* and *Umbla altera* of Rondeletius, which are two of them, seem only to be the different sexes of the same fish. These are considerably large, very like the common salmon, but have blue backs and yellow bellies. The third is the fish commonly called the *salvelin*. See the article SALVELIN. And the fourth is the red charre. *Willughby's* Hist. Pisc p. 198. See the article CHARRE.

UMBO, in antiquity, the round protuberant part of a shield. See the article SHIELD, *Cycl.*

UMBRA (*Cycl.*)—UMBRA, in ichthyography, the name of a sea-fish caught in the Mediterranean, and brought to the markets in Italy and other places; called by some *chromis*, and by the Venetians *corvo*.

Its usual size at market is about twelve or fourteen inches in length; but it grows to sixty pound weight, and to the length of five or six feet. It is of a somewhat flatted figure, and its back is ridged, and rises up from the head. It something resembles the carp in its general figure, but is broader. It is very elegantly coloured, for there are a number of long oblique lines covering its whole sides, which are alternately of a fine pale blue, and a beautiful yellow. Its scales are moderately large, and its coverings of the gills, and great part of its very head, as well as its body, are covered with these. Its head is moderately large, but its mouth small, and it has a single beard hanging down from its chin. *Rondelet.* de Pisc. p. 182.

UMBRATILIS *Pugna*, the fighting with ones own shadow. This was one of the kinds of exercise much recommended by the antient physicians; they ordered the persons who used it, not only to box, but wrestle, with his shadow; that is, not only to use his arms, but his legs also; and often to put themselves into a leaping posture, and throw their bodies violently forward, and often to retreat hastily backwards. The custom seems to have been of antient date; Plato expresly mentions it; and St. Paul seems to allude to it in that passage where, glorying in the reality of his conflicts, he says, he does not fight as one who beats the air. The physicians greatly recommended this exercise to people of sedentary lives, and to those who had weak nerves, and were afflicted with tremors. They esteemed it useful also in diseases of the kidneys, and of the thorax.

UMBRINO, in zoology, a name used by some authors for the *coracinus*, or *umbra*, as some call it. The *Umbrino* has by some been esteemed a distinct species of fish from the coracinus; but they seem to differ no other way than as the one is the older, the other the younger fish. *Willughby's* Hist. Pisc. p. 330.

UMBUNCULUS, in natural history, a name given by antient authors to the small prominences in the surface of certain stones. It was originally derived from the word *umbo*, which expresses the prominent knob, or round lump in the center of a shield; and its first use that we find in the naturalists, is, in expressing a very similar thing; that is, the prominent part of the zmilampis. This was a stone of the nature of what we call *oculus beli*, or *bellocchio*, and was of a white ground, and roundish figure, somewhat resembling an eye. It was found in the Euphrates, and other rivers, and had always an *Umbunculus* of a glaucous or bluish colour. This *Umbunculus* was a prominent round spot, such as we see in our *oculi beli*, and and call the *pupil*. It was afterwards used to express the inequalities on the surfaces of flints and agates, which frequently are roundish and obtuse, and represent a kind of umbones.

UMPLE, in our statutes, signifies fine linnen. 3 Ed. 4. c. 5. *Blount.*

UNANNEALED *Bottles*, or BOLOGNA *Bottles*, a kind of *unannealed* glass bottles made at Bologna, and many other places, in the year 1742, which, though appearing very strong, yet are to be broken by a fragment of flint, scarce larger than a grain of sand, thrown into them. Acta Eruditor. 1745. p. 81. See the article *Unannealed* GLASS.

UNAROTA, among the antients, a carriage with only one wheel. *Pitisc.* in voc.

UNCATA, in botany, a name given by some authors to the stramonium or thorn-apple. *Ger.* Emac. Ind. 2.

UNCEASESATH, in our old writers, an obsolete word, used where one killed a thief, and made oath that he did it as he was flying for the fact, and thereupon *parentibus ipsius occisi juret* unceasath, *viz.* that his kindred would not revenge his death; or they swore, that there should be no contention about it. Leg. Ino. c. 37. *Blount.*

Du Cange derives the word from the negative particle *un*, and the Saxon *ceath*; which last signifies the same with *assithment* in the law of Scotland See the article ASSITHMENT.

UNCERTAIN, in the manege. We call a horse *uncertain*, that is naturally restless and turbulent; and is confounded in the manege he is put to; so that he works with trouble and uncertainty.

UNCIFORME *Os*, in the carpus, is the fourth bone in the fecond row; it has its name from the Latin *uncus*, a hook, and is compofed of a body, and a hooked or uniform apophyfis. This apophyfis, which is one of the four eminences on the concave or inner furface of the carpus, is flat, and the hollow fide of its curvature is turned toward the os magnum. The outer furface of its body is rough, and in fome meafure triangular; it compleats the convex fide of the carpus, and, toward the ulna, terminates in a fmall tuberofity, which is all the cubical fide of this bone.

It has three articular or cartilaginous fides, one radial, one brachial, and one digital. The radial fide is double, anfwering to the cubital fide of the os magnum. The brachial fide is very oblique, fome part of it being gently concave, the reft gently convex, anfwering to the digital fide of the os cuneiforme. The digital fide is double, or diftinguifhed into two halves, by a figmoide angular line, for its articulation with the two laft bones of the metacarpus. *Winflow*'s Anatomy, p. 84.

UNCINUS, in furgery, the name of a fmall hooked inftrument ferving to many purpofes.

UNCTUARIUM, a room in the antient baths, where people were anointed before they went away.

UNCTORES, among the Romans, fervants whofe employment it was to anoint their mafter when he bathed. *Pitifc.* Lex. Antiq. in voc.

UNCUS, among the Romans, an inftrument ufed in torturing criminals. It was a kind of club bent and inclined to one fide. *Pitifc.* Lex. Antiq. in voc.

UNDE *Nihil Habet*, a writ of dower. *Blount, Cowel.* See the article DOTE *Unde nihil habet*.

UNDERWOOD, (*Cycl.*)—In the cutting the *Underwood* of coppices, when the ftubs are great, they fhould be ftubbed up, for they only take up a great deal of room, and fend up few fhoots, their cracks and holes letting in water, and ufually half killing them. The taking up thefe fhould be performed in winter, and the fpaces they leave will be foon occupied by young trees, if not, a long branch of fome neighbouring tree may be laid down, and will foon fend up a fufficient fupply of fuckers for the place.

In felling the *Underwood*, it is always proper to leave young trees enough. The worft of thefe may be taken down the next fall, efpecially if any of them grow near a great tree that will be fit to fell the next feafon, becaufe they may be fpoiled by its fall. When trees are at their full growth, there are feveral figns of their decay, as the withering or drying of their top branches; their taking in water at fome of their knots, their being hollow or difcoloured, and their making but fmall fhoots. If wood-peckers make holes in the body, it is a bad fign, and according to the appearance of one or more of thefe fymptoms, it is very proper to cut down the tree before it decays farther. Large and fpreading trees in coppices are often of more mifchief than advantage, as they fpoil a great deal of the *Underwood* by their droppings.

The owner of a coppice muft be very careful when he fells the wood ftanding, by the acre, to mark beforehand what ftandards are to be left, elfe the purchafer feldom fails to cheat him, by felling fome of them. *Mortimer*'s Hufbandry, vol. 2. p. 69.

UNDETERMINED, in mathematics, is fometimes ufed for indeterminate. *Maclaur.* Algeb. p. 298. See the article INDETERMINATE, *Cycl.*

UNDIMIA, in furgery, the name of a kind of an œdematous tumour, the matter contained in which is glutinous and ropy, like the white of an egg.

UNDULAGO, in natural hiftory, a name given by Mr. Lhuyd to a fpecies of fungites found foffile, and ufually of a fort of undulated figure. See the article FUNGITES.

UNDULATED *Leaf*, among botanifts. See the article LEAF.

UNDULATION, (*Cycl.*) in medicine, the term ufed by fome to exprefs an uneafy fenfation in the heart, of an undulatory motion, which may fometimes be perceived externally.

UNDULATION is alfo a word ufed by fome authors to exprefs the rifing of the water of the furface of the fea into waves. See the article WAVE.

UNDY, in heraldry. See the article WAVED, *Cycl.* and *Suppl.*

UNEDO, in natural hiftory, a name ufed by the antients for a fruit which they recommend as cooling and fub-aftringent. The generality of the world are lead into a common error of believing this to be the fruit of the arbutus or ftrawberry-tree. Pliny has given occafion to this error, by faying exprefsly that the *Unedo* is the fruit of the arbutus; but we find this to be contrary to the practice of all the antient Latin writers, who have always called the fruit by the fame name with the tree, not by a different one. Varro de re Ruftica, fpeaking of gathering the autumn fruits, calls them all by the name of the trees; and among them, mentioning the fruit of the arbutus, he expreffes it in the fame manner, not by the word *Unedo*, *decerpendo arbutum mora pomaque*: And both Galen and Paulus Ægineta deny the *Unedo* to be the name of the fruit of the arbutus or ftrawberry-tree, and make it the fruit of the epimelis. Servius explains the word *Unedo* by the fruit of the ftrawberry-tree; but in this he too rafhly follows Pliny's opinion, and plainly errs from the truth. See the article EPIMELIS.

UNGUENT (*Cycl.*)—UNGUENTUM *Album*, the white ointment, a medicinal preparation, well known by name, and much ufed in families.

The late London difpenfatory has made very great alterations in it, and indeed given a new ointment under this name; it is there ordered to be made thus: Take oil-olive a pint, white wax four ounces, fperma ceti three ounces, melt all together with a gentle heat, and ftir them very brifkly without ceafing, till they are fully cold.

The ointment, formerly known by this name, had cerufs, or white lead, for its principal ingredient; but as this is principally intended for frettings of the fkin, that ingredient was judged dangerous. *Pemberton*'s Lond. Difp. p. 363.

UNGUENTUM *Bafilicum Viride*, a form of medicine prefcribed in the late London pharmacopœia. It is ordered to be made thus: Take of yellow bafilicon eight ounces, oil of olives three ounces, verdegreafe in fine powder one ounce, mix the whole into an ointment. *Pemberton*'s London Difp p. 366.

UNGUENTUM *Nardinum*. See the article NARDINUM *Unguentum*.

UNGUENTUM *e Pice*, *Tar Ointment*, a form of medicine prefcribed in the late London Pharmacopœia, and ordered to be made in the following manner: Take of tar, and of tried mutton-fewet, each equal quantities, melt them together, and and ftrain the whole while it is hot. *Pemberton*'s Lond. Difp. p. 368.

UNGUENTUM *Saturninum*, a form of medicine prefcribed in the late London Pharmacopœia, and ordered to be made in this manner: Take of oil-olive half a pint, white wax an ounce and half, fugar of lead, firft brought to a very fubtile powd r, with fome part of the oil; then add this to the reft of the oil, with the wax melted in it, and ftir the whole till it is cold. *Pemberton*'s Lond. Difp. p. 369.

UNGUENTUM *Simplex*, a name given in the London Difpenfatory, to the compofition commonly called *pomatum*; the manner of making which, is according to the method now univerfally practifed, delivered there in the following manner: Take of tried hogs-lard two pounds, of rofe-water three ounces; pound the lard with the rofe-water, till they are well mixed; then melt the lard with a very gentle fire, and fet it by awhile, that the water may fubfide, afterwards pour out the lard, and leave the water; then ftir and beat the lard without ceafing, while it is growing cold, that it may be broke into as light and yielding a mafs as may be; and then add as much effence of lemons as will give it an agreeable fcent. *Pemberton*'s London Difp. p. 362.

UNGUENTUM *e Sulphure*, *Sulphur-Ointment*. Take of fimple ointment half a pound, of flower of fulphur unwafhed two ounces, effence of lemons a fcruple. This is the preparation ordered in the late London Difpenfatory, and expected to be kept ready mixed in the fhops. *Pemberton*'s London Difp. p. 370.

UNGUENTUM *Veficatorium*, *Bliftering Ointment*, a form of medicine prefcribed in the late London Pharmacopœia, and no other than bliftering plafter in a fofter form. It is made by equal quantities of hogs-lard and blifter-plafter, with a very gentle heat, ftirring them till they are cold. *Pemberton*'s Lond. Difp. p. 371.

UNGUENTUM *Viride*, the *Green Ointment*, a form of medicine prefcribed in the late London Pharmacopœia, and ordered to be made by melting ten ounces of yellow wax in three pounds of the *oleum viride*, or green-oil, of the fame pharmacopœia. *Pemberton*'s Lond. Difp. p. 371.

UNGUICULI, in botany, is ufed for the ends of the petals of rofes, or other flowers, where they adhere to the plant.

UNGUIN, in botany, a name given by the people of Guinea to a plant, of which they are very fond, for its medicinal virtues: They boil it in water, and give the decoction in large draughts for pains in the back. The leaves of this plant grow alternately on pedicles of an inch long, and have the exact fhape and fize of thofe of the common bay-tree; but they have neither its tafte nor fmell, nor any thing approaching to either. Phil. Tranf. N°. 232.

UNGUIS (*Cycl.*)—The nails both of the fingers and toes are fubject to very great diftemperatures in their growth. We have, in the Philofophical Tranfactions, an account of a young fellow, whofe finger ends were, as it were, armed with horns inftead of nails; they grew to a very amazing length, but then would wear away, or drop off at the ends. The horny excrefcence on the thumb was the longeft on each hand, and next to it was that of the middle finger, the reft being gradually fhorter; his feet were well armed with the fame fort of weapons, only that the two little toes had none of them.

Thefe horns feemed to owe their origin to a thickening of the body of the nails, which, inftead of growing out in length in the common way, elevated themfelves in height from the back; and when they had rifen to a certain height in this direction, they turned downward, and became crooked, fo as to reprefent a bird's claw, only that it was not taper and fharp, but all of the fame thicknefs, and blunt at the end. The upper or convex part of each was marked with a great many chaps, but the concave or under part was fmooth. The

The lad had no fenfe in thofe parts of the horns which were at a diftance from his fingers; but they might be cut or pulled any way, without giving him pain; when they were moved near the roots, where they joined the finger, the pain was very great. The back of his hand was full of horny fubftances, of a like texture with thefe, but not elevated above the fkin; they had the appearance of broad and flat warts, but were much larger and harder. The difeafe feized the lad after the fmall-pox. The common length of thefe horns on his fingers was between three and five inches. Phil. Tranf. N°. 229.

UNGUIS *Odoratus*, in the materia medica, a thin flat teftaceous fubftance, of an oval or oblong figure; rounded at both ends, and marked on the furface with three or four concentric circles, or oval lines. Its colour is a dufky brown, with fome admixture of the orange, fometimes of a purplifh tinge. Its ufual fize is that of a full grown nail of a man's thumb; and its thicknefs rather lefs than that of the nail. It is tough, flexile, and elaftic; and has no peculiar fmell or tafte.

The want of fmell might feem to argue this to be a different fubftance from the *Unguis odoratus* of the antients; but the truth is, that theirs owed all its fweet flavour to its being brought over among aromatic drugs.

There were two kinds of it, the largeft of which they had from the red-fea, and the other from Babylon; and both were the opercula of two fpecies of murex-fhells. See the article MUREX.

Diofcorides tells us that this *Unguis* was the operculum or poma of the fhell, which ftopped the mouth at pleafure, and from under which the creature thruft out its tongue to feed; and he adds, that the fhell-fifh to which it belonged was taken in the marfhes of India, when the waters were dried away; and that the Indian fpikenard growing in great abundance in thefe marfhes, the creature became fweet-fcented in every part, by feeding on it. But in the latter part of his account he feems to forget the beginning; for he concludes with telling us, that there were only two kinds brought into Greece in his time, the one from the Red Sea, the other from Babylon.

The truth is, that fpikenard grows neither in the Red Sea, nor any where about Babylon, but only in India beyond the Ganges, or about its banks. The fpikenard alfo does not grow in the water, but only in marfhy places, and therefore can never be in the way of feeding fhell-fifh. Nay, this very author, in his defcription of the fpikenard, tells us, that it grows on mountains, and that the fpikenard which grows in wet places, is another kind, and not the fine aromatic fpikenard fo valued in the fhops; even the laft kind, however, could not ferve for the feeding the fifh neither; for he fays, that it grows in wet or moift grounds, but not in the water.

From this, and fome other fuch paffages, it appears that Diofcorides was an author too much of Pliny's ftamp, and collected his accounts of things from different authors, and that without a fufficient knowledge of the fubject; fo that he often contradicts himfelf. As to the Indian fpikenard, Garcias tells us, that it is not produced wild, but is a cultivated plant, raifed by fowing the feeds in gardens, not under water. Avifenna feems to have feen this abfurdity in Diofcorides, about the fhell-fifh feeding under water on the fpikenard, and though he tranflates the account of his *Unguis odoratus*, or *adfer althaib*, *verbatim* from Diofcorides in other parts, yet he here alters the fenfe, and fays, that the fhell-fifh was found in an ifland in the Indies, on which ifland the fpikenard alfo grew in great abundance.

This, however, is but avoiding one error by another; for though, by this, he gets over the abfurdity of the fpikenard's growing under water; yet he falls into a much worfe, which is, of the fhell-fifh to which the *Unguis odoratus* belongs, being found on dry land.

It is very certain that no fhell-fifh, living in the water, can fubfift, without fome means of clofing up its cavity, fo as to keep out the water at pleafure; this is done in the bivalve kinds, by clofing the two valves; but in the ftromboide ones, by drawing down this operculum, which is the *Unguis odoratus*, to the mouth of the fhell. A land-fhell therefore can have no occafion for fuch a part as the poma or operculum, and no fuch drug as the *Unguis odoratus* can be found about it. But it is to be obferved, that Avifenna did not know that the *Unguis odoratus* was a covering or operculum of the mouth of a fhell, but thought that it was only a fragment cut or broken indeterminately from any part of the fhell. This therefore might appear no abfurdity to him, and the thin and flat *Ungues* he faw might appear fragments artificially cut from fome of the thin-fhelled kind of land fnails.

UNGUIS *Offa*, in anatomy, are two bones which help to compleat the internal fides of the orbit of the eye, to cover the fore-part of the labyrinth of the nofe, and form the lachrymal duct.

They have their name from the Latin *Unguis*, a nail of the hand, and are alfo, by fome authors, from their office in forming the lachrymal duct, called *offa lachrymalia*.

They are each fituated in the orbit of the lower part of the internal angle; they are the leaft bones of the face, and are very thin and tranfparent. They are in fhape fomewhat longer than broad, and not unaptly refemble the figure of the finger nails, efpecially while in their natural places; for, being taken out of the fhell, their figure becomes fomewhat more irregular. Each of them is divided, by anatomifts, into two fides, the one external, the greateft part of which appears in the orbit in an entire fkull; the other internal, which is hid; two extremities, the one upper, the other lower; and two edges, one anterior, the other pofterior. The outfide is fmooth, and a little concave; toward the anterior edge is a groove full of fmall holes like a fieve, called the lachrymal groove. It begins at the upper extremity, and runs down lower on this fide than any other part of the bone, the lower extremity of it being hid by the os maxillare. It is diftinguifhed from the reft of the outfide by a very fharp prominent edge. The infide is rough and unequally convex, with a perpendicular depreffion anfwering to the fharp prominence on the outfide. On the upper part of this infide, fmall portions of cellulous laminæ are fometimes obfervable, which communicate with the entry of the frontal finus; and there are likewife fome about the middle, which compleat the anterior ethmoidal cells; and others toward the lower end, which communicate with the rugged portions of the upper border of the finus maxillaris: thefe, however, often vary, and are fometimes wanting.

Thefe bones are altogether without diploe; they are connected with the os frontis, and with the os ethmoides, covering a part of the cells in that bone, with the nafal apophyfes of the os maxillare, and with the groove of that bone in fuch a manner, that the two grooves, joined together, form an entire tube, called the lachrymal duct; they alfo cover a little the opening of the maxillary finufes, and join the inferior conchæ of the nares, of which they appear to be only a continuation in advanced age. *Winflow*'s Anatomy, p. 36.

UNGUIS *of a Flower*, among botanifts. See the article PETAL.

UNGUIS, in natural hiftory, a name given by authors to a genus of fhells, called more ufually *folenes*. See the article SOLEN.

UNGULA *Oculi*, the name given by fome to a difeafe of the eye, called by others *pterygion*.

UNGULUS, in antiquity, a remarkable kind of bracelet. *Hofm.* in voc. See the article BRACELET.

UNHALTER, in the manege. A horfe is faid to *unhalter* himfelf, that turns off his halter. See the article HALTER.

UNICORN (*Cycl.*)—*Sea* UNICORN, in natural hiftory, the name of a fifh of the whale kind, remarkable for having a horn growing out at its nofe, in the manner of the fuppofed *Unicorn*'s horn, as defcribed by many too credulous authors.

This fifh feeds on flefh, or other fifh, and is not only found in the main fea, but fometimes gets up into large rivers. In the year 1636 there was a large one caught in the river Ofte, near its difcharging itfelf into the Elbe, in the duchy of Bremen; this place is four German miles from the fea. The fkin of this fifh was fpotted with dark brown fpots upon a white ground, the epidermis was tranfparent, and under it was another fkin very thin and fpotted; but the true fkin was brown, and near an inch in thicknefs. On the top of the head there is only a femilunar hole, as in the porpoifes; this hole opens into the two channels, which run through the fkull to the palate, and are called the ductus hydrogogi. The people who examined this creature, were not able to find any aperture in the body for the difcharge of the excrements; whence it has been generally believed, that the creature voids them through this paffage in the head.

Authors have differed in the name of the procefs iffuing from the head, fome calling it a horn, others a tooth; fome are of opinion that it ferves it to break the ice with for air; but others pretend that it is an offenfive weapon, with which it wounds the common whale, and other large fifh; and that when it has plunged it up to the head in the whale's body, it fucks the juices of that animal. See Tab. of Fifhes, N°. 1.

The fifh was near twenty foot long, and about four foot in diameter. The horn ftood on the fore-part of the head, juft above the mouth, and was fix foot long, white like ivory, and curioufly wreathed or twifted. The body was fmooth and flippery, like that of an eel; the head, in proportion to the body, was fmall, not exceeding fixteen inches in length; the eyes not larger than a fix-pence. It had, on each fide of the neck, two black fins, one above, another at a fmall diftance; thefe were two foot long, of the breadth of a hand, and about half an inch in thicknefs. Phil. Tranf. N°. 447. p. 149.

Unicorn's horn has been fo common in the Danifh and neighbouring feas, that there was a magnificent throne built only of them in that kingdom; the horns are from ten to fifteen foot in length, and are all white, and furrowed with a fpiral line. They are the horns of that kind of whale called *narwal*, or the fea-*Unicorn*. *Brown*'s Travels.

Unicorn's horn has the fame medicinal virtues with hart's-horn and ivory; but at prefent is only kept as an ornament to druggift's fhops.

Sea-UNICORN is alfo a name given to two forts of fmall fifhes caught in the American feas, and known among authors under the name of *monoceros pifcis*. See the article MONOCEROS.

UNICORNU *Foffile*, *Foffile Unicorn's Horn*, the name of a fubftance much ufed in medicine in fome parts of the world, but which feems to have been very little underftood by many who have written of it. Dr. Hill, from the examination of the

ſeveral varieties of ſhapes it is found in, and trying it by the ſeveral teſts which fix the criterions of foſſils, has determined it to be no other than a terrene cruſtaceous ſpar, not very different from the oſteocolla, and other bodies of that genus, which he has called the *cibdeloplacia*; and has diſtinguiſhed this peculiar ſpecies by the name *cibdeloplacium albido-ſubcineteum, friabile ſuperficie lævi*, or the whitiſh-grey friable cruſtaceous ſpar, with a ſmooth ſurface.

It differs principally from the oſteocolla in its ſoftneſs and the ſmoothneſs of its ſurface; but from its having, like many other of the cruſtaceous terrene ſpars, the property of encruſting, and ſometimes even permeating the pores of bodies, and in a manner petrifying them, it has obtained the names of the things it thus lodges itſelf in and about, which being uſually bone, and ſome of them bones of an extraordinary ſize and figure, have been taken for the bones and horns of *Unicorns*; and the name and nature of the body itſelf wholly loſt and neglected, and that of the horn, with that of its imaginary animal, only preſerved.

They are, however, now ſenſible in Germany, that it is not the horn, but this ſubſtance which is lodged about it, which is the medicine; for they never uſe the foſſile bones, which are petrified in the common way, but only ſuch as are impregnated with this ſparry ſubſtance; and even uſe all ſubſtances whatever, which are impregnated with this, whether bones or wood, under the ſame name, calling the natural tubular pieces of it, which are very common, and alſo the pieces of branches of tree impregnated with it, by the common name of *Unicorn's horn*, while they allow plain bones, petrified in the common way, no ſuch name. So that the word is now become a mere technical term, and ſignifies either this ſpar in its pure ſtate, or any ſubſtance whatever which is impregnated with it.

It is a lax and ſpongy terrene ſpar, and is naturally of a regular form, in ſome degree like that of the oſteocolla, being always found, where it has concreted pure and not been in the way of any extraneous ſubſtance, an oblong and moderately thick cylindric tubular body, frequently narrower at one end than the other, and approaching to a conic form. Uſually its hollow is empty, but ſometimes it is found filled up with a ſubſtance of the ſame nature with itſelf, only compoſed of a larger proportion of earth with leſs ſpar, and therefore more crumbly and ſoft. Theſe are found of various ſizes, from an inch to three feet long. The larger ſpecimens are moſt frequent. And it is very probable, that the ignorance of the firſt ages, which brought it into uſe in medicine, might take theſe natural concretions for *Unicorns horns*.

It is found in other parts of the world beſide Germany, and is in great eſteem in many places as a ſudorific and aſtringent; and is given in fevers, attended with diarrhœas, with great ſucceſs. *Hill's* Hiſt. of Foſſ. p. 361.

UNIFORM (*Cycl.*)—UNIFORM *Matter*, in natural philoſophy, that which is all of the ſame kind and texture.

UNILOCULAR *Capſule*, among botaniſts. See the article CAPSULE.

UNISETA, in natural hiſtory, the name of a ſpecies of fly, found frequently ſitting on the ammi or biſhops-weed, and inguiſhed by having one long hair or briſtle growing out at its tail. See the article HENOTHRIX.

UNITE, in the manege. A horſe is ſaid to *unite*, or walk in union, when, in galloping, the hind quarters follow and keep time with the fore. See the article SINEW.

UNITY (*Cycl.*)—It is to be obſerved in algebra, that *Unity* itſelf has three different expreſſions of its cube root, one real, and the other two impoſſible or imaginary. Thus the three cube roots of 1, are 1, $\frac{-1+\sqrt{-3}}{2}$ and $\frac{-1-\sqrt{-3}}{2}$.

This is ſometimes of uſe in finding the cube roots of quantities, appearing under impoſſible expreſſions. See *Maclaurin's* Algebra, p. 128. ſeq.

The two impoſſible expreſſions of $\sqrt[3]{1}$ may be thus found: Let $x=1$ then $x^3=1$ or $x^3-1=0$ and $x-1=0$. Divide x^3-1 by $x-1$ the quotient is $xx+x+1=0$. Or $xx+x=-1$ reſolve this quadratic equation, by adding $\frac{1}{4}$ to both ſides. Then $xx+x+\frac{1}{4}=-\frac{3}{4}$, and extracting the ſquare root, $x+\frac{1}{2}=\sqrt{-\frac{3}{4}}=\frac{\sqrt{-3}}{2}$. Therefore $x=-\frac{1}{2}\pm\sqrt{-\frac{3}{4}}=\frac{-1\pm\sqrt{-3}}{2}$. That is, $x=\frac{-1+\sqrt{-3}}{2}$ and $x=\frac{-1-\sqrt{-3}}{2}$. See *Maclaurin*, lib. cit. p. 226.

UNIVALVE *Shells*, in natural hiſtory, a term uſed to expreſs one of the three general claſſes of ſhell-fiſh; the other two are the bivalves and multivalves. The *univalve* ſhells are thoſe which conſiſt only of one piece, not of two or more joined together. Of theſe *univalve* ſhells, nature affords a very great variety; ſo that they are aptly diſtributed by a late French author into fifteen diſtinct genera. Theſe are, 1. The *patellæ*, or limpets. 2. The *patellæ planæ*, called alſo *auris marina*, the ear-ſhell. 3. The *canales*, or *tubuli marini*, the ſea-tubes. 4. The lunar cochleæ, or round-mouthed ſnails. 5. The *cochleæ ſemilunares*, or ſnails with ſemicircular mouths. 6. The *cochleæ ore depreſſo*, or flat-mouthed ſnails. 7. The *naviculæ* or boat-ſhells, commonly called *nautili* or *nautilus*. 8. The *buccina*, or trumpet-ſhells. 9. The *turbines*. 10. The *volutæ*. 11. The *rhombi*. 12. The *murices*. 13. The *purpuræ*. 14. The *conchæ globoſæ*. And 15. The *porcellanæ*, each of which ſee under its proper head, PATELLA, AURIS *Marina*, &c. Hiſt. Nat. Eclairc. part 2. p. 235.

UNIVERSAL (*Cycl.*)—UNIVERSAL *Equinoctial Dial*. See the article RING-*Dial*, *Cycl*.

UNIVERSAL *Problem*. See the article INDETERMINED *Problem*, *Cycl*.

UN POCO, in the Italian muſic, is often put before the terms *allegro*, *adagio*, *preſto*, *piano*, &c. Where it ſhews that the movement, with their direction, is ſomething leſs than it would otherwiſe have been, had this word been omitted. Thus *allegro* ſhews that the movement is to be made in a briſk and gay manner; and *Un poco allegro* the ſame, only in an inferior degree, and ſo of the reſt.

But if *piu* is put between *Un poco*, and the above-mentioned terms, then their uſual ſignification is a little increaſed, as *Un poco piu allegro* ſignifies a little more briſkly than *allegro* alone requires. The contrary of this happens if, inſtead of *piu*, the word *men*, or *meno*, be uſed, as *Un poco meno allegro*, i. e. a little leſs gayly than if *allegro* were alone. See the articles ALLEGRO, ADAGIO, PRESTO, &c.

VOARCHADUMIA, a kind of cabala, or ænigmatic art, relative to metals, which propoſes the exultation of gold by cementations, and other methods; among which charms made of the Hebrew letters have their place.

VOCA, in ichthyology, a name given by Gaza, and ſome other writers, to the fiſh called *boops* by the generality of writers. It is a ſpecies of the ſpari, and is diſtinguiſhed from the reſt by having four longitudinal parallel lines, of a bright yellow and white colour, reſembling gold and ſilver on its ſides. See the article SPARUS.

VOCATORES, among the Romans, were ſervants whoſe buſineſs it was to call the gueſts, receive them, and aſſign every one a place according to his dignity. *Pitiſc.* in voc.

VOCE *Sola*, in the Italian muſic, denotes a piece compoſed for a ſingle voice, generally accompanied with a thorough baſs on the harpſichord or organ, without other inſtruments. But if beſides that it is to be accompanied by other inſtruments, they add, *con violini*, with violins; *due violini*, *e violoncello*, *e baſſo per l'organo*, i. e. with two violins, a baſs violin, and a thorough baſs on the organ; *con violini o ſtromenti*, i. e. with violins, or inſtruments; *parti*, *con parti ſenza violini*, i. e. part with, part without violins, &c.

VIOLATICA, in medicine, a name given by authors to a ſort of wandering pain, attended with a tumor, and affecting, at different times, different parts of the body; it is by ſome accounted a ſpecies of the ſcurvy; by others, of the leproſy.

VOLATILE *Salts*. It is the opinion of many of the greateſt chemiſts, that our diſtinction of ſalts into fixed and *volatile*, is far from juſt, for that there are in nature no ſuch thing as fixed ſalts.

Tartar is generally allowed to contain as much fixed ſalt as any thing, yet this ſubſtance, treated by fermentation, in Langelot's method, yields all in *volatile* ſalt that it would otherwiſe have yielded in fixed, and leaves ſcarce any fixt at all. The ſame proceſs will have the ſame effect on the ſuppoſed fixed ſalts of moſt other ſubſtances; and upon this, and many other conſiderations, it appears highly probable, that our diviſion of ſalts into fixed and *volatile* is unknown to nature; there not being to be formally found in any body, before calcination, any fixed ſalt; but ſalts are in themſelves all *volatile*, though by the action of the fire they are apt to be colliquated among themſelves, and blended with the earthy parts, and by that means rendered fixed.

The diviſion of ſalts into acids and alkalis has much more reaſon for its foundation: Theſe are differences which really exiſt in them, and by means of theſe all fermentations, and all motions in natural things begin. Both theſe ſalts appear to be in their own nature volatile, and therefore eaſily reſoluble by the ſupervening ſalt of the air.

It appears that all vegetables, eſpecially the aromatic claſs, if they are any conſiderable time expoſed to the air, loſe their ſalts. The soundeſt wood, loſing its ſalts in proceſs of time, in the ſame manner moulders away.

Theſe are proofs that the ſalts of theſe bodies are in themſelves volatile, though they are all liable to be rendered fixed by the action of fire, by which means the acid and the alkali are blended together, and the mixture becomes fixed.

There is an old axiom among the chemiſts, that things volatile are rendered fixed by ſuch things as are fixed; and thoſe fixed are rendered volatile by ſuch as are volatile; but it appears from theſe proceſſes, when rightly underſtood, that this is an erroneous maxim, that two volatile things may fix one another; and two fixed things may become volatile together, according to the nature of the proceſſes by which they are treated. The common traders in timber are well acquainted with theſe properties of the ſalts of wood, though they know not the reaſons of them; and as the air or fire may alter or drive off the ſalts of timber, and ſo render it leſs firm and ſtrong, they ſink ſuch pieces under water as they would

preserve a long time. When they are to place the ends of posts in the ground, they, on the same principle, burn them a little, that the volatile salts, which would easily be consumed by the moisture of the earth, may be, in some degree, liquated and blended together by the heat, and be rendered so much the more fixed, as to be less easily affected by external accidents. Ship-builders, in some places, for the same reason, burn slightly all the timber that is to make the bottom of the vessel, or such part of it as is to be under water.

Another very familiar instance of the blending the two *volatile* salts, naturally given to all vegetables, is in the formation of soot. When wood is burning, there ascends from it a smoak; in this smoak the two *volatile* salts of the wood are contained, and they coagulate one another into that body which we call soot, and from which they may be again separated by art, and rendered visible distinctly. These salts continue ascending, and forming soot, till the wood is reduced to ashes; and what remain of them toward this conclusion of the operation of the fire, are blended together by it, and make what we call the common fixed alkali, a salt easily washed out by water.

The formation of the fixed salt being thus owing to the mixing together of the two *volatile* ones found in the plant, it is easy to conceive why we obtain more of it from sound wood, than from such as is rotten, and more from fresh plants, than from such as have been dried. If the fixed salt existed as a fixed body in the vegetable, it could not be affected by the evaporation of the water in drying, or by the evaporating of whatever else evaporates in the decaying of wood. But as the salt itself, or its two constituent parts, though called fixed by us, and rendered so by fire, are really *volatile* while in the plants, it is no wonder that, being resoluble by the salt of the air, they are carried off in the drying, and much more so in the decaying of wood; for the air, in this case, evidently penetrates all its parts; and hence it is, that as dry plants yield less fixed salt than fresh ones, so the same wood, which, while sound, would have yielded a very large quantity of salt, yet being rotten, yields scarce any at all, though the same process is observed in burning it.

We are indebted to the pains of Dr. Cox for a method of procuring a *volatile* salt from plants, a thing of considerable use in medicine, though so much out of the common road of the chemical analysises that it was not discovered till about eighty years ago, and soon after reduced to practice, in a regular manner, by that physician.

The method is this: A quantity of the leaves of any plant are to be carefully stripped from the stalks in summer, in dry weather; lay them in a heap, pressed hard together, and they will soon ferment and heat, and will be reduced to a pulpy substance. This is to be rolled into little balls, and put into a retort, and distilled; it will yield a thick liquor, of a strong smell, and a large quantity of a black oil, of a balsamic consistence. The liquor is to be separated from the oil, and distilled over again in a tall glass cucurbit; a *volatile* spirit arises; this is to be rectified two or three times more, and then is not to be distinguished from the spirit of harts-horn, urine, or other animal substances, by any trials. Philos. Trans. N°. 101. p. 4.

All plants that have ever been tried in this manner, yield this *volatile* salt dissolved into the form of a spirit; and the very lowest class of plants, the mosses, and common grass, yield it as well as any other. And it is remarkable, that the vessels in which these operations are performed, have afterwards a smell like musk, which all the cleansing in the world, and even the exposing them to the air, does not well clear them of. The caput mortuum left in the vessels is much less in quantity than in the common distillations of a like quantity of the same plant; and if the plants have not been sufficiently fermented before the distillation, there remains, after the first rectification of the spirituous liquor, a sour water.

The *volatile* salt, thus obtained, is considerably more in quantity than the essential or the incinerated salt would have been in the common ways of preparing them; but those plants which yield most fixed salt, always yield most *volatile* salt this way. And these volatile salts, when well rectified, do not differ from one another, though made from ever so different plants; but this is not wonderful, since the fixed salts also, and the vinous spirits of all plants are alike, when reduced to the same degree of perfection and purity. The herb, as it ferments, affords its natural smell at first very strongly; after that it yields a mixed smell, between its own natural scent and an urinous one; and at the end, when it is nearly ready for distillation, the smell becomes urinous. In this operation, the urinous spirit and salt come over chiefly toward the end of the distillation, and are seen in form of white clouds, issuing very fast out of the neck of the retort, and condensing on the sides of the receiver into little rivulets, or winding streams of water.

Sage, winter savory, and some other of the aromatic plants, yield thin *volatile* salt, on the first distillation, in a dry form, coating over the inside of the receiver on the upper part, and clogging the neck of the retort; and saffron, in digestion with spirit of wine, has been found to yield its salt in the same dry form.

The oils procured in this manner from fermented plants partake nothing of the nature of the peculiar plant, but are alike from all; they are thick as tar, and foetid. If the plant be not well fermented, indeed, the oil will be clear, and leave the smell and virtues of the plants: But this is an error in the process, and this oil comes at first; whereas the proper oil of this process comes not till the last, with the salt. Those plants which, in the common way of distillation, yield most essential oil, yield also most of this black thick oil in this process.

The fatty, moist, and insipid herbs, ferment much quicker than the other kinds: They become extremely hot in this fermentation, and lose their peculiar qualities in it; the spurge loses its milkyness, and the celandine its tinging quality; and the juices of those which are naturally the most acrid and sharp, become little more so than those of others. The stinking plants, such as the atriplex olida, are as sweet in this process as any other; and it is particular, that the monk's rhubard, and some others, which are as inodorous as any plant can be, in their natural state, are as foetid as human excrements, under this treatment: And it is remarkable, that the very greatest heat of the fermentation of these plants, does not prevent their being stored with a sort of maggots, which swarm in great numbers in those parts of the fermented mass, where the heat is so great, that a person cannot bear his hand in it.

It is to be considered, whether these animals may not afford the *volatile* salt attributed to the plants. The doctor does not seem to have considered this; but as they are said to be very numerous in the mass, it will be very necessary to try the effect of a distillation of some of this fermented matter, without these insects; which might be done by covering the whole from the access of flies: For though the Doctor seems to think they are equivocally generated there, it is certain that they owe their origin entirely and only to the eggs of flies. The Doctor seems to think they will of themselves yield no *volatile* salt or spirit; but this is so different from the nature of animal bodies in general, that it may be this opinion was founded on too slight a trial. If the external air be excluded from plants, they will not ferment, and if they are put into a long-necked glass, and left open, they will, in a few weeks, become of a mucilaginous nature; and after standing a year in this manner, they will yield a large quantity of urinous salt or spirit, but not a drop of oil.

Some mosses, and other of the plants usually called imperfect, yield a *volatile* salt on distillation, without previous putrefaction; and some seeds, though in themselves insipid to the taste, have the same quality.

All these spirits and salts have the same properties and effects with the spirits of harts-horn and urine. They change syrup of violets, and many other vegetable tinctures green. They are diaphoretic, diuretic, and deobstruent, and contrary in their nature to acids. They precipitate all metals dissolved in acids, by breaking the force of those acids, and when highly rectified, and mixed with spirit of wine as highly rectified, they make the offa alba of Helmont like all other *volatile* alkali spirits; they unite with acids, and thereby become armoniac or neutral salts. Phil. Trans. N°. 101. p. 7.

Chemical experiments abundantly prove that *volatile* salts are obtainable from all kinds of land animals, the amamphibious and subterraneous tribes, birds, fish, and reptiles, from alkaline vegetables also without putrefaction, and from all other vegetables, after putrefaction, as also from soot, horns, hoofs, and all refuse animal and vegetable matters, such as the pith of horns, urine, the blood of slaughter-houses, &c. and these as pure and perfect as from harts-horn; and this affords a hint for the making *volatile* alkalies and sal armoniac cheap in England. *Shaw's* Lectures, p. 168.

The shootings of *volatile* salts are not limited like those of the fixed and common salts, to any determinate figures, but, by various accidents are thrown into a great variety of pleasing forms. Fanciful people have supposed the shootings of salt of hartshorn, in the tops of the vessels used in subliming it, to resemble the horns of the deers; and that of vipers, to assume the figure of little crawling serpents; but all this is imaginary, and the things from which the salts are obtained have no power to determine their forms, which are governed by more vague principles; such as the peculiar degree of heat, the temperature of the external air, and many other the like uncertain principles.

We have, in the Philosophical Transactions, an account of a whole forest of most elegant trees painted in perspective, in the head of a vessel, by these bodies. The substances employed were sal armoniac and pot-ashes; these were mixed in equal quantities, and put into a tall glass body, which being placed in sand, immediately on the approach of the heat, a large quantity of the salt was sublimed in flowers in the common way; this was a process from which nothing particular could be expected; but after some time the sublimed salt began to assume a regular form, and the head of the cucurbit, which was very large, was filled with the representations of trees so perfect and elegant, that a forest, delineated by the ablest hand, could scarce come up to it.

The figures, though externally numerous, yet were very regular, and all reducible to three kinds; the pine, the fir, and one

one other tree. These, though very exact and beautiful, could have no analogy with the substances out of which the salts were formed, the fir and pine kind yielding so little fixed salt, that they are never employed for this purpose, and the sal armoniac belonging to no vegetable production at all. The same process repeated several times afterward, both with the same salts, and with others of the same nature, never arrived at this perfection; and the whole beauty of this was lost while the spectators were gazing on it, by the sublimation of more of the salt, which filled up all the interstices, and destroyed the figure. Phil. Transf. N°. 105.

The curious in these researches, who would extend the use of these salts to the composing sal armoniac, and many other purposes, for the use of dyers, braziers, apothecaries, chemists, &c. may consult Boerhaave's history of vegetable putrefaction, and his account of sal armoniac, and compare with them the papers of Lemery and Geoffroy, in the memoirs of the Paris academy, on the subject of the preparation of sal armoniac in the Levant, and the imitation of it in other countries.

VOLCANO (*Cycl.*)—Dr. Lister is of opinion, that all the *Volcanoes* in the world are owing to that inflammable mineral called *pyrites*, or *mundic*, a substance consisting of sulphur and iron, and found in great plenty in all those mountains where the *Volcanoes* are found to break out.

The quantities of sulphur continually sublimed in these mountains, in the same manner as the common sulphur is separated by artificial fire from the pyrites in Germany, seems to prove this; and what farther evinces it, is, that the black or purple cinders thrown out of these *Volcanoes* in their most violent eruptions, and wholly differing from the calcined stones or pumice, will be attracted by the magnet, and shew that the whole is very much the same with that caput mortuum of the common pyrites, out of which we have extracted or burnt away the sulphur.

That these *Volcanoes* were all kindled of themselves, at or near the time of the creation, is probable; because there is at present but a certain number of them known, and these have all continued burning at all times, from the earliest history, and none of them have ever been extinguished wholly, or probably ever can be, any other way than by the submersion of the whole into the sea. That they originally kindled of themselves, by means of the pyrites they contain, is very probable, because we find that the pyrites will kindle of itself, and there is no other apparent cause for their kindling; for if we suppose the sun to have done it, the mountain Hecla should have been excused, as standing in a northerly and colder climate; yet this, by all history, seems to have burnt as long as the others.

That they were at first fired my man, is not probable, because it would not be easy to conceive how that should be effected, if attempted; and they are in places the least likely ever to have been the habitations of man, being in the tops of the highest mountains. If we attribute the kindling them to lightnings, or earthquakes, we favour the Doctor's system as much as in his own way; for all these he deduces also from the breath or exhalations of the same mineral, the pyrites, which when fired under ground make earthquakes, when in the air lightnings.

No subject in the whole mineral kingdom is so proper for the keeping up a fire for the many ages these mountains have been burning, as the pyrites. Nothing is so lasting a fuel, and, in general, other fuels become more or less lasting, as they partake more or less of its nature. Scotch coals have more of the bitumen in them, and less of the pyrites than others, and therefore they burn away quickly, and leave only white ashes, without any remains of the pyrites. The common Newcastle coal burns more slowly away, because it contains a far larger portion of the pyrites mixed with its bitumen, as is found by the sulphureous smell it yields in burning; and the Sunderland coal, which contains most of all of this mineral, burns with a more sulphureous smell indeed, but so slowly, that it is said proverbially to make three fires. This burns to a heavy reddish cinder, much resembling the caput mortuum of the pyrites, or the flags cast out of the burning mountains, and contains so much iron, that it is freely attracted by the magnet.

There is, in Ireland, a sort of coal more rich in the pyrites than all these, and seeming indeed to consist in great part of it. This, consequently, keeps up a greatly more durable fire than any of the others, and will remain twenty-four hours red-hot in the fire, without changing its shape. The rise of the breath or effluvia of these pyrites into the air, and their taking fire there, may very naturally cause lightning and thunder there; and it is remarkable, that even the seemingly miraculous accounts of storms of throwing down iron-dust or iron-stones, instead of hail or rain, does not wholly discredit this system; for iron being one part of the constituent matter of the pyrites, it is possible it may have been raised in a vapour with it, and when the sulphureous part was fired and burnt away, it may have again concreted into a solid form, and in that form have falllen to the earth again. Phil. Transf. N°. 157.

The necessity of a subterranean fire is argued from various instances, and from various phænomena.

The places to which this fire is brought up to our view, are generally the tops of mountains; where it may have its free course through their cavities, and burn a length of time, without doing injury to any body.

The subterranean fire could not exist without a communication with the external air; and these *Volcanoes* in the mountains are the spiracles or air holes at which it receives the necessary supplies of it, and by which it communicates with it as much as is necessary for its support. By these the necessary magazines of fire are kept in a due state, and by these they discharge the smoak and foulnesses with which they would otherwise be choaked up and extinguished.

Europe affords five principal openings of this kind. Of these, the chief is Ætna, in the island of Sicily, a *Volcano* famous in all histories. The next to this is Vesuvius, near Naples; then the Strongylus, and some others of less note in the Liparine islands; Hecla in the frozen region of Iceland, and the Chimæra in Greece. The *Volcanoes* of Asia are not less numerous; there are several in the mountains of Persia, and in the island of Ormuz. The pic of Adam, in the island of Ceylon, also burns at certain times: But the principal *Volcanoes* of this part of the world are in the Philippine and Molucca islands. Java and Sumatra also furnish some in the center of their largest mountains. The island of Ternate affords also a *Volcano* on the top of a mountain very difficult of access, but opening with a vast mouth, and very terrible when it burns.

The several violent eruptions of this mountain have given it, within the mouth or Crater, the appearance of an amphitheatre, formed for holding people at the time of some public shew, several circles appearing in it one above another, found with a sort of regularity that is surprising. In Japan there are very numerous instances of the use that mountains serve to on this occasion, many of the higher mountains of that island burning almost continually; and the little islands which lie scattered about in the same sea have also many of them spiracles of the same kind in the tops of the mountains, seen principally in the night, when the absence of the sun's rays gives their faint fire leave to appear.

Whatever may be the number of these *Volcanoes* in Asia, there is no part of the word that yields so many as America. In the kingdom of Chili alone there are fourteen very considerable *Volcanoes*, all placed in a regular order one by the other; and not a less number in Peru; these all burst forth from the summits of those vast mountains the Andes. In New Spain there are three very formidable for the fierceness of their burning.

The most extreme parts of the northern world are not free from these store-houses of fire. Authors tell us of no less than four of them in the most northern parts of Tartary; and we know that Greenland, and all the neighbouring country, has them. The *Volcanoes* of the Terra del Fuego are very well known, and it is indeed the general opinion, that farther north than we have yet penetrated there may be very many undiscovered ones; and some authors have gone so far as to declare, that, were the cold no prevention, we should not be able to come much nearer than we do to the southern pole, for the number and fierceness of the burning mountains.

People who see but a little way into the œconomy of the universe, are apt to blame the author of nature for placing so many of these *Volcanoes* in the habitable parts of the world, and exposing so many of the human species to perish by them; but when the system of nature is more clearly seen into, we find all the reason in the world to admire and adore the goodness of providence in the disposition of these very things.

When it proved necessary to the ends of the creation of the world, that a fire should be kept up within it, where could that be so well kept from doing us injury, as deep in the central parts; and when it was necessary that this fire should have spiracles, or air-vents; where could they be placed more out of our way, than in the tops of the highest mountains, as we constantly and regularly find they are. The smoak, cinders, and other recrements of the fuel that supports the subterranean fire, are by this means discharged far above the heads of the inhabitants, and out of the way of doing them any harm; whereas, had these openings been on plain ground, the whole air the neighbouring nations breathed would have been infected with the stench, and sickness bred with it, beside the danger of firing their houses and towns, and spoiling their cultivated lands with the vast quantities of cinders, ashes, and other matters thrown up, which, as it is, falling on the barren sides of the mountains, do no harm to any thing. The provident placing of these mountains near the sea, either in islands, or on the coasts of continents, is also a great benefit to mankind, as the redundant matter discharged is thrown into the sea, and as there are, in general, higher winds nearer the sea than farther from it, by which the smoak, and with it the malignant vapours of the burnt minerals, are dispersed in the upper region of the air, and never descend in such quantities as to do harm to the neighbouring inhabitants.

This giving vent to the subterranean pyrophylacia, seems one of the great ends of the origin of mountains, and the

other is their ferving, as hydrophylacia or magazines of water. This is feen throughout the world, the rivers that water all the countries inhabited or habitable arifing from chains of mountains placed in their middle, feemingly with this fole intent; the Rhine, the Rhone, and the Danube, all arife from the Alps, the great refervoirs of waters in Europe. The mountains of the moon, placed in the burning fands of Africa, give rife to the Nile and Niger, and other rivers large enough to fupply that vaft and fcorched country; and in the fame manner the river of the Amazons, and the other immenfe beds of water neceffary to fupply the vaft continent of South America, take their origin from the mountains called the Andes. *Kircher's* Mund. Subter. p. 75. feq. See the article MOUNTAIN.

We have an account of mount Vefuvius, and of the eruption from it in 1737, by the prince of Caffano, in the Philofophical Tranfactions, N°. 455. Sect. 1.

The matter thrown out flowed like melted lead, and moved about half a mile in an hour, which was an unufual velocity. The trees, touched by this matter, immediately took fire, and fell. Glafs in houfes was melted into a pafle.

The academy of fciences of Naples made an analyfis of the matter thrown out in this eruption. From which it appears, that this matter contains iron; that it is fpongy at top, and denfe toward the bottom; and, after growing hard, it retained part of its heat above a month. Damps were afterwards feen to arife in divers parts of the mountains. An ammoniacal falt, which gave an extraordinary coldnefs to water in diffolving, was alfo found here. Ibid. See alfo Sect. 2. of the faid Number.

VOLKAMERIA, in botany, the name of a genus of plants, called by Houfton, *duglaffia*, and *paliuro affinis* by Sloane. The characters are thefe: The cup is a one-leaved perianthium, of a turbinated form, very fmall, and lightly indented in four or five places at the end. The flower is one-leaved, and of the gaping kind. The tube is cylindric, and of double the length of the cup. The limb is plain, and divided into five fegments, which are turned toward each fide, but gape principally one way. The ftamina are four very long capillary filaments; the antheræ are fimple. The germen of the piftil is quadrangular. The ftyle is capillary, and of the length of the ftamina, or nearly fo; and the ftigma is bifid. The fruit is a roundifh bilocular capfule, and in this is enclofed a fingle bilocular nut. *Linnæi* Gen. Plant. p. 305. *Houfton*, A. A. *Sloan*, Hift. vol. 2. f. 23.

VOLONES, among the Romans, the antient name of thofe afterwards called *evocati*. See the article EVOCATI.

VOLT (*Cycl.*)—VOLT, in the manege. See the article VAULT, or VOLTE, *Cycl.*

VOLTA, in the Italian mufic, fhews that the part is to be repeated one, two, or more times, according to the numeral adjective joined with it; thus *fi replica una Volta* intimates to play that part once over again.

VOLTA is alfo a fort of dance of Italian origin, in which the man turns the woman feveral times, and then affifts her to make a leap or jump; it is a fpecies of *galliard*. *Broffard*.

VOLTURNALIA, among the Romans, a feftival kept in honour of the god Volturnus, on the fixth of the calends of September, or twenty-fixth of Auguft. *Pitifc.* in voc.

VOLVA, among botanifts, a membranous matter furrounding the bafes of many of the fungi; and in many of them, of very fingular figure and ftructure.

VOLVA is alfo a word ufed by Scribonius Largus, and fome other authors, to exprefs the central part, or, as we call it, the core of the apple, in which the feeds are placed. He prefcribes this in weakneffes of the ftomach, and reachings to vomit.

VOLUBLE *Stalk*. See the article STALK.

VOLVENS *Oculi*, in anatomy, a name given by Spigelius, and fome others, to one of the mufcles of the eye, called by Cowper and Albinus, *obliquus inferior*.

VOLUNTARY (*Cycl.*)—VOLUNTARY, in mufic, a piece played by a mufician extempore, according to his fancy. This is often ufed before he begins to fet himfelf to play any particular compofition, to try the inftrument, and to lead him into the key of the piece he intends to perform.

In the Philofophical Tranfactions, N°. 483. Sect. 2. we have a method of writing down extempore *Voluntaries*, or other pieces of mufic, as faft as any mafter can play them on the organ, or harpfichord; and that in a manner expreffive of all the varieties thofe inftruments are capable of. This is performed by a cylinder, turning equally upon its axis, under the keys of an organ, and by having points under the heads of the keys. Hence, when they are preffed down, they will make a fcratch or mark on the cylinder, which may fhew the duration of the note, and the fituation of this mark on the cylinder will fhew what note was touched. For farther particulars we refer the curious to the tranfaction itfelf.

VOLUNTEERS, in the military art, perfons who of their own accord ferve in the army, and at their own expence.

VOLUTA, the *Volute*, in natural hiftory, the name of a genus of fhells, the characters of which are thefe: They are univalve fhells, and have an oblong mouth, with a clavicle fometimes erect, fometimes depreffed; and they are fometimes coronated at the top. See Tab. of Shells, N°. 10. This genus of fhells is generally confounded by authors with that of the cylindri. There is indeed a general external refemblance between thefe two kinds of fhells at firft fight; but when they are a little examined, they will be found very different. The *Volutæ* are of a conic figure. One of their extremities is of a pyramidal figure, and the other formed into high ribs, which conftitute a depreffed clavicle, or a dentated crown; on the contrary, the cylinder is nearly of an equal fize at both ends. And it is not neceffary to have recourfe to the form of the mouth of this fhell, in order to fix its generical character. Its figure, which is lengthened out into a point in the lower end, fufficiently characterifes this genus; and to this may be added another very remarkable character, which is, that the head is feparated from the body of the fhell by a high rib.

The *Volutæ* are called by many authors, *rhombi*, which is a very ill chofen name, as the word expreffes the figure of a lozenge, a figure very different from that of the fhell. It has been called *Voluta* from the *volute* in architecture, the *volutes* of a capital diminifhing in diameter all the way to the center, which is called the head or eye of the *volute*. See the article VOLUTE, *Cycl.*

The moft remarkable fpecific character in this genus is in the fhape of the clavicle, fome fpecies having it very much elevated, and others very flat or depreffed. The corona imperialis, which is a fhell of this genus, is fingular in the dentated crown, which terminates its head.

The *Volutæ* make the moft rich and beautiful fhells of the whole body of fea productions. Rumphius calls them *eximiæ*; and the admiral and vice-admiral fhells, fo famous among the curious, and held at fo great a price, are both of this genus. The brightnefs of the colours, the perfect white of the enamel, and the elegant fhape of thefe fhells, would make them the firft in efteem among this clafs of bodies, even were they common; but it happens that their fcarcity adds immenfely to their value. There is one of thefe fhells now in Holland, which coft the poffeffor five hundred florins. It is from the bands and fafciæ of thefe fhells, which refemble the colours of fhips, that they have obtained the names of admiral and vice-admiral.

Some of the Hollanders give to another fhell of this kind the name of extra-admiral; this refembles the admiral, but has its colours arranged without divifions of the white enamel. It is a very fcarce fhell, but is lefs beautiful than either of the two others.

The family of the *Volutæ* being numerous, the fpecies may be aptly ranged under three general heads. 1. Thofe with an exerted clavicle. 2. Thofe with a depreffed clavicle. And 3. Thofe with a coronated clavicle.

Of the firft kind we have the following fpecies: 1. The grand *admiral*, or *archithalaffus primus*. 2. The *archithalaffus fecundus*, or the *vice-admiral*. 3. The *archithalaffus araufcanus*, or the *orange-admiral*. 4. The navel or baftard *admiral*. 5. The fpectre-fhell, or *concha fpectrorum*. 6. The brown lineated *Volute*. 7. The flame-coloured *Volute*. 8. The Guinea-fhell, or fpeculation *Volute*. 9. The reddifh ftriated and fafciated *Volute*. 10. The punctulated *Volute*. 11. The Hebrew *Volute*. 12. The brown *Volute*, with two elegant white zones. 13. The Ifabella *Volute*. 14. The *vexillum*. 15. The *Volute*, variegated with two reticulated zones. 16. The bat *Volute*. 17. The white *Volute*, with yellow fpots and lines.

Of the fecond kind, or thofe with depreffed clavicles, we have the following fpecies: 1. The black leopard *Volute*. 2. The yellow leopard *Volute*. 3. The reddifh leopard *Volute*. 4. The chequered *Volute*. 5. The blue fpotted *Volute*. 6. The fafciated *Volute*, with yellow and white fpots. 7. The butter-tub *Volute*. 8. The agate-coloured ftriped *Volute*. 9. The yellow *Volute*, with a white circle. 10. The onyx *volute*. This, when its outer coat is taken off, is of a true onyx colour, and it is in this ftate that it is ufually met with in the cabinets of collectors. 11. The butterfly-wing *Volute*. 12. The green fpotted *Volute*, with two variegated fafciæ.

Of the third kind of *Volutæ*, the head of which is coronated, we have the following fpecies: 1. The *crown imperial*. 2. The lefs fafciated *crown imperial*. 3. The *crown imperial*, variegated with brown. 4. The black marbled *crown imperial*. And 5. The *crown imperial*, called in French the *moire*; this feems of the texture of the web of a filkworm, only more clofely woven together. Hift. Nat. Eclair. p. 279.

VOLVULA, in natural hiftory, the name of an extraneous foffile body, nearly allied to the entrochus, being compofed of the fame fubftance, and being like that of a cylindric column, made up of feveral joints; the commiffures of the joints are, however, much lefs vifible in the *Volvulæ* than in the entrochi, and they are not ftriated, as in the entrochus, from the center to the circumference.

The *Volvulæ* are of various figures, fome refemble in fhape a little bottle, and are called *Volvulæ utriculatæ*, and of thefe fome have, and others have not, a ftar marked on their bottom; others of them fwell out in the middle, and taper a little toward each end; and thefe, from their refemblance in fhape to

to a little barrel, are called *dolioli*, or *Volutæ doliatæ*. There is great reason, from the analogy these bear to the entrochi, and other fossils which owe their form to animal remains, to suppose these of the same origin; but we yet know not to what animal it is that they have belonged. *Hill's* Hist. Foss. p. 653.

VOLVULUS, in botany, a name given by Daleschamp, and some others, to the upright narrow leaved or toad-flax-leaved bind-weed. See the article CONVOLVULUS.

VOMER (*Cycl.*)—The situation of this bone is perpendicular between the two nasal fossæ backward. It is in figure nearly of an oblique square. Anatomists divide it into the right and left side, both of which are unequally flat; and four edges, the superior, inferior, anterior, and posterior; the upper edge is an horizontal groove, which receives the sharp process or rostrum of the os sphenoides. The anterior edge is oblique, and very unequal; its posterior part is small and thin, and supports the perpendicular lamina of the os ethmoides; the anterior is larger, with a pretty deep groove, continued from the canal in the upper edge, which sustains the cartilaginous septum of the nares. The lower edge is likewise unequal; and near its anterior extremity is an angle, which divides it into two parts; one anterior, very short, which is set in the crista narium; the other posterior, and much longer, set in the common groove of the ossa maxillaria and palate. The angle by which this edge is divided, lies in the notch formed by the crista narium, and the groove of the maxillary bones. The posterior edge is oblique and sharp, becoming insensibly more obtuse as it approaches to the larger groove in the edge. This bone has but very little diploe; it is connected with the os sphenoides, os ethmoides, ossa maxillaria, and ossa palati; its use is to form the posterior part of the septum narium. *Winslow's* Anatomy, p. 38.

VOMICA (*Cycl.*)—VOMICA, in natural history, a word used by the antients to express one of the blemishes to which crystals and the precious stones are subject. This is a dusky foulness lying deep in the stone, and giving a dusky colour and tinge to the whole. Both the lustre and transparence of the stone is much hurt by this accident. When the *Vomica* was of a bluish or blackish colour, the Romans expressed it by the word *plumbago*. See the article PLUMBAGO.

VOMICA *Pulmonum*, in medicine, the name of a disease which is a sanious collection of matter, or an apostem formed in the lungs, and included in its own proper membrane; this sometimes seizes one lobe, sometimes the other; and sometimes lies deep in the substance, sometimes near the surface. It finally breaks, and then discovers itself by a discharge of purulent matter from the lungs.

The signs of this disease are at first very distinct; it generally begins from a hard node, which, by slow degrees, ripens into a collection of matter. A hectic fever is a constant attendant on it, and there is always a dry cough attending it; but this is not very violent. Toward the ripening of the matter, there is a difficulty of breathing, and often the patient complains of a dull heavy pain, sometimes of a very acute one, in some particular part of the breast. The face is irregularly red, and a languor grows upon the whole body. The appetite is irregular, and finally a fever comes on; and during this the swelling breaks, and the matter is thrown up in such large quantities, as to endanger suffocation.

The most fatal diseases are usually the most rare, and this is of that number, seldom being met with, and when it is, too often fatal. The causes of it, are stagnation of the blood in plethoric habits, in the vesicles of the lungs; and these are usually owing to the suppression of natural habitual evacuations, or the omission of artificial ones, as habitual bleedings and the like; to these are to be added, external injuries from falls, blows, or wounds of the breast; violent running till out of breath, and a sudden cooling of the breast while the body is hot.

The usual causes of the breaking of a *Vomica*, when formed, are violent succussions of the body, loud speaking or calling, violent coughing or sneezing, and the falling of any substance in eating into the windpipe.

Prognostics in it. The more slowly this disease advances to its height, the more difficultly it is discovered; and the deeper it lies in the substance of the lungs, the greater is the danger of it; though, when most superficial, it is of no small danger; for, breaking externally on the lungs, it discharges its matter into the cavity of the thorax, and thus makes an empyema, a distemper little less fatal than the other, unless the matter be immediately let out by the paracentesis. When the matter has lain deep, there is great danger of the person's being suffocated either at the first discharge of it, or at the succeeding ones, if they are large, and he be already wore down by a hectic, as is usually the case; and even if he escapes this, the apostem degenerates into an ulcer, and so brings on a phthisis.

In general, the smaller the quantity of matter thrown up, the less is the danger.

Method of Cure. The same general medicines are to be used as in a phthisis. The apostem is to be cleansed and absterged, which is done by pectorals mixed with discutients; such are liquorice, hyssop, and the seeds of carduus mariæ. Then the solution of continuity is, if possible, to be repaired. This is to be attempted by balsamics, such as comfrey, plantain, ground ivy, and the like. The febrile heat is to be allayed by mixtures of nitre and diaphoretic antimony; and the violence of the cough abated by the use of gentle opiates, such as storax pill, and the like, in small doses.

The bowels are to be kept open by clysters and gentle purges; revulsion is to be made by bleeding in the foot, and after this, the pectorals, &c. are to be relied on. And during the whole course a light diet, and tranquillity of body and mind are to be prescribed. *Junker's* Consp. Med. p. 173. seq.

VOMIT. The effects of *Vomits*, on the motion of the blood, appear by the following experiments: By observing the pulse of several men, after taking a *Vomit*, it has been found, that so soon as a man begins to grow sick, his pulse becomes low, quick, and irregular, and, in the action of *Vomiting*, is often so low as not to be felt; that in the intervals, between the *Vomits*, the pulse is still low and quick, but not near so low and quick as in the action of *vomiting*; and that, after the operation is over, the pulse rises gradually, and in the space of half an hour, or an hour, becomes fuller than it was before the *Vomit* was taken. Hence we see the effects of *Vomits* on the motion of the blood, they lessen that motion during the whole time of their operation, and almost quite stop it in the very act of *vomiting*; and after the whole operation is over, they increase the motion of the blood, so as to make it greater than it was before.

From these effects of *Vomits* on the motion of the blood, we discover their great usefulness in the cure of many diseases. For instance, *Vomits* stop hæmorrhages from small vessels. For when a blood-vessel is opened, the blood flows faster thro' that vessel, and slower through all the rest of the vessels, than it did before. And therefore, all that is necessary to stop a hæmorrhage from a small vessel, is to stop the motion of the blood in that vessel, and increase its motion in all the other vessels; and both these are done by *Vomits*, as appears by the foregoing experiments.

The increasing the motion of the blood in all the other vessels, will lessen the motion in the vessel supplying the hæmorrhage, and thereby effectually prevent a return of the discharge. For the same reason, *Vomits* lessen immoderate discharges of the glands, and ulcers; for they lessen the motion of the blood and humours in the parts affected, by increasing their motion in all the other parts. By increasing the blood's motion, repeated *Vomits*, with a proper diet, has been found to be of great service in dispersing scrophulous tumours; which may be allowed, when it is considered that these tumours are most incident to children and young bodies, the motion of whose blood is slow; and that they often disappear of themselves, when bodies are grown up, and their blood has acquired a stronger motion.

When obstructions arise from too lanquid a motion of the blood, *Vomits* are generally of use in removing them. And when the motion of the blood is too great, and the obstructions are formed by cold, *Vomits*, after large bleeding, will be of great service in removing them. In short, *Vomits*, repeated according to the nature and obstinacy of the disorder, are generally of service in all irregularities, and disproportions of the motions of the blood, and other fluids, in different parts of the body. The safety, as well as usefulness of frequently repeated *Vomits*, is evidently seen in persons at sea, and in women with child. Persons at sea, who are sick, and *vomit* much, are commonly the better for it; and frequent *vomiting* in women with child, is of service, and prevents abortion. As all muscles grow stronger by exercise, so the muscular coat of the stomach grows stronger by *vomiting*. Dr. *Br. Robinson*, of the Food and Discharge of Human Bodies. See the article VOMITING, *Cycl.* and *Suppl.*

Some have pretended to give rules for ascertaining the doses of *Vomits*. See the article PURGATIVE.

Mustard VOMIT. See the article MUSTARD.

VOMITING (*Cycl.*)—The causes of *Vomiting* are very different, and the treatment of it as a disease, must therefore be also various, according to those differences.

Critical *Vomitings*, by which humours of various kinds are discharged by the operation of nature alone, are salutary, and scarce require any care as to their cure; but are, in many cases, to be promoted: whereas symptomatical *Vomitings*, which are less sufficient, or less accommodated to the removing the cause, are more carefully to be treated, in order to their cure.

The two principal curative indications to be observed are, first, to quiet and compose the convulsive and unruly motion of the stomach; and secondly, to oppose and subdue the material causes of the disorder.

The first intention is answered by corroborating and antispasmodic medicines, such as saffron and castor, with the testaceous powders, as coral, crabs-claws, and oister-shells; powders composed of cinnamon, the leaves of mint, nutmeg, orange-peel, calamus aromaticus, and other such simples, are also of great service. And if anodynes are found necessary, the storax pill, or Sydenham's laudanum, are to be given.

While these medicines are taken internally, there may also be applied outwardly to the region of the stomach, such things as

as have power to reprefs its diforderly motions; of this kind are the oil of mint, nutmeg, and the like, with balfam of Peru: thefe oils may be reduced to a proper confiftence, with this balfam, for the fpreading on leather, and lying on for fome time. Hungary-water, and other the like fpirits, are of great ufe alfo, rubbed on with the hand; and to thefe may be added yeaft, and the ftrongeft wine-vinegar applied hot to the part. Finally, an excellent application is balfam of Peru alone, reduced to the confiftence of a cataplafm, with crumb of bread.

The methods to be ufed to remove the material caufes of the *Vomiting*, are next to be confidered: If it be of the pituitous kind, and owing to crudities in the primæ viæ, and a vifcid mucus fticking to them, it is beft cured by an emetic: if the *vomiting* of itfelf be found not fufficient to carry off the fordes which occafioned it, and the patient continues, after the fits of *vomiting*, afflicted with a naufea and heart-burn; in this cafe, a large quantity of warm water, with a little butter, may ferve the purpofe; or if this be found infufficient, a dofe of ipecacuanha is to be given. *Hoffm.* Oper. T. 3.

When infants are afflicted with *vomiting*, from milk coagulated upon their tender ftomachs, which is a very frequent cafe, the beft medicine is a mixture of oxymel of fquills, and fyrup of rhubarb. See the article INFANT.

In cafes of bilious *Vomitings*, which arife from a weakened digeftion, and have their fomes in the duodenum, the cure is to be begun with the abforbent and teftaceous powders; after thefe, gentle purges of rhubarb and manna are to be given; and finally, the cure is to be perfected by reftoring the ftrength of the ftomach and inteftines.

In *Vomitings* which arife from an acrid matter adhering to the nerves of the ftomach, from the retropulfion of the gout, an erifipelas, or other fuch diforder, the mild fedatives are to be given, and with them fuch medicines as promote the expulfion of the matter; and all means are to be ufed to remove it to the furface of the fkin, or to the extremities again. All fweating medicines are good in this intention, as they carry the matter to the furface. Camphor, taken internally in moderate dofes, is alfo of great fervice; and warm baths for the feet often prove highly ufeful. In *Vomitings* excited by poifonous fubftances, nothing gives fuch immediate relief as the taking large quantities of warm milk, and pinguious liquors; for by means of thefe the fpicula of the poifon are blunted, and afterwards *vomited* up with the liquors. And hence in contagious and peftilential cafes, where there is no inflammation of the ftomach, many phyficians have very fuccefsfully given *vomits* of ipecacuanha, and after thefe acid liquors with diaphoretics.

Acrid, acid, and bilious fordes falling upon the inteftines, often occafion a *vomiting*, attended with colic pains; in this cafe, fmall dofes of oil of fweet almonds and manna, with large draughts of barley-water between the dofes, are found of great fervice; and fmall dofes of laudanum, at proper times, ferve to compleat the cure. In perfons of hot habits, fpirit of vitriol, and mild laxatives, are found of moft certain relief.

The too frequent method of attempting to ftop a *Vomiting* by aftringents and anodynes, before the peccant matter is removed, is highly blameable; for when the fpafmodic motions are allayed, which nature ufed to free herfelf from this matter, and that yet remains behind, there muft follow worfe fymptoms. Thefe remedies which affect the motion only, and not the matter, are only to be ufed when the motion fubfifts, after the matter is difcharged, or when the motion is very violent, and the matter to be thrown off but very fmall in quantity.

Hence in *Vomitings* exited by the chin-cough in children, fedatives and anodynes are very proper, fuch as the fyrup of red poppies, or diacodium, and a little oil of fweet almonds.

The *Vomitings* of pregnant women, arifing from a regurgitation of the blood to the ftomach, which is alfo obferved in women afflicted with a retention of the menfes, and in men who have a ftoppage of habitual hæmorrhoidal difcharges, are beft removed by temperating medicines, mild laxatives, emollient clyfters; and beft of all, by bleeding, or recalling the natural fecretions of blood, in the two latter cafes. On fuch occafions it is highly improper to give emetics, for they fometimes bring on a *Vomiting* of blood, and fometimes an inflammation of the ftomach.

In cafes of efforts to *vomit*, or actual *Vomitings*, in the morning, which frequently happen to thofe who ufe too much ftrong liquors over night, the teftaceous powders are to be given, and all other things which will abforb acidities; and after thefe the grateful ftomachics, fuch as candied orange-peel, and the like.

Chronical *Vomitings* fometimes affect perfons who have been in a long continued ftate of grief; in this cafe the beft relief is found in analeptics, and the ufe of cinnamon-water, impregnated with quinces, and of the generous wines.

In *Vomitings*, which are a fymptom of fevers coming on, the ufe of a gentle emetic, fuch as the ipecacuanha is very proper. In the fmall pox, the *Vomiting* ufually ceafes fpontaneoufly after the eruption of the puftules, and in thefe and many other cafes, great relief is to be obtained in *Vomitings*, by a mixture of falt of wormwood and juice of lemons.

In *Vomitings* arifing from fits of the ftone, the fpiritus nitri dulcis often proves of great fervice; and oily glyfters, and oil of fweet-almonds, taken internally, are alfo of great fervice. The *Vomiting* of perfons in hernias, or the iliaca-paffio, rarely remits till the caufe ceafes. Reft, and lying in bed, contribute greatly to the ftopping immoderate *Vomitings*, for all motion of the body excites in thefe cafes a frefh tendency to *vomiting*. In the beginnings of eryfipelas's, and the like diforders, *Vomitings* often happen, and thefe are by no means to be checked; but the appearance of the difeafe externally is to be forwarded by diaphoretics; for as foon as the eruptions appear, the *Vomiting* ftops of itfelf.

The obftinate *Vomitings* of hyfterical patients are not to be ftopped by opiates or aftringents; for the confequence of this is ufually violent convulfions in the limbs, and anxieties and pain in the præcordia; all which fymptoms difappear again, as foon as the *Vomiting* returns.

The immoderate and long-continued *Vomitings* of pregnant women, which principally happen in the firft months of the time, efpecially in thofe who indulge themfelves too much in venery, and are plethoric, are by no means to be cured by aftringents, opiates, or fpirituous medicines; but are to be removed by repeated bleeding in the ankle, reft of the body, and tranquillity of the mind. And when *Vomiting* of this kind is fo violent as to threaten abortion, it is often ftopped more effectually by the drinking cold water, than by any medicine whatfoever. When an analeptic is neceffary, one fpoonful of cinnamon-water, taken after meals, is fufficient. *Hoffman*, Op. T. 3.

VOMITINGS *in Infants*. See the article INFANT.

VOMITING *of Blood*, *Vomitus Cruentus*, a very dangerous kind of hæmorrhage, confifting in a bringing up by *Vomit* of pure and unmixed blood from the ftomach, and being a method, ufed by nature to throw off a portion of the blood, which molefts the whole in the vena porta, and by that means to facilitate the circulation of the reft of the mafs.

This diftemper fometimes arifes from internal caufes, and is regularly periodical, obferving the ftated times of the eruptions of the menfes, or other natural difcharges; fometimes it arifes from accidents, fuch as the giving of violent purging or emetic medicines, or corrofive ones.

Preceding Signs of it. Among thefe are to be reckoned a fenfation of ftraitnefs and anxiety in the præcordia, with tenfion, and involuntary fighs; with a naufea or ficknefs of the ftomach, and a ftraining to vomit; which is more violent than in vomiting on any other occafion; after this the blood is thrown up pure, and the *Vomiting* then ceafes, till, after a plain fenfation of more blood being collected in the ftomach, the efforts to difcharge it in the fame manner are again renewed. The quicker the blood is thrown up, after its being difcharged into the ftomach, the more fluid and more florid it appears; the longer it is detained there, the blacker and thicker it appears.

Perfons moft fubject to it. A *vomiting* of blood is but an uncommon diforder. It more frequently attacks women than men; among the female fex it is principally feen in thofe whom the menfes have left too early in life, or who have had violent fuppreffions of them for a long time. In men, this diftemper feldom feizes any but thofe who have been ufed to periodical difcharges from the hæmorrhoidal veffels, and who have had them fuddenly ftopped; and they are then ufually firft attacked with violent pains in the left hypochondrium. People of fcorbutic habits, and fuch as have had quartan agues of long ftanding, have been fometimes thus affected. And, befide thefe natural caufes, people of all ages and fexes may vomit blood, from external injuries.

Prognoftics from it. A *Vomiting* of blood is ever a dangerous diforder; for tho' the quantity of blood thrown up is feldom fo great as to occafion immediate death, yet it generally degenerates into a tabes in men, and into a cachectic habit in women. It is lefs dangerous to young women, than to any other perfons; and when it is periodical, efpecially when it obferves the times of the menftrual difcharges, is much lefs dangerous than under any other circumftances.

Method of Cure. During the paroxyfm, the proper medicines are powders of nitre, cinnabar, and the abforbent fubftances, fuch as crab's-eyes, or the like, and afterwards bleeding, cupping, and gentle purges, and diaphoretics are to be given for fome time. *Junker*'s Confp. Med. 35.

VORTEX (*Cycl.*)—We have, in the Philofophical Tranfactions, a phyfico-mathematical demonftration [a] of the impoffibility and infufficiency of *Vortices* to account for the cœleftial phænomena.—[[a] By Monf. de *Sigorne*. See N°. 457. Sect. 6. p. 409. feq.]

This author endeavours to fhew, that the mechanical generation of a *Vortex* is impoffible; that it has only an axifugal, and not a centrifugal and centripetal force; that it is not fufficient for explaining gravity and its properties; that it deftroys Kepler's aftronomical laws; and therefore concludes with Sir

Isaac Newton, that the hypothesis of *Vortices* is fitter to disturb than explain the cœlestial motions. We must refer to the dissertation itself for the proof of these assertions.

VOTE (*Cycl.*)—In elections of members of the house of commons, such *Votes* shall be deemed legal, which have been so declared by the last determination in the house of commons; which last determination concerning any county, shire, city, borough, cinque port, or place, shall be final to all intents and purposes. Stat. 2. Geo. 2. c. 24.

UPLAND (*Cycl.*)—The *Uplands* lie either on the tops of hills, or on their sides, or on the slopes of rising grounds. They sometimes have a sandy soil, sometimes a rocky, gravelly, or loamy one, and sometimes they consist of tough clay, or a black mould. They are used by the farmers either for grazing or corn, as they happen to be more moist or more dry; and this difference depends upon their situation and nature.

Those lands which lie flat upon the tops of hills, are usually the driest, and those which form the slopes or sides, are usually the moistest, because of the wet that is continually oozing through them. The chalky, and especially the clayey sods in these places, are most of all subject to be wet, especially in winter, because they retain the moisture a long time; though they have also the inconveniencies of the sandy and rocky lands in the same situations, chapping in summer. The black mould, and the hazely loams in these places, are the best for corn, as well as for pasture, especially if the latter escapes the common misfortune of being full of worms. These lands neither are washy in winter, nor parched up in summer.

The *Upland* meadows have some disadvantages, as they often need mending or feeding, which those that lie lower do not; but then they make amends for this in their hay, which is always much finer and sweeter than that of the low-lands.

UPLOPER, a name given to one particular species of pigeon, called by Moore, *columba gutturosa saliens*.

It was first brought to England from Holland, and much resembles that kind of pigeon called the English Powter, but that it is smaller. Its crop is very round, and in this it buries its bill. Its legs are very small and slender, and its toes are short, and close together, on which it treads so nicely, that, when moving, any small thing might be put under the ball of its foot. The pigeons of this species are generally all blue, all black, or all white; seldom or never pyed. They are very scarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word *Oplopen*, which signifies to leap up, and it was thus named from its manner of approaching the hen, which is always by leaping upon her. *Moore's* Columbarium, p. 37.

UPRIGHT (*Cycl.*)—UPRIGHT *South Dial.* See the article PRIME *Vertical*, *Cycl.*

UPULUS, in botany, the old Latin name for the *lupulus*, or hop. This word *lupulus* is not old Latin, but a more modern name, formed on the word *Upulus*.

The original word *Upulus* also was formerly written *opulus*, being a climbing plant. The word was also applied to other climbing plants, such as the white and black bryony. Some of the antients called the hop *upulus salictarius*, because of its twining about willow-trees. Pliny mentions it under this name. The words indeed stand *lupus salictarius*; but this is a very plain error, since the *salictarius* is joined to the word *Upulus* by Cato, Varro, and most of the other writers of antiquity; but by no body to the word *lupus*. Cato in one place calls it *ulva*; but this is evidently an error of the copy. The word *ulva* is the name of a sea-plant growing without stalks, composed only of tender leaves; and it is here called a tall plant, climbing upon the willows. There is no doubt from this, and from the same author's ordering it to be strewed under cattle, by way of litter, that it was the *Upulus* or *lupulus*. See the article LUPULUS.

UPUPA, the *Hoopoe*, in the Linnæan system of zoology, makes a distinct genus of birds, the characteristic of which is, the having a double crown of feathers on the head. *Linnæi* Syftem. Nat. p. 45.

These birds are common in Germany, and sometimes seen in England, though but rarely. Its general weight is about three ounces. The beak is black, slender, sharp, and a little hooked; its head is adorned with an extremely beautiful and elegant crest, rising two fingers high, and composed of two series of feathers, reaching from the insertion of the beak to the back part of the head; and these can be raised or depressed by the bird at pleasure. The tips of these feathers are ornamented with black and white, the rest is of a chesnut colour. Its neck is of a pale reddish brown; its breast white, variegated with longitudinal streaks, which disappear in the middle as the bird grows older; the tail is four fingers breadth long; it is composed of ten feathers, and is black; but has a large white spot in it, of a lunated figure, the points standing towards the extremity of the tail. Its wings, when folded, do not reach to the end of the tail; and are streaked across with white; it feeds on beetles, worms, ants, &c. and is said also to eat berries, and other vegetables. *Ray's* Ornith. p. 100.

Æschylus, Aristotle, and many of the other old Greek writers tell us, that the cuckow, when it has sung all the summer, acquires a plume of feathers on its head, and loses its voice for the winter season, and is in this state called the *Upupa* or *Hoopoe*; but there is no truth in this story, though the general opinion of those times.

In the same manner they supposed the *ficedula* and *melancoryphos*, or black cap, to change into one another; because the one appeared at that time of the year when the other went away. We have in this bird also another proof of the ignorance of those times in natural knowledge: they tell us, that the callais or turquoise, which we call the *Turkey-stone*, was found in the melancoryphus only, because the eggs of that bird are of the same beautiful pale blue colour with that gem.

URACHUS (*Cycl.*—The use of the *Urachus* is not yet discovered, according to Dr. Trew. Phil. Trans. N°. 457. Sect. 7. See the articles ALLANTOIS and FOETUS.

URANOSCOPUS, in zoology, the name of a fish of the cuculus kind, called in English the *star-gazer*; and by some authors, *callyonymus*.

It is usually caught of about seven or eight inches in length, but sometimes it grows to a foot; its head is very large, bony, and rough, and of a sort of square figure; its body is long and rounded; its upper part is all of an ash-colour; its belly white; its scales are very small and thin, insomuch that many have supposed it had none. These are dispofed in oblique ranges across the body of the fish, running toward the tail. The side-lines are arched, and rise to the back fin, which is a great singularity. Its face is flat, and seems turned upwards, and its eyes are small and prominent, and are so placed in the upper part of its head, as naturally to look up to the heavens, whence it has its name. Many of the flat fish have their eyes placed as those of this fish; but the pupils in all these look sideways; in this only they are turned strait upward. Its mouth is very large, and opens perpendicularly downward, being placed in the same direction with the eyes in the upper part of the head. It has a beard under its chin, like that of a man, and its jaws are furnished with very sharp teeth, as are also the inner parts of its mouth. Its whole head is covered with rough tubercles, and it has two fins on the back, and two on its breast. It is frequently caught in the Mediterranean, and is by some said to be a well-tasted fish. *Gesner*, de Aquat. p. 159.

The reason of the situation of the eyes of the *Uranoscopus*, is the providence of nature for a fish which, always keeping at the bottom, has no where to look for prey but in the water above it. But if other fish had been well examined, this peculiar name would never have been given to this. The eyes of the *rana piscatrix* are placed in the same manner, and those of a great number of other fish, whose custom it is to keep at the bottom, are more or less also thus situated.

According to the new system of Artedi, this is a species of the *trachinus*, and is distinguished from the others of that genus, by the name of the *trachinus* with many beards on the lower jaw. The fish described by Willughby and others under the names of the *sea-dragon* and *sea-spider*, the *draco-marinus* and *araneus-marinus*, are of this genus. They are properly indeed only the same species in different states, and are distinguished from the *star-gazer* by the name of the *trachinus* with the lower jaw longer than the upper, and with no beards hanging from it. *Artedi* Gen. Pisc. 73. See Tab. of Fishes, N°. 48. and the article TRACHINUS.

URCEOLUS, in ecclesiastical writers. See the article AQUÆ *Manilis*.

URCEUS, in antiquity, the name of a measure of liquids, which in different places was of different capacity; its most usual standard seems to have been between twelve and sixteen ounces.

URCHIN, a common name given to the hedge-hog. See the article ERINACEUS.

Sea-URCHIN, in ichthyology. The *echinus marinus* of authors is, in some parts of England, called the *sea-egg*, and in others the *sea-urchin*, or *hedge-hog*. It is a genus of fish, of which there are a great number of species.

The manner of these creatures moving at the bottom of the sea, has been disputed among naturalists; the general opinion of the world has been, that they did it by means of their spines or prickles, which served them by way of legs; but some of late, particularly Mr. Gandolphe, pretend that the spines of the *Urchins* are of no use to them on this occasion, but that they move by means of certain legs, like the legs of the star-fish, which they occasionally put out when they walk, and at other times retract them into their body. The world was readily falling into this system, particularly as Mr. Gandolphe affirmed, that he had been often an eye-witness to it; but the indefatigable Mr. Reaumur tried the experiment himself, and often made himself an eye-witness of the contrary fact, having frequently seen them walk at the bottom of a shallow bason of sea-water, with no other assistance than that of their spines, and even having made them perform the same motion, by the same means, upon his hand.

This curious enquirer into nature did not, however, stop here; but took occasion from hence to enquire accurately into every circumstance of their progression, which is performed by so uncommon means.

It is certain that the *sea-Urchin* does throw out at the lower

aperture of its shell, when it pleases, certain bodies which resemble not a little the legs of star-fish; but these serve not at all to its motion; but, on the contrary, their real use is to keep the creature still, and fixed in the same position; and, to describe them more exactly, they very aptly resemble the horns of snails; whence Mr. Reaumur has chosen rather to call them horns than legs. The use the *Urchin* makes of these horns, while it is in motion, is to feel about, and try the ground on which it marches; and they serve the creature as a staff does a blind man in his walking, to touch and try every thing that lies in the way; and to make them serve to this purpose, it is continually extending or retracting them during the time it is moving. These horns are not only placed about the orifice of the shell, but they are every where dispersed among the spines, all over the surface of the shell.

To understand properly the position of these horns, it will be necessary to consider the figure of the *sea-Urchin* shell, as we usually see it, that is, stripped both of its spines and its horns. In this state it appears a very beautiful piece of workmanship. It is a hard body, the figure of which approaches to that of a segment of a sphere, or a mould of a button hollowed within; it has an aperture at the very summit of the shell, and another at the base, just opposite to it; this is the case in the common kind; for there are great varieties in the place of these holes, in the different species: at this lower aperture is placed the mouth of the animal; the upper is supposed to serve it to discharge the excrements by. The whole external surface is covered with protuberances of different sizes, but all disposed in a beautiful and regular order; they divide the whole surface, as it were, into ten spheric isosceles triangles, all which have their summit at the upper aperture, and their base at the lower. Of these there are five large and five small; but all the large ones, and all the small ones, are regularly of the same size one with another. There is a small band, which is less rough than the other parts, which separates every larger from every smaller triangle; these bands are also in themselves so many triangles; but the calling them by this name, will better serve to distinguish them from the others. As the triangles, both large and small, are all covered with eminences or protuberances, these bands are, on the contrary, all pierced with small holes; these run quite through the shell, and their apertures are more sensible on the inside than on the out. These holes are beautifully distinguished, on holding the shell against the light, and are arranged in a very beautiful order, and in regular series on every band. There are two sorts of ranges of these upon every band, one sort containing two holes all the way, and the other four; these are placed in a regular alternate order; first, a range of two, then a range of four, then another of two again, and so on to the extreme edge of the band.

The space contained in every triangle is also in the same manner divided into several parts by a number of lines, which begin at the upper aperture of the shell, and terminate at the lower; but as these lines in the bands are marked by little perforations, they are, in the triangles, made of those eminences which render the surface of the shell rough and uneven; those eminences which are in the middle of every line, are larger than those which come towards one or the other end; and the several different lines are made up of these eminences of different sizes one from another, so that, on the whole, there is every where a great variety of them. Every one of these eminences resembles a sort of teat or nipple, with a portion of the breast; or, to give a more determinate idea of them, each is a portion of a sphere, the summit of the convexity of which is crowned with another portion of a much smaller sphere. These are the parts on which the base of every spine of the *Urchin* is fixed; and as this base is hollow, it naturally envelopes the small portion of a sphere at the summit of each eminence, and is able to move and turn any way upon it, in the manner of the ball and socket articulations. The smaller eminences sustain the smaller spines, and the larger the great ones; the number of these eminences, or, in other words, the number of the spines on one fish, is surprizing; many of them are so small, that it is not easy to count them regularly; but Mr. Reaumur found, in general, that there were considerably more than two thousand on every fish; nor is the number of the perforations before-mentioned less to be wondered at; they take up but a very small space on the shell, in proportion to the spines, yet Mr. Reaumur observes, that their general number in every shell cannot be less than thirteen hundred. From knowing the number of these perforations, we are able to determine that of the horns; for every horn has its origin from one of these. The horns are never seen all together, they are only visible when the creature is in the water, and even then it only exerts some of them at a time, so that it is not to be expected that they should all be seen together. When it is in motion, it only shews those which are placed on that side of the shell which is to move forwards in the journey; and when it is at rest, we only can see those which it thrusts out, and fastens to stones or other bodies, to fix itself by. These serve by way of anchors to the creature, it glews them fast down to the stones, *&c.* and if the creature be forcibly removed, they are generally, in part, if not entirely, broken and destroyed by it. When the creature is taken out of the water, they are no more to be discerned, they are bent and folded together, and are in a flaccid state, so that nothing but their ends can be at all perceived, and these no body can tell what to make of, who has not before seen them in their exerted state in the water.

The spines are all capable of assisting the creature in its motions, but those it principally employs are such as are placed near its mouth, as these can turn upon their balls every way with equal facility, the creature finds it equally easy to move on any side; and when it has determined which way it will move, those spines which stand directly toward that point, and those which are directly opposite, are of equal service to it; it draws itself forward by means of the first, and pushes itself on with the others; to do this, it first thrusts out the foremost ones as far as possible, and pressing them against the bottom, it draws on its body by them; and this is succeeded by its drawing up the hinder ones close to its shell, and then fixing them against the bottom, it pushes itself forward by them. This is the manner of this little creature's marching in the common way with its mouth downward; but it has this strange singularity, that it is not confined to this posture alone in marching, but can, with equal ease, walk with its mouth upwards, or run along sideways in the manner of a wheel; or in any direction between these. The legs and the horns cover all parts of it, and are in every part of it equally able to move it every way. What a prodigious number of muscles must this little creature have to be able to move separately thirteen hundred horns, and more than two thousand spines, which serve for legs. Mem. Acad. Par. 1712.

UREDO, a word used by some of the chemical writers to express the virtues of metals communicated to them from the sun. Pliny uses the same word to express the smut affecting fruits; and some medical writers have expressed by it a very violent and excruciating pain in the head. See the articles SMUT and BLASTS.

URENA, in botany, a name given by Dillenius to a genus of plants, the characters of which, according to Linnæus, are these: The cup is a double perianthium; the external one is composed only of one leaf, divided slightly into five broad segments; the inner one is composed of five narrow and angular leaves. The flower is composed of five oblong petals, which are broadest at the apex, and end in an obtuse point, and at their bases are narrow and grow together. The stamina are numerous filaments, which at their bases grow together into a cylinder, but stand free at the tops. The apices are roundish. The germen of the pistil is roundish; but it is formed into five angular prominences. The style is simple, and of the length of the stamina, and is crowned with ten stigmata, which are headed, reflex, and hairy. The fruit is a roundish pentangular echinated capsule, being composed of five valves, and containing five cells. The seeds are single and roundish, and at their ends somewhat compressed. *Linnæi* Gen. Plant. p. 329. *Dillen.* Hort. Eltham. p. 319.

URETHRA (*Cycl.*)—The hard knots which are sometimes formed in the corpus cavernosum *Urethræ*, after venereal virulency, are very difficult to cure. Till the pocky matter is all extirpated, it is in vain to attempt the cure of these knots, and even then they do not yield to mercury in any shape, but are resolved by embrocations of the waters of Bareges. See Mem. de l'Acad. de Chirurg. Tom. 1.

Mr. le Cat has given us the figure of the canal of the *Urethra*, determined by solid injections. See Phil. Transf. N°. 460. Sect. 5. p. 684.

URETHRÆ *Depressor*, in anatomy, a name given by Santorini to a muscle of the pudenda in women, the same with that which he calls in men the *elevator Urethræ* and *ejaculator*. Winslow, and the generality of the French anatomists, call it the *prostatique inferieur*. And Albinus, who has given to the *transversalis penis* the name of the *transversus perinæi*, calls this also the *transversus alter perinæi*.

URETHRÆ *Elevator*, in anatomy, a name given by Santorini to a muscle of the penis, which he calls also the *ejaculator*; it is called by Albinus the *transversalis alter perinæi*, to distinguish it from the muscle commonly called the *transversus penis*; but which he calls the *transversus perinæi*. The same muscle in women is called the *depressor Urethræ* by the same Santorini.

URETHRAM *Dilatans*, in anatomy, a name given by De Graef to a muscle of the penis called the *Urethram trahens* by Spigelius, and by the later writers, the *accelerator penis*. See the article ACCELERATOR.

URETHRAM *Trahens*, in anatomy, a name given by Spigelius and others to a muscle now generally called the *accelerator*. See the article ACCELERATOR.

URETHRÆ *Triangularis*, in anatomy, the name of a supposed muscle of the penis, called also *dilatator penis*, and *dilatator Urethræ*; it is properly only a process of the sphincter ani continued into the perinæum.

URIBACO, in zoology, the name of a Brasilian sea-fish, esteemed a very well tasted and wholsome one. It is somewhat of the figure of the pearch; its back is ridged, and its belly somewhat protuberant. It grows to ten or twelve inches long. Its teeth are small and sharp, and the ends of its gills terminate in a triangular point. Its gill-fins end in a triangular

triangular point; its belly-fins are sustained by a very rigid and strong spine. Its long fin, behind the anus, is all the way supported by flexile and short spines, and has one very strong and rigid one before it; and it has only one fin on the back, which reaches nearly to the tail, and is all the way of an equal breadth, and supported by rigid and prickly rays. Its tail is very deeply forked. Its scales are all of a fine silvery white, with some faint cast of a pale but bright red; its belly-fins are white, and its back-fin and tail are reddish. Its side-lines are broad, and of a fine red; and over these, and under them, near the tail, there is on each side a large black spot. *Marggrave's* Hist. Brasil. *Ray's* Ichthyogr. p. 338.

URINARIA, in botany, a name given by some authors to the common dandelion. *Ger.* Emac. Ind. 2.

URINE (*Cycl.*)—The secretion of *Urine*, as also that of perspiration, is considerably influenced by the passions. See the article PERSPIRATION.

Dr. Rega mentions the opinion of some modern authors, who imagine that our drink passes through the coats of the stomach and bladder, *&c.* when it is so quickly evacuated by *Urine*, as it is observed to be after drinking several mineral waters and other liquors. He endeavours to prove, by an easy calculation of the quantity of *Urine* secreted in the kidneys, that they are capable of furnishing all the quantity observed at any time. And lastly, he mentions the fullness and great frequency of the pulse, after drinking these liquors, as a proof of their being mixed with the blood. Med. Eff. Edinb.

The specific gravity of the human *Urine*, made in the night-time, has been found greater than that made in the day. Hence Dr. Bryan Robinson [b] infers, that *Urine* draws off more contents from the blood in sleep, than when bodies are awake; and consequently that natural sleep is a very good sign in fevers, in which the blood abounds more with contents than it does in health.—[[b] Of the Food and discharges of Human Bodies, p. 85.]

The *Urine* of phthisical people is said to be always specifically heavier than that of people in health, or in any other disease.

We have frequent instances of peoples voiding by *Urine* much greater quantities of liquids than they take into the stomach in the time; but this, though a seeming paradox, is easily explained, by considering how very small a part only of what we call solids, is really solid. Chemistry shews us that the far greater part of our food may be procured in a fluid form by distillation; and on this principle alone, so long as the quantity of *Urine* voided is not more than that of the meat and drink together, the miracle ceases. There are, however, instances of the quantity of *Urine* greatly exceeding that of both. Dr. Wittie, in this case, supposes the converting of air into water to make up the over-proportion; but it is more rationally accounted for by the decrease of the patient's flesh all the time. Our own bodies, as well as the foods we take in for their support, are composed of a greater proportion of fluids; and the real solid matter is so very little, that when, by the course of a disease, those fluids, which should remain locked up in the texture of the solids, and increase their bulk, are drained and separated from them, it is no wonder that the discharge be vastly disproportioned to the supplies, when the body itself goes off with them. We have indeed accounts not easily soluble on these principles, nor any way but by the scheme of converting air into water before-mentioned; but till we are certain that the quantities and proportions are accurately noted in them, it will be rash to conclude any thing from them.

Among accounts of this kind, we have these recorded in the Philosophical Transactions from Dr. Wittie and others. A person at Hull, in a diabetes, voided twenty-four pints of *Urine* every eight and forty hours, for many weeks together, during which time his muscular parts were all in a manner dissolved into *Urine*; and the weight of the *Urine*, voided in these weeks, according to the Doctor's computation, greatly exceeded the whole weight of his body, and of all that he had eaten or drank in the time. Sir Kenelm Digby tells us a thing, which, if we may credit it, calls for a supply greater than any thing but the converting a great part of the air taken-in in respiration could give: This is of a nun, who voided two hundred pints of water as from her bladder every twenty-four hours, for some weeks together. There is another relation of a sick maid in Italy, who voided thirty-six pints of *Urine* every twenty-four hours, for the space of sixty days, till at the length the whole quantity voided amounted to one thousand seven hundred and forty pounds; a weight greatly superior to that of her own body, and of all that had been received into it in the time. The whole credit of these relations lies on the character of their authors; and we are to remember, that the strongest of them comes from an author who, in another part of his works, has given a receipt for creation; a method, as he expresses it, of making live crawfish. Philos. Transf. N°. 52. See the articles SOLID and FLUID.

In order to the preparing the phosphorus, and indeed most of the other preparations of *Urine*, the first step is to reduce that liquor to the consistence of a rob or thick extract; those who have worked on this subject sufficiently know, how abominably nauseous and disagreeable a task this is. The operator alone is not the person who is almost poisoned by it, but the whole neighbourhood is affected; and it is well known, that our Godfrey, who used to prepare large quantities of this substance, was always obliged to keep a house in the fields to perform this part of the process in.

There is an easy and excellent method proposed by Stahl for the performing this troublesome business, by means of condensation by cold or freezing. There needs no more than to expose the proper quantity of *Urine* to some frosty nights in winter; or at any time of the year to our Ice-houses, or other places where ice is preserved all the year round. The frost will, in this case, affect a large part of the *Urine*, but not the whole; and the liquid part being separated from the solid ice, it will be found that the watery parts alone have suffered the freezing, and that all the unctuous and saline ones are left behind in the unfrozen part, which is, by repeated freezings of its yet remaining aqueous part, at length reduced to that sort of rob which is required for all the purposes of distillation, and that without any trouble or offensiveness, either to the operator or any body else. The power of condensation by freezing in this manner, extends to wine, vinegar, and all fermented liquors; but it operates differently on the several different ones, and is to be regulated according to their natures. The natural cold of our climate is seldom too great for any of the liquors we desire to condense; that is, it is never so great as to condense the whole into ice. It often is not sufficiently great to condense the aqueous part, even after ever so many repetitions. In this case, it may be proper to bring in the use of the common freezing mixtures, made with ice, or snow and salt. To suit the artificial degree of cold, in these cases, requires care and experience, and is almost as nice a point as the suiting the degrees of heat in the operations of chemistry. *Stahl* de Concentr. Vin. *Shaw's* Chemical Essays.

When *Urine* has been reduced to a rob by condensation by freezing, it is found to vary very remarkably, according as it was taken, either fresh, or half putrified, to make the operation. That which was made fresh remains in this state tolerably clear, and of a dull yellow colour, and almost without smell; but that which was taken half putrified, remains of a colour between brown and red, or somewhat deeper, like the brown strong beer, and becomes intolerably fœtid, if set for any time in a warm place; but that which was condensed fresh, is not liable to this accident, but may be kept two or three years in the state of rob, and will never grow fœtid, nor smell much like *Urine*. *Stahl* de Concentration.

Glauber has taught the world to believe, that there is nothing so destructive to vegetables of all kinds as *Urine*, which, he says, by means of the sal armoniac that it contains, burns up all the roots. This is certainly true of *Urine*, and of dung too, when laid on in too great quantities; but it is certain that *Urine* is as safe as dung, and as profitable, when laid on in a sparing and proper manner. Dung is of no use to land, but by its fermentation; but the best of all things to hasten and perfect that fermentation is *Urine*. The Dutch are perfectly sensible of this, and are as careful to preserve the *Urine* of their cattle as the dung. *Mortimer's* Husbandry.

Bloody URINE, *Mictus Cruentus*, in medicine, the name of a very troublesome and often dangerous disease; it is a voiding of pure blood by the urinary passages, and takes its origin from a congestion of blood in the emulgents, and is the method (tho' an unhappy one) taken by nature to discharge the load of a plethora, and give the mass of blood freer room to circulate. This is the natural or simple *Mictus Cruentus*; but, beside this, there is another accidental one, arising from an injury of the vessels from a rough stone in the kidney. This, however, is a much less frequent case than is vulgarly imagined; for there are great numbers of nephritic patients who have very large stones in the kidneys, yet void no blood, and in many cases, where this is a symptom, it will be more just to attribute it to the effect of the sharp nephritic medicines, than to the action of the stone.

Signs of it. When a *Mictus Cruentus* is natural, it usually comes on tacitly, and without any previous symptoms, or if there be any, they are only some sensations of a weight and pressure upon the loins: but when this is brought on by accidents, as by the rubbing of a stone, or the like, it is always preceded by violent pains. The blood voided with the *Urine* is florid, and, after a time, subsides perfectly from among it; but when there is an exulceration of the kidneys, the blood is altered in its texture and appearance, and shews itself like worms.

Persons most subject to it. These are old men of plethoric habits; but even with these it is a rare distemper. When young men, or even middle-aged ones, are affected with it, we are to seek for its origin in violent and preternatural causes. Men are also, in general, more subject to it than women; but these are not wholly free from it.

Causes of it. These are usually a plethora, and an unnatural derivation of the hæmorrhoidal blood to the kidneys, where the vessels burst; for it is very rarely, and never but from some preternatural causes, that they burst in the bladder. The common violent and preternatural causes of this disease, are the use of the hot diuretics, of balsam of sulphur, of oil of amber, and, above all, of cantharides. Long riding on horse-

horfeback, or blows on the region of the loins. In old men, an over ufe of venery may alfo bring it on, as alfo violent paffions of the mind, a fpirituous diet, an exulceration of, or a ftone in, the kidneys; and finally, an omiffion of habitual difcharges of blood, whether they have been artificial by bleeding, or natural by the hæmorrhoids, or the like.

Prognoftics from it. It is a diftemperature that never can prove of benefit in any cafe, but is often very dangerous. Old men who are afflicted with it, rarely live long after it, efpecially if the difcharges are not regularly made; and if it be rafhly fuppreffed by the ufe of aftringents, in any cafe, it brings on inflammations, fevers, and often dropfies. Ulcers in the kidneys are another very frequent effect of this; and under thefe, blood and purulent matter are voided together, and appear like clouds in the *Urine*.

Method of Cure. In the time of the fit, the violent emotion of the blood is to be reftrained by nitre, cinnabar, and fome of the abforbent powders, and if thefe are found infufficient, the milder aftringents are to be joined with them; coral, crocus martis, and vitriol of iron; and if thefe fail, the aftringent tinctures of fteel, and the terra Japonica, are to be given. Some alfo recommend as fpecifics, the juice of nettles, a decoction of the equifetum or horfe-tail, and a tea made of afparagus-roots. The bowels muft be kept gently open by clyfters, or the milder purgatives; and after the fit the fame methods are to be continued, to prevent a return. After this, bleeding in the foot is of great fervice, and old perfons are not to be excufed from it on account of their age. It is finally to be confidered, whether an obftruction of the menfes, or of the hæmorrhoidal difcharges, have occafioned the difeafe; and if fo, they are to be regulated with all due care for the future; and for the firft the proper medicines are to be given; for the latter, leeches are to be applied to the hæmorrhoidal veffels. *Junker's* Confp. Med. p. 39—44.

In cafes of *bloody Urine*, fpirit of vitriol, mixed with the patients drink, has been found ferviceable. See Medic. Eff. Edinb. abrig. vol. I. p. 68.

Incontinence of URINE. This is a term ufed by medical writers to exprefs an involuntary excretion of this liquor, whether it be inceffantly, or in larger quantities at different intervals.

This is of two kinds; in the one it is only in the night, in the time of fleep; and this arifes merely from carelefsnefs, and a bad habit; in the other, it depends on a paralytic affection of the fphincter of the bladder; and in this cafe it drops away continually from the patient; and this is therefore called by fome a *ftillicidium*.

Authors alfo divide an *incontinence of Urine* into the idiopathic and fymptomatic: The idiopathic is a difeafe in itfelf, and depends upon the preceding caufes; the fymptomatic happens to different perfons on different occafions, as a fymptom of other complaints. It is common to dying perfons; it is alfo very frequent to women who are very big with child, and fometimes happens from violent fneezing, coughing, or laughing.

Perfons fubject to it. The voiding of the *Urine* involuntarily, and in the fleep, in infants, is not to be accounted a difeafe; but when this cuftom continues with them as they grow up, from idlenefs, or ill habit, it is at length to be confidered as a difeafe, as they are by no means able to help it. Women who have fuffered much in child-birth are often fubject to an *incontinence of Urine* afterwards, efpecially perfons who have had their firft child at an advanced age. People in years, who are fubject to paralytic complaints, are alfo often afflicted with this troublefome complaint; and many who have been cut for the ftone by perfons not fufficiently fkilled in the operation. Perfons fubject to the piles alfo fometimes fall into it, from the fuppreffions of their ufual difcharges, and fometimes from the tumors becoming fiftulous, and reaching to the neck of the bladder. Impofthumes of the bladder will alfo occafion it, and violent external injuries.

Prognoftics in it. An *incontinence of Urine*, which happens only in the night, and is merely caufed by a bad habit, and not of long ftanding, ufually admits of a cure; but the ftillicidiums of *Urine*, from paralytic diforders of the fphincter of the bladder, are very rarely cured, efpecially when they have been fixed fome time upon the perfon.

Method of Cure. The involuntary voiding the *Urine* in the night, in children, is to be cured, in a great meafure, with punifhment for the neglect, and by denying them much liquids after dinner-time; by a proper diet; the avoiding all diuretics, and the making water immediately before going to bed; and when it has gone fo far, that the tone of the parts is injured, the ufual ftrengthening medicines are to be given, as in the following cafes.

When the *incontinence of Urine* is occafioned by a paralytic weaknefs of the fphincter, nervous and ftrengthening medicines are the proper method of curing; in this cafe, maftic, amber, nutmeg, and cinnabar, are found to be of great fervice, and pills or powders compounded of them, are an excellent general remedy to be given in fmall dofes, two or three times a day. Externally, it is very proper to ufe by way of fomentation, decoctions of rofemary, fage, ferpyllum, marjoram, and the like warm herbs in red wine.

When the difeafe is occafioned by an impofthume or ulcer in the neck of the bladder, balfamics are to be given, as maftic, gum juniper, and boiled turpentine; but when it is owing to injuries received in child-birth, the manual operation of the furgeon is ufually to be preferred to all internal medicines. *Junker's* Confp. Med. p. 538.

Suppreffion of URINE. See the article SUPPRESSION *of Urine*.

URINE *of a Cow.* This difagreeable potion having been much recommended as a medicine both in England and France, Mr. Lemery was at the pains of inquiring how far it might reafonably be fuppofed to poffefs the virtues afcribed to it.

He obferves, that *Urine* in general is a ferous liquor, impregnated with a volatile falt and oil, both which it has taken up from the blood, in the courfe of its circulation with it. It is eafy to conceive, that principles fo active as thefe may give it virtues, and thofe very great ones. We find that recent human *Urine* purges, when taken in a proper quantity; but for all medicinal purpofes, it muft be much more proper to take the *Urine* of fome animal which feeds only on vegetables, that being a fort of extract of the more fubtle faline parts of the herbs on which the creature feeds.

Tho' the *Urine* of any of thefe animals feems equally to be recommended; yet that of the cow has, in all times, been preferred to others, from the quantities of it eafily obtained, and the tame and pacific nature of the animal, which has been fuppofed fo far to influence it, as to occafion its *Urine* to be lefs acrid than in other beafts.

The fpring feafon is the propereft for the ufe of this remedy, and the method of taking it is to drink two or three large glaffes in a morning fafting, a quarter of an hour after one another: Thus taken, it purges both by ftool and *Urine*; the perfon is to walk about, after taking it; and it has been found, in this manner, to do great fervice in jaundices, dropfies, rheumatifms, and afthmas, as alfo in fciaticas, and vapours.

Mr. Lemery gives feveral inftances of cures performed by it, under his own direction, and afterwards proceeds to give its analyfis.

This *Urine* is ufually fomewhat turbid, and when it has been fuffered to ftand by a little, depofits a fediment; it is of a pale yellow colour, and of a faint fmell, greatly different from the *Urine* of the generality of other animals, and refembling the fmell of the dung of the fame creature, only lefs ftrong, and with fome mixture of the fmell of new milk.

The tafte is faline, acrid, and bitter; cows kept in cities often have their *Urine* very acrid; but thofe in the fields frequently have it with only a flight bitternefs at firft, and not fhewing its faline or acrid properties till after it has been made fome hours. It always readily ferments with acids.

Mr. Lemery put into a cucurbit fixteen pounds of *Urine of a cow*, kept in the country, and which had been made two days; This being diftilled in a cucurbit, purged with lefs violence than before. The purging virtue plainly confifts in a volatile falt, which the *Urine* carries up with it in vapour; for it taftes fomewhat acrid and faline after diftillation.

The diftillation being continued in the ordinary way, there arifes a large quantity of volatile falt and oil, in nothing differing from thofe of the human *Urine*; and the remainder, in the bottom of the veffel is a black, light, and fpongy coal, weighing four ounces: this, being calcined in an unglazed earthen veffel, over an open fire, and treated in the common way of elixiviation, affords three ounces two drams and a half of a fixed acrid and highly alkaline falt, white, and without fmell. Mem. Acad. Par. 1707.

URN (*Cycl.*)—*Roman* URNS. Thefe veffels are frequent in many parts of this kingdom, where there have been Roman ftations, and are of very various kinds and manner of workmanfhip.

Dr. Lifter, who was very fortunate in his refearches into the ftructure and differences of thefe remains of antiquity, obferved, that in Yorkfhire, where there are great numbers found, there were met with three very different kinds, as to their matter and tempers.

1. A bluifh-grey fort, which had a great quantity of coarfe fand wrought in among the clay. 2. A fort of the fame bluifh colour, but containing a fand of a much finer kind, and full of mica, and probably made of a clay naturally fandy, or a fine fmooth and ftiff loam. And 3. A red fort, made of a fine pure clay, with little or no mixture of fand. Thefe are throughout of a fine red colour like bole, and many of them are elegantly adorned with figures in *baffo relievo*; and ufually thefe have on the bottom, or elfe on the cover, the name of the workman, which fome have miftaken for the name of the perfon whofe afhes they inclofe; but this muft be an error, fince great number of pots and urns are found with the fame name. Thefe are varnifhed all over, both infide and out, with a varnifh of a bright red colour.

The feveral matters of thefe *Urns* informed this ingenious inquirer of the place where they were made; which he found to

to be in the same county on sand-hills, now never used as potteries; but, as he well observes, the difference is very great between the potteries of those days and of ours, since we, who use great quantities of clay, and but little sand, erect these works where there is much clay, and bring the small quantity of sand we use to it; whereas the Romans, on the other hand, who used much sand and but little clay, naturally established their works where there was plenty of sand, and brought their clay to it.

The *Roman Urns* differ from the earthen-ware made at this time in several particulars: 1. They have no lead-glazing, which seems a modern invention, and is, in many respects a very bad one. See the article GLAZING. 2. They are composed of a far larger quantity of sand than clay. And 3. they are baked not in an open fire, as our common earthen-ware, but have been inclosed in large earthen vessels, to defend them from the immediate contact of the flames; and hence it is, that the natural colour of the clay they are made of is not altered in them.

The red *Urns* seem to have been the master-piece of the workmen, and to have employed their greatest art; the embossed work upon them is often very beautiful, and their coral-like glazing is more beautiful than any thing of the modern times, and seems to have been done by dipping them all over in some appropriated liquor, and afterwards baking them in the close manner before described. This has certainly been the method they used, since the fragments of these large coffins, or cases, are found near all the Roman potteries. *Hook*'s Philosophical Collections, p. 87.

The Romans, and most other nations, contented themselves to make their funeral *Urns* of potters ware, or baked earth; but we find there have been some people who have made them of gold, on particular occasions. In the year 1685, as a peasant of the island of Funen was ploughing a piece of land, which had before lain barren, he turned up no less than six golden sepulchral *Urns*. They were all full of a greyish substance, which some took to be a grey earth; but it was much more probably ashes.

These are all preserved at this time in the musæum of the king of Denmark at Copenhagen; the largest of them weighs two ounces and a half, and the others about two ounces and one dram each. Wormius, and some others, give accounts, that it was an antient custom among the northern nations to burn their dead, and when they were great persons, to collect their ashes and bury them in golden *Urns*; and the finding these seems an evident proof of the truth of that account.

These *Urns* were very thin, and each had three rings of gold about their necks, and several circles, one within another, with one common center carved on the outside round the body of the *Urn*. They held about five ounces of liquids apiece, or a little more than that; one near six ounces.

Sepulchral *Urns* of crystal were also not uncommon; the same musæum has some of these: they are of a conic figure, and have usually a gold wire wound round them. *Urns* of this kind have been found buried in some parts of Norway. Another kind of *Urns* were those which they called *lachrymales*, or the *tear-Urns*: These were contrived to receive the tears of the friends of the deceased, which were afterwards mingled with the ashes of the burnt corpse: These were made of various materials, and of various shapes and sizes, according to the fancy of particular people. Phil. Transf. N°. 285.

UROGALLUS, in zoology, the name of a bird of the gallinaceous kind, called also *tetrao*, and in English the *cock of the wood* or *mountain*. See Tab. of Birds, N°. 25.

In shape it resembles the turkey, and approaches to it in size. Its legs are feathered down to the toes before, and naked behind. Its breast is of a pale reddish brown; the ends of the feathers white; and the whole variegated with transverse black streaks. Its belly is greyish, and its back elegantly variegated with black, reddish-brown, and grey. The ends of the feathers are all spotted with small specks, unless on the head, where they are of a fine plain black; but with a glow of purple intermixed. The tail is of a reddish brown, variegated with transverse black streaks, and is white at the tip or end. It is common on the Alps, and in some parts of Italy, and is said to be found also in the mountainous parts of Ireland. Its flesh is very delicate.

UROGALLUS *Minor*, in zoology, the name of a large bird common in some counties of England, and called the *black game*, or *grouse*, and by some authors, *tetrao minor*. *Ray*'s Ornithology, p. 123. See Tab. of Birds, N°. 26. and the article GROUSE.

UROMASTIX, in zoology, a name used by some authors for that sort of lizzard called *cordylus*. *Grew*'s Muf. p. 45. See the article CORDYLUS.

VROW-*Fish*, in zoology, the name of a fresh-water fish of the malacostomous kind, or, as we call it, the leather-mouthed kind, caught in the lakes and rivers of Germany, and esteemed a very delicate fish.

It is something like the English rudd or finscale, but its body is somewhat longer, in proportion to its breadth; its back is brown, and its belly yellow; the belly-fins near the anus are a little reddish, but all the rest are brown; the scales are large and silvery, and the irises of the eyes have each, in their lower part, a blood-coloured spot; the tail is forked; and its usual size is about seven or eight inches, though it is sometimes caught considerably larger. *Willughby*'s Hist. Pisc. p. 253.

URRY, in natural history, a name given by the people of Cheshire, and some other counties of England, to a black fat earth found in coal pits, lying immediately over the stratum of coal. It is found to be an excellent manure for land, particularly in cold clayey soils. *Mortimer*'s Husbandry.

URSUB, a name by which some of the chemical writers have called lead.

URTICA, *Nettle*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the apetalous kind, being composed only of a number of stamina placed in a cup. These are barren, and the seeds grow on other plants of the same species, which have no flowers, and are contained either in round globules, or bivalve capsules, or in long tufts.

The species of *Nettle*, enumerated by Mr. Tournefort, are these: 1. The great stinging *Nettle*. 2. The great stinging *Nettle*, with red stalks. 3. The common less sharp *Nettle*. 4. The common small *Nettle*. 5. The stinging *Nettle*, with round balls, and seeds shaped like linseed. 6. The pellitory-leaved *Nettle*, with round balls. 7. The great Canada racemose *Nettle*. 8. The Canada *Nettle*, with leaves like the myrrhis. And 9. The racemose American *Nettle*, with large hazel-like leaves. *Tourn.* Inst. p. 334.

The roots of the common *Nettle* are much recommended in medicine; they are powerful diuretics, and are said to have great virtues against the stone and gravel. They cleanse the blood, and are said to be of great service in hæmorrhages of all kinds, particularly in spittings of blood, and overflowings of the menses. Authors add to this, that they are specifics, by way of antidote against the poison of henbane and hemlock; but this we are not so well assured of. The young shoots of the plant are eaten in the spring, as good against scorbutic complaints. *Dale*, Pharm.

The antients seem to have despised this plant, from its being common, and, though possessed of great virtues in medicine, neither the Greeks nor Latins have said much about it; nor have the Arabians, who abound in the imaginary virtues of plants, thought the real ones of this herb worth their consideration.

It has, however, been more honoured lately, and notwithstanding its being now the most vile and abject plant among us, as well as the least regarded by the antients, Johannes Francus, an author of considerable fame, has published a treatise solely upon it; in this he has treated at large on its history and virtues. He describes its stings in a very judicious manner, according to the present doctrine of the microscope, and gives the history of certain worms of singular kinds which feed upon it; and adds its use in our own foods as a wholesome and agreeable pot-herb; in our drink as a substitute for hops, being as well capable of preserving it as those, and its great service to the farmer in fattening hens.

John Melchiore Dreschler, in the year 1717, sustained also a thesis on the virtues and uses of this plant, which has been since printed, ornamented with several cuts. In these two authors we find the whole account of the several uses this common plant has been put to, and may be put to in our manufactures, our domestick and medicinal uses; and, if what they say be true, we must wonder to see so much value overlooked in an herb, only because it is common.

URTICA *Errans*, in zoology, the name of a sea-animal, of the nature of the common *Urtica marina* in many particulars; but as that is always fixed down to the rocks, this species is always found loose.

It has been supposed that these creatures affected the skin with a pain like that of the stinging of nettles on touching them, and even the eyes of those who only look attentively on them; but Mr. Reaumur, who saw prodigious numbers of them on the coasts of Poictou, declares that he found no such property in any of them, any more than in those fixed to the rocks.

These in substance so much resemble a stiff jelly, that if they were called sea-jellies, there would want but a short additional description to make them understood. Their flesh, if it may be so called, appears of the colour as well as the consistence of a common jelly; and if a piece of one of them be taken up, the mere heat of the hand is sufficient to make it melt away into plain water. These are notwithstanding true and perfect animals; and those who have been of a contrary opinion, have not examined them with sufficient attention. There are very different figures among them; but this is owing to their being of different species, for all those of the same species are ever exactly of the same figure. One great reason of people's supposing them unorganized bodies, is, that what is seen of them about the shores is very often a fragment of a dead animal, not the whole of a living one; and no wonder if all the

neceſſary parts of an animal could not be found in ſuch a piece of one

Though the generality of theſe animals are of the ſimple colour of a jelly, there are ſome of a greeniſh caſt, and others which have a broad band of a beautiful purple round their extremity; and ſome are beautifully ſpotted with brown. Their figure is very well expreſſed by that of the head of a large muſhroom; their upper ſurface is convex in the ſame manner, and this convexity is greater or leſs in the different kinds, as it is in the different ſpecies of muſhrooms; all that is to be obſerved on this convex ſurface, is, that it has ſeveral little protuberances on it, ſhaped like ſo many nipples, and placed in an irregular manner: theſe are of the ſame colour with the reſt of the body; but though there is nothing more to be ſeen on this ſurface, the under, or concave one, gives proof enough of a regularly organized body. The edge is very thin, and cut in ſeveral places; and juſt within that there appears a great number of concentric circles, which cover the reſt of the ſurface. Theſe are not all complete; however, thoſe which are near the center, are divided into ſixteen arcs, and thoſe more diſtant into eight. Theſe ſeparations in the circles are made by certain tubes, which are always full of water, which they can, at pleaſure of the animal, communicate to other very ſmall and fine tubes, placed between the circumferences of ſome two of the circles. Theſe ſmall tubes are of great conſequence to the well-being of the animal, and they are known to be tubes by their figure, when full, and are eaſily proved to have communication with theſe other reſervoirs, by the preſſing the larger, which always ſends the water into theſe ſmaller ones. The large veſſels, which go from the center to the circumference, and theſe ſmall circular ones ſeem, in ſome meaſure, to reſemble in their office the veſſels of larger animal bodies; and this water contained within them, to be a liquor elaborated there, and analogous to blood, which fills out and diſtends the very fine and ſmall ſolid parts, of which this animal's body is compoſed. If one of theſe animals be dried in the ſun in hot weather, there remains nothing of it but a ſubſtance like a thin parchment; but if one of them be boiled in water, it does not diſſolve away as might have been expected, but only regularly decreaſes in ſize; and when it has become of about one fourth of its natural bigneſs, it there ſtops the decreaſe, and continues nearly of that ſize, and after that will not melt away upon the hand.

Near the end of the ſtrait tubes, all the animals of this ſpecies are divided into four parts, by four bands or columns, for they are round in ſome, and flat in others. Theſe are ſometimes raiſed almoſt perpendicularly on the baſe; ſometimes they make an acute angle, and they all join at length to a round trunk of about their own length; this trunk is of a cylindric figure, and is divided into eight branches. In the ſpace contained under the four columns, there is a large canal formed by a thick membrane, which ſeems the only ſolid ſubſtance in the animal; this membrane is folded into a ſort of purſe, and forms a ſort of canal, which becoming round near the baſe of the columns, takes the ſame figure which a ribband would have, if turned round the four arms of a large and regularly ſhaped croſs. This large canal is full of a yellowiſh glutinous liquor, and it uſually gives one or two branches to each of the columns. Theſe four columns terminate, as before obſerved, in a trunk, which then divides into eight branches, and their route may be further traced through the whole body of the animal, as they contain the ſame yellowiſh liquor with this large veſſel, which is every where diſtinctly ſeen, as being very different from the reſt of the body in colour.

All the creatures of this ſpecies, which we ſee thrown upon the ſhores, are found lifeleſs and without motion; but there is nothing wonderful in that, becauſe the violent ſhocks and blows which they muſt have received, in being daſhed againſt the rocks or ſands by the waves, are enough to kill ſo tender an animal. One proof that theſe animals once lived, is, that all thoſe which we find about the ſhores are heavier than the water, and ſink to the bottom, whereas all thoſe ſeen out at ſea, ſwim upon the ſurface; and this could not be the caſe in regard to any ſubſtance heavier than water, unleſs kept up by ſome voluntary motion. This motion Mr. Reaumur has obſerved to be a reciprocal contraction and dilatation of the whole body, in the manner of a ſyſtole and diaſtole. In the contraction it elevates the convexity of the body, and in the dilatation it makes it more flat, and by continually repeating theſe motions, it keeps above water as a man does by ſwimming. Mem. Acad. Par. 1710.

URTICA *Marina*, the *Sea-Nettle*, in botany. See the articles LAMIUM and ARCHANGEL.

URTICA *Marina*, in zoology, the name of a remarkable genus of fiſhes, ſo called from their affecting the ſkin on touching them, with a painful ſenſation like that of the ſtinging of nettles. Theſe are an animal of the loweſt claſs, and have by many been reckoned among thoſe creatures called *zoophytes*, or plant animals, as ſuppoſed to partake of the nature of vegetables and of animals. Some of the ſpecies of this fiſh are found looſe upon the ſmooth ſhores, and ſome fixed to the rocks which are always covered with water. This has given birth to a diſtinction of them into two claſſes, which is as old as Ariſtotle; thoſe of the one being ſuch as move in the open ſea, and thoſe of the others ſuch as are fixed to rocks, and were ſuppoſed always to remain immoveably in the ſame place. The accurate Mr. Reaumur has obſerved, however, that even theſe laſt have a power of a progreſſive motion, and are not doomed to an eternal reſidence on the ſame ſpot. The motion of theſe creatures is ſo ſlow, that it might eaſily paſs unobſerved by leſs accurate obſervers; this gentleman comparing it to that of the hour-hand of a clock, and adding, that a journey of an inch takes them up commonly between one and two hours. He obſerves alſo, that many of the ſpecies have no property of ſtinging, or cauſing any painful ſenſation on the fleſh. Ariſtotle and Pliny, who were both inclined to make theſe creatures of a middle nature between plants and animals, yet differ in their accounts of them; the former affirming that they have no anus or exit for their excrements, and the other allowing them an extremely fine tube or pipe for that purpoſe. What Pliny ſeems to mean by this pipe, muſt be one of the horns of the creature; but the matter it diſcharges from that, has nothing of the appearance of excrements, being mere clean water. Senſation, a power of eating and digeſting food, and locomotion, being certainly ſufficient characters of animal life, and this creature being evidently poſſeſſed of them all, there is no room to doubt its being as truly and properly an animal, as a whale or an elephant.

Theſe creatures occaſionally change their bodies into ſo many different forms, that there is no giving any deſcription of their figure. The moſt natural and general ſhape, ſeems that of a truncated cone, the baſe of which is applied to the rock; but this baſe is often round, often elliptic, and often of a perfectly irregular figure. This baſe is alſo ſometimes perpendicular to the ſummit; but very often it is oblique; and in changing the figure and extenſion of this, the animal alters its own whole ſhape at pleaſure; for the ſmaller this baſe is, the more elevated is the top; and, on the contrary, the broader it is, the flatter and lower is the whole fiſh. The ſurface of the top of the cone is not flat, but convex, and has in its center an aperture, which the creature makes larger or ſmaller at pleaſure. In ſome poſitions the whole fiſh not unaptly reſembles a purſe, only with this difference, that the body is not drawn up into any folds or wrinkles by the cloſing the aperture or mouth. In the middle of this purſe, as we call it, is placed the body of the fiſh, touching this outer covering at the bottom on every ſide, and of a conic figure, as that is. At its top, however, it is looſe, and ſtands every way free from its covering; the ſides are more or leſs diſtant from this free or looſe part of the body, as the aperture at the top of the cone is more or leſs open; when it is nearly ſhut up, very little of the body of the animal can be ſeen; but when it opens it to different widths, more or leſs of the body becomes viſible, and when it is at the wideſt, every part of it, and all the horns, are ſeen perfectly diſtinct. Theſe horns reſemble in appearance thoſe of the common ſnail; but in their uſe they ſeem much more allied to the pipes or proboſcides of the chamæ kind, the fiſh generally throwing out water at them on being touched. They are placed in three ranges on the internal ſurface of the covering, and are very numerous, their whole number not being leſs than 150.

The creature very often not only opens the outer covering or purſe to the utmoſt width it is capable of, but at the ſame time turns back its extremities; in this caſe the internal part, or body of the fiſh, becomes viſible on the ſurface, and at the ſame time all the horns being, by this bending back of the ſkin on which they grow, thrown into the poſture of ſo many rays; the whole makes a very remarkable figure, and not unaptly reſembles an anemony, or ſome other ſuch flower, when fully open. Very often alſo there is a great addition to the beauty of this appearance, by ſeveral round veſicles of water, which appear blue, or of ſome other lively colour. The general colour of the different ſpecies of this fiſh, or indeed of the ſame ſpecies in different circumſtances, is as variable as the ſhape; ſometimes they are ſeen pellucid and colourleſs, ſometimes white, often yellowiſh, ſometimes of a roſe colour; at other times they are of a beautiful green, and often of various ſhades of brown. In ſome theſe colours are equally diffuſed through every part; in others they are only ſeen in form of ſpots and clouds or variegations; ſometimes theſe are irregularly diſpoſed, ſometimes more regularly; but always with great beauty. The green ones have uſually a broad line of blue all round their baſe. The colours nor ſhapes of theſe animals can be no marks of different ſpecies; but the firmneſs of their fleſh may; in this they remarkably differ one from another, and this is a difference the more obvious, as their fleſh is always open to the touch, there being no ſhell, nor any other hard ſubſtance to cover it.

However ſlow the progreſſive motion of this fiſh is, when examined it is found to depend on a very remarkable mechaniſm, to underſtand which we muſt attentively conſider what is obvious to the eye in the ſtructure of the creature, and remember the compariſon of the whole fiſh to a purſe. We find that what reſembles the bottom of that purſe is flat, and is fixed to the rock, while the body of the fiſh is

contained

contained in the reft of the purfe, but never fills it, unlefs when the mouth of the purfe or covering is clofe drawn together. The whole covering is a collection of mufcles which are all tubular. The bafe of the fifh never appears to us, becaufe always fixed down to the rock; but when the creature is raifed from that pofition, and the bafe examined, it appears compofed of a vaft number of tubes placed one behind another, and running from the center to the circumference. Thefe tubes are often filled with an aqueous liquor, which may be forced out on preffing them. Befides thefe tubes, there are alfo to be feen many circular ones, which furround one another, and have for their common center that of the bafe. The conic part of the covering is in the fame manner compofed of a number of circular tubes, which are placed very clofe to one another, and all run parallel with the round verge of the bafe, and terminate at the upper circle or rim of the cone. Under thefe there is another feries of ftrait tubes, which all run from the bafe to the top of the cone. It is remarkable that the circular and ftrait mufcles are never feen together in the fame place; whether it be that the extending of the one fet makes the others flaccid, or only that the lefs extended ones are hid by thofe which are more fo. Sometimes there are only the circular ones vifible, fometimes only the ftrait ones, and often only a few of the circular ones appear, refembling fo many bands, between which it is eafy to fee the parts of the ftrait ones which lie under them. The creature feems capable of making all thefe changes at pleafure, filling fuch as it will with an aqueous liquor, which is the caufe of their becoming more vifible, and which is let out, if they are pricked with the point of a pin. The inflation of different parts of thefe ranges of ftrait and circular tubes, is what makes all the differences in the fhape of the fifh, and ferves alfo to the purpofe of its progreffive motion; and it feems probable that the aqueous liquor which ferves to diftend them, is, at the pleafure of the creature, conveyed to them from the horns, and from them back to the horns again. The progreffive motion feems thus performed: When the creature has determined which way it will march, it diftends all thofe longitudinal tubes which are on that fide of its body which is placed toward the point it would move to; this, from its round fhape at the bafe, gives it an oblong one; that is, it throws the fore-part fomewhat forward upon the rock; and, at the fame time, if the longitudinal tubes on the oppofite fide of the body be all left empty, and the circular ones diftended, thefe naturally draw the whole body toward the fore-part, and thus a fmall advance is made and preferved, and this, often repeated, is the flow progreffion of this animal. All this is, however, performed fo very flowly, that though there is a continual change going on in the creature, both as to fhape and place, yet if the eye is kept continually on the object, neither is perceived; but, if taken off for fome time, and the place and figure both kept in mind, both will be found to be altered on viewing again.

There is a fpecies of this fifh alfo which moves by means of its horns; this is known from the reft by the length of the horns, and their being covered with a glutinous moifture. This fpecies lives in the cavities and holes of rocks; and when it has a mind to move, it turns itfelf bottom upwards, and crawls flowly on by means of its horns, which then touch the rock.

The food of the *Urtica-marina* is not lefs wonderful than its ftructure and motions. It fhould feem very ftrange that an animal, foft like this creature, with no feet, no inftrument of that kind to help itfelf with, fhould be able to feed on the flefh of mufcles, fea-fnails, and other fhell-fifh; yet thefe are its conftant food. They find means to take in the fhell-fifh whole into the body, and then clofe the aperture faft upon it, fo that it is not to be feen that they have any fuch thing within them; they keep them here as long as they pleafe, and afterwards throw out the empty fhells by the fame aperture, which they can, as before obferved, widen and contract at pleafure. By what means the *Urtica* is able to get out the body of thefe fifh, is not known, as it all paffes in the body; but it very often fails, and the creature is obliged to throw out the fhell fifh alive again; and fometimes, when it has greedily gorged too large a morfel, and it is got into a wrong pofition to be thrown out the fame way, it is obliged to let it through the bafe, where there is no natural aperture, and where its paffage muft be attended with a terrible wound. The manner in which the larger fhells are thrown out by the mouth, is by opening it extremely wide, and turning it back, fo that the infide appears outward for a little way down; and this motion is alfo ufed on another very neceffary occafion, the excluding the young ones, for thefe animals are viviparous. Mem. Acad. Par. 1710.

It has been found that this creature has the remarkable property of the polype, in re-producing fuch parts as it had loft. Mr. Reaumur tried many experiments on the various fpecies of this, and of the ftar-fifh kind, and found that whatever parts were cut off, the wound foon healed; and Mr. de Villars had opportunities of watching the whole progrefs of the growth of the animals afterwards, and found that they not only feemed alive and well after cutting, their wounds foon cicatrifing, but that they, in a very little time, regained what had been cut off, and became as perfect as before.

URUS, in natural hiftory, the name of a fpecies of wild bull, of a very remarkable fize and ftrength. Cæfar, in his commentaries, has defcribed them as little inferior to elephants in fize, and refembling the bull in fhape, figure, and colour. He adds, that they were very fwift and fierce, and had horns very much larger, and very different from thofe of the common bull. And Mentzelius tells us, that it is a vaft and terrible fpecies of wild bull, common in Livonia, *&c.* and that when killed, its brain is found fcented like mufk. Mr. Ray wifhes very much, that fome one, who has an opportunity of feeing this creature, would give a more accurate and perfect account than thofe we already have of it. *Ray*'s Syn. Quad p. 70.

USNEA, (*Cycl.*) in botany, the name of a genus of moffes, the characters of which are thefe: They are wholly deftitute of leaves, and are compofed only of long flender filaments or ftalks, which are ufually folid, rigid, and of a cylindric figure. The extremities, or other parts of thefe, are at times furnifhed with a fort of orbicular bodies, dry and deftitute of ufe, but feeming to fupply the place of flowers. Thefe are hollow, in form of cups, but have no rim. The whole plants are fixed in the manner of miffetoe to the barks of trees. Micheli has given accounts of flowers and feeds in thefe plants; but Dillenius fufpects the accuracy of the obfervation, and adds, that if there are fuch, they are too minute to be of any fervice in the general diftinctions of the plants. *Dillen.* Hift. Mufc. p. 68.

Of this genus of plants there are nineteen known fpecies. 1. The ftringy-tree mofs, or common *Ufnea* of the fhops. This confifts of long and varioufly implicated threads, which are branched out into feveral divifions; this grows on old oaks, and other trees, in thick woods. 2. The wide-forked tree *Ufnea*, with finer points, defcribed by Micheli, and in its feveral varieties, by him called of three fpecies. It is compofed of thicker branches than the former, and they are only dichotomoufly divided, having no fmall branches but at the points or ends. 3. The wide forked *Ufnea*, with thicker points; this and the two former are of a grey colour, and this compofed of rough rufhy branches. It grows on old fir-trees. 4. The capillaceous knotty tree *Ufnea*, called the *long beaded Ufnea*, or *necklace mofs*. This is of a bluifh-grey colour, and hangs down from the branches of old trees. 5. The flat Alpine *Ufnea*. This is fofter than the others, and has long and flatted branches, and commonly is found on the larch-tree. 6. The beard *Ufnea*. This is compofed of thin and fibrous branches, and is ufually more or lefs knotty. It is of a pale grey colour, and grows on old beech, and other trees. 7. The black mane *Ufnea*. This grows in great plenty in the Hartz Foreft, and in fome parts of England. It is rigid, and of a rufty black. 8. The black, hard, woolly *Ufnea*. This grows on rocks and ftones, and refembles flocks of black wool, but is more rigid. 9. The black tufted *Ufnea*. This alfo grows on ftones; it is fmall and flender, but ufually ftands in thick tufts. 10. The hard and rigid tree *Ufnea*, with branches expanded every way. This is of a greenifh grey, and grows on oaks, and fometimes on rotten pofts and old boards. 11. The horfehair *Ufnea*. This is black, and compofed of flender filaments, fcarce at all branched, refembling horfe-hairs. It is common on the barks of trees in Patagonia. 12. The common fmall *Ufnea*, without rundles or cups. This is a very common mofs on old trees and boards; it is very much branched, and does not hang in long ftrings, like the others, but is of a fomewhat fhrubby appearance. 13. The common fmaller *Ufnea* with rundles. This is not lefs common than the former, and much refembles it; but the lateral branches are more rigid. 14. The true *Ufnea* of the Arabian phyficians. This is of a whitifh colour and fmooth furface, and is divided in the manner of a ftag's horns, and of a very agreeable fmell. The branches are partly cylindric, but a little compreffed, and are ufually crooked, and divided into many filaments. It is not a native of England, but is very common in the Eaft Indies, and in many other parts of the world. Bellonius fays, that it is commonly fold in Conftantinople. 15. The orange-coloured forked *Ufnea*. This is of a deep yellow, and confifts of flatted branches, dichotomoufly divided, and terminating in fine flender filaments. It is often found of a foot in length, and is common in the Canaries. 16. The brafs wire *Ufnea*. This is of a fine gold yellow; its branches are cylindric and rigid, and it grows up in the form of a fmall fhrub. 17. The fmaller yellowifh tree *Ufnea*, with coronated rundles. This is fmaller, and of a paler yellow than the other, and its branches are thicker. 18. The fmall hairy black *Ufnea*. This grows on ftones and rocks, and is very fhort and rigid. 19. The fmalleft of all the *Ufneas*. This is of a black colour, and grows on the barks of old trees, but is fo fmall as to be fcarce vifible. *Dillen.* Hift. Mufc. p. 70.

USNEN, in botany, a name given by Avifenna and Serapion to the plant Kali, of which the alkali falt called *pot-afhes*, and ufed in the compounding our foap, is made. There are alfo feveral other things called by this name, and, in general, all that were

were used in the scouring or cleaning of clothes. The dung of sparrows was used by some people for this purpose, as the dung of hogs is at this time, and this was therefore called by some *Usnen*. Hyssop, a plant famous for its cleansing virtue, was also called by the same name; and some have also applied it to the soldanella, or sea bind-weed.

Wherever, in the Arabian writers, the word *Usnen* is used in any of these latter senses, there is something added to distinguish which of the things before expressed is meant by it; but whenever it stands alone and unexplained, it is to be understood as meaning the *kali*.

USSAC, in the materia medica of the Arabians, a name given by Serapio to the gum ammoniacum of the Greek writers. It seems no other than a false spelling of the word *assac*, which is the common name of the gum in Avisenna, and other of the writers of that nation; but this does not seem to be the same drug which we call gum ammoniacum at this time.

USTRINA, among the Romans, the place where they burnt the bodies of the dead. It was commonly in the Campus Martius, or some other place in the suburbs, and sometimes in the city for persons of quality; and for the common people on the Esquiline mount. *Danet.* in voc. See the article Bustum.

USTULATION, *Ustulatio*, a word used by pharmaceutic writers to express the roasting or torrefying of humid or moist substances over a gentle fire, so as to render them fit for powdering. The same word is also used by some for what we call burning of wine.

UTAMANIA, in zoology, the name of a bird of the web-footed kind, wanting the hinder toe. It is common about the island of Crete, and is very expert at diving. It is of the size of a teal, and has its head and back black, and its belly white. Its feathers are soft and slender, and rather resemble down than plumage; but they are very firmly affixed to the skin. Its beak is sharp at the edges, and is covered in a great part with down. Bellonius, who describes the bird, supposes it to be the only web-footed one that wants the hinder toe; but in this he is mistaken: his description and figure comes also so near the common beak or razor-bill, that it is pretty certain the bird is nearly allied to that, if at all essentially different. *Bellonius* de Avib. *Aldrovand.* de Avib. T. 3. p. 240.

UTAS, *Octava*, in our statutes, the eighth day following any feast or term; as the *Utas of St. Michael*, &c. And any day between the feast and the octave is said to be within the *Utas*. The use of this is in the return of writs, as appears by Stat 51 Hen 3. *Blount*, *Cowel.*

UTERINE (*Cycl.*)—Uterine *Hæmorrhages*. In this dangerous disorder the styptic powder of Helvetius is much recommended: and the stybium ceratum has also been tried with great success. See the articles Styptic *Powders* and Vitrum *Antimonii Ceratum.*

UTERINUS *Lapis*, in natural history, a name given by some authors to a stone found in New Spain, and in some other parts of America; it is very hard and heavy, of a beautiful black, and capable of a very elegant polish. The natives cut it into various shapes, and apply it to the navel in diseases of the womb, and pretend that it possesses very great virtues.

UTERUS (*Cycl.*)—Authors have differed as to the thickness of the *Uterus* of a woman with child. In an account of a dissection of a woman dead in labour, mentioned in the Medical Essays, vol. 4. art. 33, it is said, the *Uterus* was found at least half an inch thick in the thinnest part, and a good deal more at the fundus.

Uterus *of Fishes.*—Among the fish kinds, all those which are oviparous have no *Uterus*; but, on the contrary, all the viviparous fishes have this part. The whales, and all the cetaceous kinds, as also many of the cartilaginous ones, have the *Uterus* very fair. It is probable that the eel kind also have it; but this is less certain, the generation of those fishes being yet somewhat obscure. The *Uterus* in the cetaceous fishes is always divided into two processes or horns; but in the cartilaginous ones it is divided into two glandulous bodies, which are pervious, and, according to the opinion of Needham, discharge a whitish liquor into the womb, and are of great use in gravidation.

UTFANGTHEF, in our old law-books. See the article Outfangthef, *Cycl.*

UT Queant Laxis, *&c.* in antient modern music, a hymn to *St. John the Baptist*, composed about the year 770, in the time of Charlemagne, according to Possevin, by Paulus Diaconus of Aquileia. It is very famous in music, because the syllables whereby the musical sounds are distinguished, were taken by Guido Aretine from the first strophe thereof.

UTRAQUISTÆ, in church history, an appellation given by way of reproach, to those in Bohemia who communicate under both species, bread and wine. *Hofm.* Lex Univ. in voc.

UTRICULARIA, in botany, the name of a plant used by Linnæus for what other authors have called *lentibularia*, or hooded water milfoil. This, in his system of botany, is also a distinct genus of plants, the characters of which are, that the cup is a two-leaved perianthium; its leaves being very small, of an oval figure, hollow, and falling with the flower. The flower is labiated, and consists of one petal; the upper lip is plain, obtuse, and erect; the lower is large, plain, and undivided; between the two there is a heart-fashioned palate, standing a little out; the nectarium is corniculated, is shorter than the petal, and is produced from its base. The stamina are two short and crooked filaments; the antheræ are small, and cohere together; the pistillum has a round germen, a thread-like style of the length of the cup, and a conic stigma. The fruit is a large conic capsule, containing only one cavity. The seeds are very numerous.

UTRICULI *Foliorum*, a name given by the writers on the anatomy of plants to a number of small and fine vessels, which fill up the interstices between the several ramifications of the surculi, or minutest divisions of the branches of the middle rib.

These are to be examined by good microscopes, in order to obtain any idea of their structure. This is found to be composed of a reticular plexus of fine white and flat filaments, whose interstices are again filled up with other smaller *Utriculi*; so that nature seems but forming new bodies, by making congeries of the same, but in a more minute state. When the largest of these are opened by a fine instrument, they are found to consist only of a white skin, containing a greenish matter, composed of particles so fine, that the best glasses are used in vain to distinguish their figure.

Accident sometimes offers what all the art in the world would attempt in vain; and the leaves of trees, whose cuticle has been eat off on one side by small insects, sometimes afford views of these *Utriculi*, which no art could have laid open in so nice a manner, or in such various views. Act. Erudit. Ann. 1722. p. 28.

UVA, *Grape*. See the article Grape.

Uva *Gruina*, in the materia medica, the name of the fruit of the great American *vitis idæa*, or crane-berries. *Dale*, Pharm. p. 173.

Uva *Lupina*, *Wolf-Berries*, in botany, a name given by some authors to the common water-elder, and by others to the *herba Paris*, or herb true-love. *Ger.* Emac. Ind. 2.

Uva *Marina*, in botany, the name given by many authors to the *ephedra*, the sea-grape, or shrub sea horse-tail. *J. Bauhin.* vol. 1. p. 406.

Uva *Quercus*, in natural history, a name given to certain accidental productions of the oak, a tree famous for producing many such, beside its common fruit: The best account we have of this in particular, is from Mr. Marchant. He observed a vast quantity of this production upon an oak of about twelve foot high; this tree had no acorns, but there hung from almost all the branches a great number of greyish threads, of two inches or more in length, and of a silky flexible matter; to several parts of these there were fixed certain round red berries, sometimes two or three, sometimes ten or twelve on a thread; these were of the size of a half-ripe red gooseberry, but they had no umbilicus, nor any appearance of fibres; they were hard, and not hollow, but filled with a cottony matter, very closely compacted. The threads on which these berries were produced all grew out of the alæ of the leaves, in the very places where the beds for the rudiments of young branches should have come; and over these filaments there were often a few small leaves, of the regular shape of the oak-leaf.

It is generally asserted, that there are eggs of insects lodged in all these extraordinary productions of the oak, which are supposed to be produced by a wrong derivation of the juices, occasioned by the puncture of the fly which leaves those eggs; but the most accurate search could not discover the least appearance of any animal remains in any part of these productions, neither in the berries, nor in the threads that support them.

There is another species of this remarkable production, differing from the former, by not having the long threads on which the berries of that are supported; this, however, has been confounded by the generality of naturalists under the same name, and of this Mr. Marchant has given an equally accurate description. In the month of October he observed a young oak of about six foot high, in a coppice-wood, in a very flourishing condition, very full of branches and leaves, but without fruit. The young branches of this oak were loaded with clusters of red berries, of the shape and size of common red gooseberries; they stood principally at or near the extremities of the branches, and were of a very polished and shining surface, and of a spongy and tender substance. They stood in clusters of three, four, and five together, and each grew immediately to the branch, without any pedicle; they had some appearance of fibres, but not the least mark of an umbilicus, as in the regular fruits. On opening these berries, they were found full of a mucilaginous and viscous juice, of a red colour, tolerably fluid, and having some fibres intermingled with it; the taste of this juice was acrid, and its smell disagreeable, and like that of rotten wood; but there appeared not in these, any more than in the other species, any

any the leaſt appearance of any thing belonging to an animal, no egg, no worm, no fly, nor indeed any foreign body of any ſort whatever.

Theſe berries, though ſo large and ſucculent, are but of a very ſhort duration, for Mr. Marchant going three days after he had ſeen them in the greateſt perfection, to gather ſome of them, with intent to try their juice on different liquors, found they were all become flaccid and withered; and returning again three days after this, they were ſo entirely periſhed and gone, that there remained only a few veſtiges of thin ſkins on the places where they had been fixed to the tree, and ſome few fallen ones among the buſhes, that grew under the tree; and upon inquiring of the people who lived thereabout, to know whether theſe berries were a regular annual production of the tree, they told him that they never remembered to have ſeen any thing of the kind before.

It may not be eaſy perhaps to account regularly for theſe fortuitous productions; for they ſeem merely of the nature of monſters among animals, and it may be allowed no improbable conjecture in regard to them, that the root of theſe ſmall trees having taken in more nouriſhment than they could circulate, when it came to load the tender extremities of the young branches, may have made its way through their laxer texture, and being retained yet in ſome of their membranes, may have ſwelled out more and more, by the addition of freſh matter, and finally have been maturated by the ſun's heat into theſe ſeemingly regular productions. Mem. Acad. Par. 1692.

Uva *Urſi*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the globoſe bell-ſhaped kind, conſiſting only of one leaf. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower. This finally becomes a round ſoft fruit or herry, containing little ſtony ſeeds, which are gibboſe on one ſide, and flat on the other.

There is only one known ſpecies of the *Uva Urſi*, which is the plant called by ſome *idæa radix*, and by others the *whortle-berry*, with thick, fleſhy, and, as it were, punctated leaves. *Tourn.* Inſt. p. 599.

Uva *Vulpis*, a name given by ſome authors to the common nightſhade. *Ger.* Emac. Ind. 2.

VUBARANA, in zoology, the name of a harengiform fiſh, caught in the American ſeas.

It reſembles in figure our river trout. Its body is very nearly of the ſame thickneſs all the way, but is elevated a little on the back, and ſomewhat ſlender juſt near the tail. It grows to a foot in length, and to ſix inches in thickneſs. Its head is ſmall, and pointed; its mouth not large, and having no teeth; and its tongue long. It has but one fin on the back, and its tail is long and forked. Its ſcales are very ſmall, and are diſpoſed ſo evenly, and laid ſo cloſely down, that it ſeems ſmooth to the touch. Its back is of a bluiſh white, and the reſt of its body appears either of an olive colour, or of a ſilvery white, according to the light in which it is viewed. The belly is ſomewhat flat, and perfectly white, and the coverings of the gills ſeem plates of ſilver, their whiteneſs and luſtre are ſo elegant. It is a very well taſted fiſh, and is generally dreſſed with the ſcales on, they being not offenſive in eating. *Marggrave*'s Hiſtory of Braſil.

UVEA (*Cycl.*)—Mr. Ferren demonſtrated to the academy of ſciences at Paris, the lymphatic veſſels of the *Uvea* of the human eye. Hiſt. de l'Acad. des Sciences, 1738.

VULCANALIA, among the Romans, a feſtival in honour of Vulcan, which was kept from the twenty-third to the twenty-ninth of Auguſt. On this occaſion the people uſed to throw animals into the fire. *Pitiſc.* in voc.

VULGAGO, a name given by ſome botanical authors to the aſarum or aſarabacca, whoſe leaves and root are uſed in medicine. *Ger.* Emac. Ind. 2.

VULNERARIA, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the papilionaceous kind, and from its cup, which is of a tubular form and turgid, there ariſes a piſtil, which finally becomes a ſhort pod, containing roundiſh ſeeds; and being contained in a membranaceous bladder, which was before the cup of the flower.

The ſpecies of *Vulneraria*, enumerated by Mr. Tournefort, are theſe: 1. The common yellow-flowered *Vulneraria*, called *kidney-vetch*, and *ladies finger*. 2. The white-flowered *Vulneraria*. 3. The purple-flowered *Vulneraria*. 4. The five-leaved *Vulneraria*, called by many the *bladder lotus*. *Tourn.* Inſt. p. 391.

VULPANSER, in zoology, a name given by ſome authors to the ſhell-drake, or burrow-duck, a very beautiful ſpecies of duck, common on ſome of our coaſts, and called by the generality of authors *tadoma*. See the article Tadoma.

VULPECULA, in ichthyology, a name given by Bellonius and Geſner to the fiſh called by the generality of authors *centrine*.

It is a ſpecies of the ſqualus, diſtinguiſhed by Artedi under the name of the *triangular-bodied ſqualus, with no pinna ani*. The Italians call this *peſce porco*. See the article Squalus.

VULPES, the *Fox*. This creature has been long famed for its cunning, and is plainly of the dog-kind.

It differs, however, from the common dog in the length, denſe diſpoſition, and ſoftneſs of its hairs, eſpecially thoſe about its tail, and in its ſmell, which is peculiarly rank and diſagreeable. Its uſual colour is a reddiſh tawney, though it is ſometimes found white, and ſometimes black. Its manner of digging itſelf a hole in the earth, is alſo a cuſtom wholly different from all the dog kind, and it is far from the tameneſs of that animal, being with difficulty made to loſe its fierceneſs. Its internal parts, in general, are very like thoſe of a dog. *Ray*'s Syn. Quad. p. 177.

Vulpes *Marina*, or *Alopecias*, in natural hiſtory, the name given by authors to a large fiſh, called the *ſea-fox* by us.

It is ſaid by many authors to have naturally the rank ſmell of the fox, and to be one of the worſt-taſted fiſhes in the world; but this does not appear to be true, on a ſtrict inquiry; for its ſmell ſeems very little different from that of other fiſhes, and its fleſh is well-taſted; ſo that theſe things ſeem only to have been ſaid, in order to ſtrengthen the reſemblance with the fox; a name which ſeems, upon the whole, to have been given it only from the length of its tail; and even that, though very long for a fiſh of this kind, has no reſemblance with the tail of a fox. The length of this fiſh is about nine foot, and its breadth, in the broadeſt part of the belly, fourteen inches. Its tail is nearly as long as the whole body beſide, and is of the ſhapé of a ſcythe, and is bent downwards. Near the origin of the tail, it has a ſingle fin below, and the ſpine is more moveable up and down in this part, than in any other; ſo that the tail is, by this means, eaſily elevated or depreſſed. It has two eminences on the back, one large one near the middle, and the other a ſmall one near the tail: And it has three fins on each ſide; the pair that ſtand near the head are large, and reſemble the wings of a bird; the others are ſmaller. The ſkin is ſmooth, and without ſcales; and the fins and eminences on the back are compoſed of a ſort of ribs, held together by a tough and ſtrong membrane. The tongue adheres inſeparably to the lower jaw, and is compoſed of a great number of bones, articulated together by a fleſhy ſubſtance of a fibroſe texture, and covered with a membrane beſet with ſeveral prominences, which make it feel very ſmooth when the hand is drawn from the point towards the root; but very rough when it is drawn the contrary way. Theſe prominences, when viewed by the microſcope, appear as pellucid as the fineſt cryſtal. Its throat and ſtomach are remarkably large; and authors ſay, that when in a fright it will ſwallow its young ones into its ſtomach, and afterwards caſt them up again when the danger is over. Others who ſpeak largely of its cunning, ſay, that when it has ſwallowed a bait at a hook, it will take in the whole line, till it comes to a weak place, where it can bite it aſunder. This is a tale very well calculated for the carrying on a reſemblance with the fox in cunning; but it is very ill adapted to this fiſh, which has no teeth with which it can bite any thing aſunder. The heart of this fiſh is remarkably ſmall, nothing larger than a hen's egg; it is alſo much of the ſame ſhape, and has no pericardium; but the aorta for a little way is covered with a membrane analogous to a pericardium. The head ſeems a mere lump of fleſh, being covered with muſcles, of which ſome are four inches thick; and though the head is ſo large, the ſkull is not bigger than a man's fiſt; it is thick, and is divided within into three cavities, each of which contains a ſmall quantity of a mucous matter mixed with blood; ſo that the fiſh ſeems ſcarce to have any brain at all, what little matter of it there is being quite ſoft, and having very few windings. The eyes are as large as thoſe of an ox, and are only hemiſpheric in figure, being flat before, ſo that they appear of a very ſingular ſhape. Mem. pour Hiſt. Anim. p. 114.

The guts of this fiſh have a very peculiar ſtructure. In the upper part of them, inſtead of the ordinary circumvolutions of the guts of animals, the cavity is diſtinguiſhed by many tranſverſe ſeparations compoſed of the membranes of the inteſtine turned inwards: Theſe ſeparations ſtand at about half an inch diſtance from one another, and turn helically like a ſnail-ſhell. The conſequence of this is, that the food is detained a long time in its paſſage, though the way it has to go be very ſhort. This creature feeds both on other fiſh, and on ſea-plants; and it is very remarkable, that the fiſh it has devoured are ſometimes found in its ſtomach without the head, ſcales, ſkin, and bowels, the muſcular fleſh remaining entire, while all theſe harder and tougher parts are diſſolved. Ouvrage adoptez de l'Acad. Par. vol. 1.

VULTURIUS, among the Romans, a throw of the *tali*, otherwiſe called *canis*. *Pitiſc.* in voc. See the articles Canis and Talarius *Ludus*.

VULTURIUS *Lapis*, a name given by many to the ftone called *quandros*. See the article QUANDROS.

VULTURNALIA. See the article VOLTURNALIA.

VUNENA, a name given by the people of Guinea to a kind of catch-fly, or lychnis, common in that part of the world, and much ufed by them in a decoction to cure fwellings of the legs. Petiver has called it *lychnis Guineenfis fructu caryophylloide foliis roris marini, hirfutis, anguftioribus*. Phil. Tranf. N°. 232.

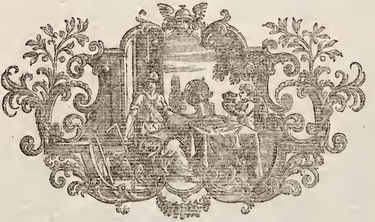
UVULA, (*Cycl.*) in anatomy, is alfo called *columella, gargareon*, γαργαρ, *gurgulio, uva, uvigena, uvigera, epiglottis*, and *cion*. *Blancard* in voc. *Cion*.

The cutting out of the *Uvula*, when fwelled and hanging down, is commonly practifed in Scotland, and no other remedy applied than a piece of bread and cheefe. The furgeon, who is fome neighbouring peafant, ufes alfo no other inftrument than his knife; and yet all fucceeds very well.

UVULÆ *Prolapfus*. See the article PROLAPSUS.

UVULARIA, in the materia medica, the name given by authors to the plant called *hypogloffum*, or double-tongue. *Dale*, Pharmac. p. 169.

UXOR, in the language of the chemifts, the mercury of metals. This is the wife they fay, and fulphur is the hufband. See the article MARITUS.



W.

WADD (*Cycl.*)—WADD-*Hook*, or WORM, a small iron turned serpent-wise like a screw, and put upon the end of a long staff, to draw out the *Wad* of a gun, when it is to be unloaded.

WAGE, in the law of England, is used for the giving security for the performance of any thing. Terms de Ley. in voc.

Thus we say, to *wage law*, to *wage deliverance*. See the article GAGE.

None *wages* law against the king. *Brook*, Abr. Tit. chose en Action. 6.

WAGGEL, in zoology, a name given by the people of Cornwall to a species of the *larus*, or sea-gull, known among authors by the name of *martinozzo*. See the article MARTINOZZO.

WAGGON (*Cycl.*)—WAGGON-*Master-General*, in the military art, is he who has the ordering and marching of the baggage of the army. On a day of march he meets the baggage at the place appointed in the orders, and marshals it according to the rank of the brigade or regiment each *Waggon* belongs to, which is sometimes in one column, sometimes in two; sometimes after the artillery; and sometimes the baggage of each column follows their respective column.

WAIN, a vehicle or carriage drawn by oxen. See the article CART.

WAKE-*Robin*, *Arum*, a medicinal plant. See the article ARUM.

WALDRAPP, in zoology, a name given by some to the wood-raven, or *corvus sylvaticus* of Gesner, a bird of the size of a hen, of a glossy black, and adorned with a crest on its head. See the article CORVUS.

WALE, or WAIL, in a ship, those outermost timbers in a ship's side, on which men set their feet when they clamber up a ship's side. They are reckoned from the water, and called her *first*, *second*, or *third Wale*, or *bend*.

WALE-*Knot*, aboard a ship, a round knot or knob made with three strands of a rope, so that it cannot slip, by which the *tacks*, *top-sail-sheets*, and *stoppers*, are made fast, as also some other ropes.

WALE-*reared*, on board a ship, a name the seamen give to a ship, which, after she comes to her bearing, is not narrow in her upper work, nor *housed in*, as their word is, but is built strait up; which way of building, though it does not look well, nor is, as they say, *ship-shapen*, yet it hath this advantage, that a ship is thereby more roomy within board, that is, she is larger within, and also becomes thereby a wholsome ship in the sea, especially if her bearing be well laid out.

WALINGHURU, in botany, a name by which some authors have called the plant, of which the medicinal zerumbeth is the root. *Herm.* Mus. Zeylon, p. 51.

WALK (*Cycl.*)—WALK, in the manege, is the slowest and least raised of all a horse's goings. The Duke of Newcastle says, that this motion is performed with two legs, diametrically opposite in the air, and two upon the ground at the same time, in form of a saint Andrew's cross: but this, in reality, is the motion of a trot; and accordingly all the later writers agree, that this author is mistaken, and that the *Walk* is performed, as any one may observe, by the horse's lifting up its two legs on a side, the one after the other, beginning with the hind-leg first. Thus, if he leads with the legs of the right side, then the right foot he lifts is the far hind-foot, and in the time he is setting it down (which in a step is always short of the tread of his fore-foot on the same side) he lifts his far fore-foot, and sets it down before his near fore-foot. Again, just as he is setting down his far fore-foot, he lifts up his near hind-foot, and sets it down again just short of his near fore-foot, and just as he is setting it down, he lifts his near fore-foot, and sets it down beyond his far fore-foot.

This is the true motion of a horse's legs in a *Walk*; and this is the pace in which many things are best taught. For instance, when the horse is to be taught to turn to the right and left, or from one hand to another, he is first to be taught it on the *Walk*, then on the trot, and finally on the gallop.

Grass WALKS. See the article GRASS.

Gravel WALKS. See the article GRAVEL.

WALKÆPETHIGA, in botany, a name by which some authors have called the tree, on which the gum lacca of the shops is usually found. *Herm.* Mus. Zeyl. p. 34.

WALL (*Cycl.*)—Of all the materials for building *Walls* for ripening fruit, brick is generally the best, as it reflects a great deal of heat, retains its warmth a great while, and affords, by the smallness of the joints, the convenience of fastening up the trees with small nails. If these *Walls* are coped with free-stone, and have stone pillasters at proper distances, to break the force of the winds, and shelter the fruit-trees, they make the most advantageous, as well as the most beautiful of all *Walls*.

It is sometimes an advantageous thing to build these *Walls* upon arches, that the roots of the trees may have room to spread under, and to the other side of them. This is necessary when the soil is a hard gravel; for without this, when the roots of peaches, &c. have reached the gravel, they find not sufficient nourishment, and the trees canker and die. But though Mr. Fairchild had found great advantages from this way of building *Walls*, Mr. Miller disapproves it. Some also have proposed the building slanting *Walls*; but the same author gives many reasons why the perpendicular are preferable, and seems to think that if *Walls* could be easily contrived to slope a little forward, they would be even preferable to these. *Miller*'s Gardener's Dict.

WALL *of Severus*. See the article AGGER.

WALL-*Flower*, in botany. See the article LEUCOIUM.

WALL-*Moss*, *Bryum*, in botany, the name of a genus of mosses, the characters of which are these: They produce membranaceous capsules, covered with a calyptra or hood, and standing on pedicles more or less long. In all this they agree with the hypnums; but they differ from them in that this pedicle has no covering round its base, but in the place of it has a node or tubercle. These pedicles also usually arise from the tops of the branches, or from those of the last years, which were then the tallest, though now nearer the roots. To this it is to be added, that the stalks are usually erect, less branched than in the hypnums, and not creeping. The calyptræ in some species stand strait, in others obliquely on the capsules; and the opercula, when the dusty matter within the head has arrived at its maturity, fall off transversely, sometimes with a smooth, sometimes with a jagged eye.

The family of the *bryums* being very numerous, they are divided into several orders and series. The first order comprehends those which have erect heads, and of these those of the first series have rounded, bellied, and turbinated heads.

Of this series the following are the know species: 1. The hair-leaved globe *Bryum*. This is called by some the *apple-headed moss*; it is a very beautiful species; the stalks are about an inch long, and stand in tufts, and the heads are round and placed on long pedicles; the leaves are of a dark green. It is common on ditch-banks. 2. The slender star-topped marsh *Bryum*, with round heads. This is another very beautiful kind. The leaves composing the starry tops of the branches are more rigid and stiff than the rest. It is common in wet places. 3. The narrow-leaved *Bryum*, with transparent thyme-like leaves, and heads shaped like cruets. This also is a beautiful species. It grows in wet mossy places, but is not very common. 4. the wide-necked cruet *Bryum*, with transparent mother-of-thyme leaves. This is found in boggy places in the west of England. 5. The narrow-leaved slender cruet *Bryum*. This is a beautiful plant, it grows to four inches in height, and is usually found on heaths about cow-dung. 6. The pear-headed *Bryum*, with transparent mother-of-thyme leaves. This is very common in February about hedges, and in shady places. *Dillen.* Hist. Musc. p. 336.

The second series of this order of *Bryums* contains those which have oblong, oval, and rounded heads. Of these the first division comprehends those which have broad leaves. Of these the following are the known species: 1. The small thyme-leaved *Bryum*, with thick-set rusty heads. This is very common on ditch-banks, and by way-sides, and produces a great number of heads. 2. The lesser extinguisher *Bryum*. The calyptra of this species exactly resembles an extinguisher. It grows in thick tufts, and its leaves are pellucid, and somewhat like those of the serpyllum. 3. The larger extinguisher *Bryum*. This is larger than the former, and somewhat branched; it grows also in thick tufts. 4. The awl-headed *Bryum*. The leaves of this are of a pale green, oblong, and hollowed in the middle; the pedicles of the heads are long, and moderately thick. It is common on ditch banks in January and February. 5. The transparent *Bryum*, with leaves leaning all one way. The leaves are obtuse and pellucid;

lucid; the pedicles of the heads about an inch long, and the heads themfelves flender. It grows in fandy places in Virginia. 6. The hoary branched country *Bryum*, with coloured heads. This grows in thick tufts, and is very common in country villages on the trunks of trees, walls, and houfes. 7. The fmooth *Bryum*, refembling the former kind. The leaves of thefe are fmaller than thofe of the other, and fmooth, and the whole plant lefs. It grows in Patagonia. 8. The common dwarf hoary wall *Bryum*. This is a very fmall fpecies, extremely common on old walls, and the tiles of houfes. 9. The common dwarf tranfparent *Bryum*, with green, not hoary leaves. This refembles the former in figure, but its leaves are broader, thinner, and more pellucid. It grows in many places on ditch-banks. *Dillen.* Hift. Mufc. p. 354.

The fecond divifion of this order of the *Bryums*, comprehends thofe with narrower leaves, of which fome are remarkably longer than others: Of thefe the following are the known fpecies: 1. The fickle-leaved bending befom *Bryum*. This is a large and erect fpecies, very common in thick tufts about hedges. 2. The red-ftalked, tranfparent, graffy-leaved *Bryum*. The ftalks are flender; the leaves of a pale green; it grows in many parts of Germany, but has not yet been obferved in England. 3. The tranfparent, hart's-tongue-leaved curled *Bryum*, with crooked heads. This is a very common fpecies. It grows to two or three inches high, and its leaves are long, narrow, and alated. 4. The juniper-leaved curled *Bryum*, with ftraiter heads. The leaves of this are narrower than thofe of the former, and lefs curled; it is very common in Virginia. 5. The larger brittle whitifh *Bryum*, with ftrait leaves, and fhort pedicles. This is a very common fpecies in wet places on heaths. It grows in very thick tufts, and imbibes and retains a great quantity of water. 6. The dwarf white larix-leaved *Bryum*. This grows in fmall and fhort tufts, and is a native of North America. *Dillen.* Hift. Mufc. p. 360.

The fecond fubdivifion of the narrow-leaved *Bryums* contains thofe of the fhort-leaved kind; of thefe the following are the known fpecies: 1. The white brittle *Bryum*, with crooked leaves. This is much like the common white heath *Bryum*; but the leaves are bent, and the pedicles of the capfules grow out of the fame parts of the ftalks, whereas in that they grow from the tops. 2. The tranfparent bog *Bryum*, with crooked fhort leaves and heads. This is common in marfhy places; it grows to two or three inches high, and ufually in very thick tufts. 3. The fhort-headed *Bryum*, with drooping leaves. This is of a yellowifh-green, and grows on wet places in the Welch mountains. 4. The fharp-headed *Bryum*, with leaves leaning one way. This grows to two inches high, and is not uncommon in the northern parts of England. The hypnum-like water *Bryum*, with pointed black calyptræ. 5. This is a very fingular fpecies; it grows in water, and lies upon ftones; but does not properly creep or root itfelf on them. It is found in rivulets in mountainous places. *Dillen.* Hift. Mufc. p. 366.

The third divifion of the firft order of *Bryums* comprehends thofe with extremely narrow, or capillaceous leaves. Of thefe fome refemble the hypnums, and many of thefe have their leaves terminated by long hairs. Of thefe the following are the known fpecies: 1. The common hoary hypnum-like *Bryum*. This is of a yellowifh green, and when dry becomes whitifh. It is confiderably branched, and is found on Hampftead-Heath, and in the like places. 2. The green cluftery Alpine *Bryum*. This is of a greenifh yellow colour, but wants the hairs which terminate the leaves of the former kind. It is common in the mountainous parts of Wales and Yorkfhire. 3. The fmall-headed hypnum-like Alpine *Bryum*. This is a fmall mofs, but much branched; the leaves are very narrow. It grows in the mountains of Wales and Yorkfhire, and is fometimes found quite black, both in leaves and ftalks. 4. The hypnum-like Alpine *Bryum*, with obtufe calyptræ. The branches of this are hairy, the leaves very numerous and very fmall, and of an obfcure brownifh green. It grows on the hills in Wales and Yorkfhire. 5. The heath-like Alpine *Bryum*, with bearded heads. The ftalks of this are lefs branched than in the former, and the leaves fhorter; it grows in mountainous places in Yorkfhire. 6. The many-headed, hoary, hypnum-like mountain *Bryum*. The ftalks of this are rigid, and are four or five inches long, fometimes fingle, fometimes branched. The leaves are narrow, and end in fine fmall hairs. It is found in the mountainous parts of Yorkfhire. *Dillen.* Hift. Mufc. p. 370.

The fecond fubdivifion of thefe *Bryums* contains fuch as are hairy, and have capillaceous leaves; but differ from the hypnums in their proper figure, and general appearance. Of thefe the following are the known fpecies: 1. The foft-hair pencil *Bryum*, with crooked fhanks. This is a very minute mofs, but very beautiful; its leaves terminate in fine hairs, and its heads are fmall. It is not unfrequent in the woods of Germany, but is not common in England. 2. The bright green, pointed fphagnum-like *Bryum*. This grows an inch or two high, and its branches are ufually divided into two or three at the ends. It grows on the mountains of Yorkfhire. 3. The whorled-hair *Bryum*. This grows in very thick tufts. The ftalks are flender, and about an inch long. The leaves are capillaceous, and the heads fmall and roundifh. It is found on the trunks of trees, and on the ground in the northern parts of England not unfrequently. 4. The conferva-like bog *Bryum*. This is very fmall, and compofed of extremely flender branches, which entangle with one another, and are furnifhed with fmall leaves placed alternately, and not fet very clofe; it grows in wet places. 5. The bending hair-pencil *Bryum*. This is a very elegant little mofs. It grows in thick tufts on ditch-banks, and is not above half an inch in height. The leaves are long and capillaceous; the heads very fmall and reddifh. 6. The cluftery crooked-leaved hair *Bryum*. This is a fmall mofs, the ftalks fometimes fimple, fometimes branched; the capfules are very flender, and their pedicles reddifh. This grows on the mountains of Wales. 7. The black-headed bog *Bryum*, with fhort leaves. The ftalks of this are flender, and feldom branched; the heads are fmall and of a blackifh brown, and the pedicles fhort. It is common in Yorkfhire. *Dillen.* Hift. Mufc. p. 376.

The third fubdivifion comprehends fuch of thefe *Bryums* as have curled leaves, or leaves that become varioufly undulated as they dry. Of thefe the following are the known fpecies: 1. The long-fhanked frizzled *Bryum*. The ftalks of this grow to near two inches high; the leaves ftand very thick, and always curl up in the drying. It is found in mountainous places. 2. The fhort-fhanked, many-headed frizzled *Bryum*. This has fhorter ftalks than the former, and the leaves ftand in clufters on the tops; it is found on the mountains of Wales and Yorkfhire. 3. The fine ftar-topped *Bryum*, which curls up its leaves in drying. This grows in thick tufts, and its leaves are of a beautiful green; it is common on heaths, and under hedges. 4. The fhort pale green hair *Bryum*, with oval heads. This is a very fmall mofs, but it grows in thick tufts; the leaves, while frefh and vigorous, are expanded, and form ftellar tops to the branches; but, in drying, they curl up and wither. It is very common on ditch-banks. 5. The neat pale green *Bryum*, with ftarry tops, and flender heads. This is a very fmall fpecies; but its ftalks are divided into fome branches. Its leaves form ftarry tops to the branches, while frefh; but they curl up and lofe their figure in drying. 7. The fmall red ftar-topped bog *Bryum*. The ftalks of this are moderately long and branched; the leaves alfo are long. It is found in the mountains of Wales. 8. The fmooth and flender pale-fhanked *Bryum*, with thick-fet leaves. This is frequent at the bottoms of old walls. *Dillen.* Hift. Mufc. p. 379.

The fourth fubdivifion of thefe *Bryums* comprehends thofe which have roftrated calyptræ and pointed capfules, afterwards becoming of the fhape of bottles, from the rim of which there grow up feveral oblong bodies, in form of a beard. Of this kind are the following fpecies: 1. The thick-topped bearded birds-claw *Bryum*. The ftalks of this are fhort, fometimes branched, fometimes not; the leaves fmall, ftrait, carinated, and of a lively green. It is common on old walls. 2. The fmall ftar-topped *Bryum*, with clawed and bearded heads. The ftalks of this are fhort; the leaves ftellate at the tops; the pedicles of the heads grow not from the fummits, but from the laft year's top of the ftalk. It grows on the ground, and is found in Germany, and in fome parts of England. 3. The flender-bearded *Bryum*, with narrow and thin-fet leaves. The ftalks of this are very flender, and fend up their pedicles from the fummit. It is common on the earth in dry places, and fometimes on old *Walls*. *Dillen.* Hift. Mufc. p. 381.

The fifth fubdivifion of thefe *Bryums* comprehends thofe which have a fhorter operculum, and whofe capfules appear ftriated when fully ripe. Of this kind are the following fpecies: 1. The fmall forked *Bryum* with twin heads. The ftalks of this are fhort, and ufually fend up two pedicles from each fummit, each carrying its capfule. The leaves are fmall, and of a dark green. 2. The ftarry-topped red-fhanked *Bryum*. This grows in clufters or tufts; the ftalks are divided fometimes into two, fometimes into three branches. It is very common by way-fides, and is eafily known by the rednefs of the pedicles. 3. The fine-leaved bog-*Bryum*, with long and fhining-red pedicles. This grows in the manner of the former; but the leaves are longer, and more pointed, and the pedicles are long, and grow feveral together from one ftalk. It is common in Wales. *Dillen.* Hift. Mufc. p. 387.

The fixth fubdivifion of thefe *Bryums* takes in thofe which have either no ftalks, or at the utmoft only very fhort ones. Of this kind are the following fpecies: 1. The leaft dwarf hair *Bryum*, with fhort heads and pedicles. This has extremely narrow leaves, of a deep green; it grows in marfhy places. 2. The fmall black, hair *Bryum*, with longifh heads and pedicles. The heads of this are large, and their pedicles are confiderably long. 3. The dwarf fine-leaved heath-like *Bryum*. The leaves of this fpecies are very rigid, and greatly refemble thofe of the fine-leaved heath. It grows on rocks and ftones in the weftern parts of England. 4. The dwarf tufted *Bryum*, with fine foft leaves, and conic heads. The leaves of this are very narrow and carinated, and of a deep green. It grows by the fides of rivers in Virginia, Penfylvania, and other parts of America. 5. The dwarf long-fhanked *Bryum*, with hairy leaves, all leaning one way. This

This also is common in Virginia. 6. The golden long-shanked hair *Bryum*, with upright crooked heads. The stalks of this are very short, and sometimes a little branched. It is a summer-moss, and is frequent in Germany.

The second order of the *Bryums* comprehends those which have capsules, hanging downward from the bending of the pedicles. The calyptræ in these species quickly fall off; and the opercula are usually obtuse.

The first series of these comprehends those which have extremely narrow leaves. Of this series the following are the known species. 1. The short-shanked hair *Bryum*, with red stooping heads. The capsules of this seem in a middle state between the erect and pendent ones. It grows in moist grassy places, but is not very common. 2. The golden-hair *Bryum*, with pear-like bowing heads. The stalks of this are low, and rather may be called creeping fibres; the leaves of a pleasant green, and very narrow; the pedicles are an inch high, and the heads yellow when ripe. It is found in many parts of England in moist places. 3. The lovely green hair *Bryum*, with pendulous heads. The capsules of this are oblong and drooping, the leaves are extremely narrow. It grows in wet places on Woolwich-Heath. *Dillen.* Hist. Musc. p. 386.

The second series of these *Bryums* contains those which have leaves a little broader, and though narrow, not capillaceous. The first division of these contains those which have equal and cylindric branches. Of these the following are the known species: 1. The catkin-stemmed silver *Bryum*. This is a very small moss; but it grows in extremely large tufts, and is very common on the tiles of houses; its silvery look distinguishes it from all the others at first sight. 2. The round-stemmed green *Bryum*, with pendulous heads. The capsules of this are of an oval figure; it grows on walls. 3. The hypnum-like *Bryum*, with elegant blackish-red heads. This is found on the Welch mountains. *Dillen.* Hist. Musc. p. 393.

The second division of these comprehends those which have unequal and irregularly-shaped branches. Of these the following are the known species: 1. The hoary round-tufted tile *Bryum*, with pendulous heads. This is an extremely small moss, and grows usually on little round tufts; the heads are not seen till the plant is closely examined; they stand on very short stalks. This is one of the most frequent of all the mosses on old *Walls* and the tiles of houses. 2. The tufted red and yellow-shanked *Bryum*. The leaves of this are broader, membranaceous, and of a pleasant green. It is common on old walls. 3. The transparent and larger tufted *Bryum*, with long pendulous heads. This is common on heaths; it is of a pleasant green, and grows to two inches high. 4. The transparent-leaved *Bryum*, with long pendulous heads. This is common in moist shady places. 5. The lancet-leaved *Bryum*, with round flesh-coloured pendulous heads. This is found in the summer months on Black-Heath, and in many other places about London. 6. The tender, lancet, and grass-leaved pendulous *Bryum*. The stalks of this are red; they do not exceed half an inch in height, and are not branched; the pedicles are of a pale red, and grow from the summits of the stalks. It grows in tufts in Wales. 7. The swans-neck *Bryum*. This is a very elegant species, it grows in woods, in somewhat moist places, and is an inch or two, sometimes more, in height. The leaves are large, and of a beautiful green, and the pedicle bends with the capsule, so as to represent the head and neck of a swan. It is common in our woods. 8. The pendulous and swoln-headed bog *Bryum*. This grows to three or four inches high; the leaves are like those of serpyllum, and are pellucid, and of a lively green. It grows in boggy places on heaths, &c. 9. The long-shanked bog *Bryum*, with long pendulous heads. This is not unfrequent with us in damp places, in woods, and under shady hedges. 10. The red bog *Bryum*, with plated leaves, and pear-shaped pendulous heads. This is found in many parts of England on mountainous boggy grounds. *Dillen.* Hist. Musc. p. 397.

The third series of these *Bryums* comprehends such as have broad leaves. Of this kind the following are the known species: 1. The golden bulbed *Bryum*, with pear-fashioned bowing heads. This is called by some *little goldilocks*, or *golden maidenhair*. It is a very common moss, and grows on the ground. 2. The many-headed pendulous shrub *Bryum*, with pellucid leaves, resembling those of the hart's-tongue. This is a very common moss; it creeps at the root, and spreads very fast; it grows in woods, and under hedges. 3. The larger starry rose *Bryum*, with pendulous oval heads. The stalks of this are naked near the ground; but on their upper part they have many small leaves. It grows in moist and shady places. 4. The lesser starry rose *Bryum*, with long pedicles, and long heads. The leaves of this are very short. It is not uncommon under shady hedges. 5. The pendulous oval headed *Bryum*, with various transparent leaves. The stalks of this are about half an inch high, and the leaves obtuse, and short toward the bottom, and longer and narrower at the top. It is very common in wet places on heaths and woods. 6. The long transparent serpyllum-leaved *Bryum*, with sharp stooping heads. This grows in marshy places. 7. The round transparent mother-of-thyme-leaved *Bryum*, with pendulous oval heads. This has but small leaves, and grows always in boggy places; the heads are of a pale green while young, and of a pale yellow when ripe. *Dillen.* Hist. Musc. p. 415.

WALLA, the name of an officer in the eastern nations. The Arabs have the care of the country round about the city of Cairo in Egypt, and a *Walla* is obliged to patrole continually about there, especially in the night.

His business is to take up all persons who are committing any disorders, or who cannot give an account of themselves, or are found abroad at irregular hours; and he often has their heads cut off upon the spot. As this officer is naturally the terror of rogues, so for presents made to him he often becomes their protector. Without this they are sure, one time or other, to fall a sacrifice to his resentment; and to him the great people send for any villains who have rendered themselves obnoxious to them, and are sure to have them delivered up. *Pocock*'s Egypt. p. 165.

WALLING *of Brick.* See the article BRICK.

WALNUT, in botany. See the article NUX.

The effluvia of *Walnut-trees* are said to be hurtful to the head. Mr. Boyle assures us they caused the head-ach in himself. Works abr. vol. 1. p. 436.

WALRUS, in zoology, the name by which some authors call the morse, or sea-horse, called also by others, *rosmarus*, a creature very different from the *hippopotamus*, or river-horse. See the article MORSE.

WALT, at sea, is applied to a ship, when she hath not her due ballast, *i. e.* not enough to enable her to bear her sails.

WALTHERIA, in botany, the name of a genus of plants, the characters of which are these: The perianthium consists of one leaf, and is of the shape of a cup, lightly divided into five segments, and remains after the flower is fallen. The flower consists of five petals, which are cordated at the top, and stand expanded. The stamina are five filaments, growing together into a cylinder. The antheræ are simple, and stand free. The germen of the pistil is oval. The style is simple, somewhat longer than the stamina; and the stigma is bifid. The fruit is a capsule of an oval figure at the top, composed of two valves, but containing only one cell. The seed is single, obtuse, and broad. *Linnæi* Gen. Plant. p. 327.

WAMPUM, a sort of shells, several of which being strung upon threads, are used as money among the Indians.

It is made of a shell, formed into small cylinders, of about one quarter of an inch long, and a fifth of an inch over, and being bored as beads, is strung in great numbers upon long strings. In this state it passes among the Indians in their usual commerce, as silver and gold among us; but being loose, it is not so current.

It is both white and black; and the meanest is in single strings, of which the white goes at five shillings a fathom, and the black at ten; or by number, the white at six a penny, the black at three. The next in value to the single strings, is that which is wove into bracelets of about three quarters of a yard long, black and white, in stripes, and six pieces in a row, the warp consisting of leather thongs, and the woof of thread: these the gentlewomen among them wear, wound twice or oftener about their wrists.

The most valuable of all is that woven into girdles. These are composed of many rows, and the black and white pieces woven into squares or other figures. These girdles are sometimes worn as their richest ornaments; but they are oftener used in their great payments, and make their noblest presents, and are laid up as their treasure. *Grew*'s Museum, p. 370.

WANDSU, in zoology, the name of a species of monkey found in the island of Ceylon. It is all over of a fine deep black; but has a long white beard hanging from its chin.

WANHOM, in the materia medica, a name by which Kæmpfer has called the plant, of which the great galangal of the shops is the root. *Kæmpf.* Amæn. Exot. p. 901.

WANT, in zoology, a name given by many to the mole. See the article TALPA.

WANTI. See the article GLOVE.

WAPP, in a ship, that rope wherewith the shrowds are set taught with wale-knots, one end is made fast to the shrowds, and to the other are brought the lanniards.

WAPPER, in zoology, a name given by some to the smaller species of the river-gudgeon. *Ray*'s Ichthyogr. p. 264. See the article GOBIO *Fluviatilis.*

WAR (*Cycl.*)—WAR-*Horse.* The proper rules for the choosing a horse for service in *War*, are these: He should be tall in stature, with a comely head, and out-swelling forehead. His eye should be bright and sparkling, and the white part of it covered by the eye-brow. The ears should be small, thin, short, and pricking; or, if long, they should be moveable with ease, and well carried. The neck should be deep, and the breast large and swelling. The ribs bending, the chine broad and strait, and the buttocks round and full. The tail should be high and broad, neither too thick, nor too thin; the thigh swelling; the leg broad and flat, and the pastern short. When such a horse is chosen, he must be kept high during the time of his teaching, that he may be full of vigour. His food must be sweet hay, and good clean oats, or two parts of oats, and one part of beans or peas, well dried and hardened. The quantity should be half a peck in the morning,

ing, and the ſame quantity at noon, and in the evening. Upon his reſting-days he is to be dreſſed between five and ſix in the morning, and watered at ſeven or eight. In the evening he is to be dreſſed at four, and watered about five, and he muſt always have provender given him after watering; he muſt be littered about eight, and then muſt have food given him for all night.

The night before he is ridden, all his hay is to be taken away about nine o'clock, and he muſt have a handful or two of oats about four in the morning, when he has eaten theſe, he is to be turned upon the ſnaffle, and rubbed very well with dry cloths; then ſaddled, and made fit for his exerciſe. When he has performed this, he is to be brought ſweating into the ſtable, and rubbed down with dry wiſps. When this has been done, the ſaddle is to be taken off, and he is to be rubbed down with dry cloths; the houſing cloth is then to be laid on, and the ſaddle being again laid on, he is to be walked gently about till thoroughly cool. After this, he muſt ſtand without meat two or three hours, then he muſt be fed; and in the afternoon he is to be rubbed and dreſſed as before, and watered in the uſual manner.

WARD's *Pill.* Some have conjectured that this medicine, which had ſo great a run, and to which a diminution of the numbers in the bills of Mortality, one year after it happened to come in vogue, was ſaid in a public advertiſement to be owing; it has been conjectured, I ſay, that this medicine was made of butter of antimony; others think it the glaſs of antimony, and cinnabar of Antimony amaſſed with gum tragacanth. See *Ward's Pill* diſſected, and Med. Eſſ. Edinb. abr. vol. 2. p. 434 and 470.

Mr. Clutton mentions ſome caſes where they did ſervice; but relates the hiſtories of fifty caſes where they did great miſchief.

To diſcover the compoſition of theſe pills, he diſſolved the ſeveral ſorts of them, and then viewing with a microſcope the powder which precipitated, he ſaw three different coloured powders remaining of the blue pill; to wit, a yellow, red, and white powder; the yellow and red agreed exactly with the glaſs of antimony, and the white one appeared to be common arſenic. *Ward's Pill* being incloſed in copper, and expoſed to a ſtrong heat, made the copper white, and as hard as iron, which arſenic always does. He alſo obſerved in this blue pill another powder, which he judged to be zaffre, that is, calcined cobalt, incorporated with flints. He thinks the proportion of the ingredients in this blue pill to be, one third glaſs of antimony, near two thirds of arſenic, and a very ſmall part of cobalt, or zaffre, with ſome powder of blue.

The red pill appeared to be much the ſame compoſition as the blue, only red arſenic was made uſe of inſtead of the white, and that the colouring of blue powder was left out.

The purple pills tinged glaſs blue, which cobalt or zaffre does, and therefore Mr. Clutton thinks them principally compoſed of cobalt, with a little glaſs of antimony, which left a yellowiſh border upon the glaſs. See *True and candid Relation of the good and bad Effects of* Ward's *Pill and Drop*, and Med. Eſſ. Edinb. abr. vol. 2. p. 470, 471.

WARNAS, a name by which ſome of the chemical writers expreſs what others of them call the *acetum philoſophorum*, or vinegar of the philoſophers.

WARNING (*Cycl.*)—WARNING-*Piece*, in the military art, is the gun which is fired every night about ſun-ſet, to give notice to the drums and trumpets of the army to beat and ſound a retreat or tattou, which is likewiſe called, ſetting the watch. See the article RETREAT.

WARNOTH, in our old writers, an antient cuſtom by which if a tenant, holding of the caſtle of Dover, failed in paying his rent at the day, he was to forfeit double; and for the ſecond failure, treble: and the lands ſo held were called *terris cultis*, and *terris de Warnoth*. *Blount.*

WARPS (*Cycl.*)—WARP, in a ſhip, a rope uſed to hale a ſhip into, or out of a harbour.

WARRANT, (*Cycl.*) in the manege. A jocky that ſells a horſe is, by cuſtom, in ſome countries, obliged to *warrant* him, that is, to refund the money that was given for him, and re-deliver the horſe in nine days after the firſt delivery, in caſe he ſold him when under ſuch infirmities as may eſcape the view of the buyer, and as are not obviouſly diſcovered. Theſe infirmities are purſiveneſs, the glanders, and unſoundneſs, hot and cold: But he does not *warrant* him clear of ſuch infirmities as may be diſcerned. Not only jockeys or horſe-merchants, but alſo perſons of what quality or condition ſoever, are obliged to take back the horſe, and repay the money, if he is affected with the ſaid diſorders. But the rule of the law of England is, *caveat emptor*, unleſs the ſeller expreſly *warrants*.

Dividend WARRANTS. See the article DIVIDEND.

WARREN (*Cycl.*)—The word *Warren* is now generally applied to a piece of ground ſet apart for the breeding and preſerving of rabbets.

In the ſetting up a *Warren*, great caution is to be uſed for the fixing upon a proper place, and a right ſituation. It ſhould always be upon a ſmall aſcent, and expoſed to the eaſt or the ſouth. The ſoil that is moſt ſuitable, is that which is ſandy; for when the ſoil is clayey or tough, the rabbets find vaſtly more difficulty in making their burrows, and never do it ſo well; and if the ſoil be boggy or mooriſh, there would be very little advantage from the *Warren*; for wet is very deſtructive of theſe animals.

All due precautions muſt be taken, that the *Warren* be ſo contrived, that the rabbets may habituate themſelves to it with eaſe. Many would have it that *Warrens* ſhould be encloſed with walls; but this is a very expenſive method, and ſeems not neceſſary nor adviſeable; for we find but very few that are ſo, and thoſe do not ſucceed at all the better for it.

Mr. Chomel's opinion is, that it ought to be ſurrounded with a ditch. This indeed is no fence to prevent the rabbets from going out, unleſs there be water in it; but it marks the intended bounds of the *Warren*, and the rabbets generally confine themſelves within its circumference, though not neceſſarily compelled to do ſo. The ſpace proper for a *Warren* has no limits but the owner's pleaſure; but, in general, the larger it is, the more profitable it alſo proves: and the rabbets, when once accuſtomed to the place, will keep within its bounds, though they are neither hemmed in with walls nor ditches, nor any other fence whatever.

Some have preſcribed the making deep ditches, and conſtantly keeping them ſupplied with water in the ſummer as well as winter ſeaſon, that they may ſerve as fences to the rabbets; but as it is not found neceſſary to fence them in at all, it is extremely injudicious to do it, by means of a thing known to be ſo very prejudicial to theſe creatures, as water is. If the perſon who has ſet up a *Warren* has but few rabbets to ſtock it with, the more patience he muſt have as to the profit of it; but the beſt method of getting quickly into the ſcheme of profit in it, is the buying at firſt a large number of doe-rabbets, all big with young. Theſe being unweildy and heavy, will naturally ſtay in the place, and the young ones will be habituated to it as their native place, and will never run from it. Theſe young ones will ſoon breed again, and the *Warren* will begin quickly to be ſtocked with inhabitants, almoſt all natives of the place. They ſhould not be hunted at all the two firſt years, and but very moderately the third. After this they will increaſe ſo faſt, that ſcarce any body can conceive the numbers that may be taken, and the profit that may be annually made without hurting it.

The *Warren* is the next franchiſe in degree to the park, and when ſpoken of in law, the terms uſed are, the liberty and franchiſe of a free *Warren*.

The beaſts and fowls of a *Warren* are underſtood to be four, the rabbet, the hare, the partridge, and the pheaſant, and no other. Theſe were eſteemed the proper game to be taken by the long-winged hawk.

A foreſt, which is in dignity the higheſt and greateſt franchiſe, comprehends in it a chace, a park, and a free *Warren*; for which reaſon the beaſts of the park, and the beaſts and fowls of the free *Warren*, are as much privileged within the foreſt, as the beaſts of the foreſt itſelf are.

WARTS (*Cycl.*)—There are a thouſand ſuperſtitious remedies for *Warts*, but none of them are of the leaſt conſequence. The ſurgeon's aſſiſtance is the only true method of getting rid of them. There are ſeveral ways of deſtroying them in his hands, as by ligature, extirpation, evulſion, the cauſtic, and the actual cautery. The cure by ligature, is by means of a looſe hair, or a piece of fine and ſtrong ſilk, tied very tight about the root of the *Wart*; and by this means the nutricious veſſels being compreſſed, the excreſcence withers and decays.

The method by extirpation, is to take them up with a pair of plyers, and cut them cloſe off with ſciſſars, dreſſing the wound with the common cauſtic, to remove the roots, if there be any, which would give riſe to a new tubercle.

The cure by cauſtics is beſt performed by cutting off the hard upper part of the *Wart* with a razor or ſciſſars, and then ſurrounding its bottom with a circle of wax, to prevent the ſpreading of the remedies, to touch it daily with oil of tartar, ſpirit of ſalt, aqua-fortis, or butter of antimony.

The cure by cautery is performed by chooſing a cautery of a proper ſize, and with that burning down to the root of the *Wart*. This is the moſt painful of all the methods of extirpating theſe excreſcences; but the pain is but for a moment, and the *Warts* extirpated this way never return again.

The cure by evulſion is performed by anointing them with ſoftening ointment, and then ſeizing them artfully between the thumb and the fore-finger, and forcibly wrenching them out. This is a mountebank method, and a bad one; for it is not only very painful, but the *Warts* commonly grow up again.

Cancerous WARTS. It is no uncommon thing to find on the face, lips, and about the eyes, *Warts* which look blue and livid; theſe are always to be let alone entirely; for when irritated, they frequently degenerate into a cancer, and miſerably torment the parts where they are ſituated. *Heiſter's* Surgery, p. 32.

WART, in the manege, is an excreſcence, or ſuperfluity of ſpongy fleſh, that riſes in the hinder paſterns of coach-horſes, almoſt as big as a walnut. It ſuppurates, and voids red ſtinking matter, and does not cure but for a time, for it returns again.

WARTH,

WARTH, in our old writers, seems to be the same with *ward-peny*, being a customary payment for some castle-guard. *Blount*'s Tenur. 60. *Blount*.

WASH, the distillers name for the fermentable liquor, made by dissolving the proper subject for fermentation and distillation in common water.

With respect to the proper workings of this liquor, great regard is to be had to the containing vessel. Its purity, and the provision for its occasional closeness, are the things to be principally considered. Though it is necessary that the vessel be perfectly clean, yet in the cleansing it great care must be taken that no soap, or other unctuous body, be used, for this would check the fermentation in it; and for the same reason all strong alkaline lixiviums are to be avoided. Lime-water, or even the turbid solution of quick lime, however, may be safely used for this purpose; and this is indeed particularly proper to destroy a prevailing acid, which is very apt to be generated about the sides and bottoms of these vessels, if the warm air has access to them, and thus prevents the order of the fermentation. All strong alkaline lixiviums have as bad an effect on the contrary, and a special care must be had that no corrupt or putrified yeast, nor any remains of former fermented matters, hang about the sides of the vessels, for this would infect whatever should be afterwards put into them. Foulnesses of this kind, when of long standing, are of all others the most difficult to be cured, and often are of great damage to the distiller.

The occasional closeness of the vessel may be provided for by having covers very well adapted to it, in the large way of business, and by the use of valves in the smaller, where common light casks will serve the purpose, while the valve occasionally gives the necessary vent to preserve the vessel, and otherwise it remains perfectly close, and impervious to the air but at discretion.

It is a very prejudicial mistake, in the business of fermenting the *Wash*, to suppose that the free concourse or admission of the external air is necessary to the operation. The express contrary is the truth, and a great advantage will be found in practising upon this supposition. A constant influx of the open air, if it does not carry off some part of the already formed spirit; yet it certainly catches up and dissipates the fine subtle oleaginous and saline particles, of which the spirit is formed, and thus considerably lessens the quantity to be procured. This inconvenience is wholly avoided by the way of close fermentation, by which all air, except that which is contained in the vessel, is kept out. The great secret, in this process, is to have a proper space for the reception of this air, at the top of the vessel, over the surface of the liquor; and when such a space is left, as soon as the fermentation is fairly set on foot, the vessel is to be close bunged down, and left to itself, no more fresh air being left in but what is admitted by the valve. No new air is necessary, when the space unoccupied by the liquor is more than one tenth part of the gage, the artificial air generated in the operation being very seldom of force, to endanger the bursting of the cask, or any other mischief.

This method of close fermentation is practicable to good advantage in the small way of business; but it requires such a considerable time, that it will never be liked by the large dealers, who are in a manner forced to admit the free air, and thus sustain a very considerable loss in the spirit, only to get the operation over in a proper time. Excepting for the necessity of expedition of this kind among the large dealers, it is certain that this slow and imperceptible vinous fermentation is greatly preferable, on all accounts, to the other. During the whole course of this operation, the vessel is to be kept from all external cold and external heat that is considerable, it being necessary that it should be kept in an equable uniform and temperate state, so as not to be cognizable to the senses, either as heat or cold. In the winter a stove-room, such as are common in Germany, would be fittest for this purpose, the vessel being placed at a proper distance from the stove; but at other seasons no particular cautions are necessary with us, provided that the place be well sheltered from the violent heat of the sun, and from the bleak northerly winds.

The operation is known to be over in this close way of fermentation, as soon as the hissing noise ceases, and can no longer be heard on applying the ear to the vessel; and when, on opening it, the liquor is found to be clear, and of a vinous pungent taste; when it is arrived at this state, it should be set by for a time in a cooler place than that in which it was fermented; in this manner it will thoroughly purge itself of its lees, and will become perfectly clear, vinous, and pungent; in this state it should be drawn clear off from the lee, and immediately committed to the still; and by this method a perfectly pure vinous spirit will be procured, greatly better than that which can be obtained by the common way, which those who work large quantities fall into for the sake of expedition.

The action of fermentation works such a change in the body of the tincture or solution, called the *Wash*, as to render it separable by the action of fire, into parcels of matter that are specifically different, and of a nature entirely foreign to what the same liquor would have yielded without the fermentation. The still being charged and luted, and brought to work with a soft boiling heat, there first comes over a quantity of intensely pungent aromatic and nidorous liquor, which, if received into a large quantity of cold water, throws off a copious essential acrid or aromatic oil, though the original subject, before the fermentation, were ever so cooling, mild, or contrary to a spicy nature. This essential oil is found to be the principal thing that gives the predominant or peculiar taste to the spirits, according to the several substances from which they are made; and the spirits are, from the flavour they receive from this, distinguished into malt spirit, melasses spirit, cyder spirit, wine spirit, arrac, and the like. The finest, most subtle, and most efficacious part of this essential oil is what comes first, the portions that come after being gradually more and more viscous and nauseous, and the spirit running in a continued thread from the end of the worm, will be found to change its nature oftener than could be imagined, if tasted at different intervals. Beside this essential oil, the spirit of the first running contains only an acid, more or less in quantity, and more or less pungent and volatile, or sensible to the nose, in proportion as the fermentation has been more or less continued; or according to the degree of acidity acquired in the operation. This acid, and the aqueous part that rises with it, may be kept back by a proper rectification; though where the acid is very volatile, some part of it is apt always to rise along with the totally inflammable spirit, so as to give it a flavour like that of a very much diluted spiritus nitri dulcis. *Shaw*'s Essay on Distillery.

The *Wash* of the malt distiller ought to be about the strength of the ten shilling small-beer; and if the spirit be expected fine, it had better be too thin than too thick. It is only made by mixing the water hot with the malt ground into meal. If the water be too hot, the mixture will become gluey; and if too cool, a part of the virtue of the malt will be lost. Under the right application of the water is to be considered the proper manner of agitating the mass, so that all the parts of the aqueous fluid may come fully and freely in contact with the soluble particles of the subject. When once the water is well saturated by standing on the malt a proper time, it must be drawn off, and fresh poured on, till at length the whole virtue, or all the sugary sweetness of the malt is extracted, and nothing but a fixed husky matter remains behind, uncapable of being farther dissolved by the action of hot or boiling water, or of being advantageously washed or rinsed out by the bare affusion of cold. This artificial and external agitation or stirring about of the mass, is necessary not only in the common way of brewing for the malt distillery, but also in that more expeditious way, now in use with some, of reducing the operations of brewing and fermenting to one, and grinding the malt to a fine meal, which is to be kept in the *Wash* during the whole time, and even put into the still with it, and worked together. The stirring may be repeated to great advantage more than once in each operation, as at the affusion of every parcel of fresh water, in the common way, and at any shortly distant times in the short way, in which it is of greater service. *Shaw*'s Essay on Distillery.

The difference of seasons is found to require some alteration in the direction and management of the business of brewing for the malt-distillery. The water must always be used colder in summer than in winter, and the tincture must be cooled suddenly in close sultry weather, to prevent it from becoming eager or sour. The summer season also gives malt an overforward disposition to ferment, and this impairs the quantity of spirit, and is to be checked by the addition of a quantity of unmalted meal, which being much less disposed to ferment than the malted meal, will restrain and moderate its impetuosity, so as to render the operation suitable and effectual to the production of spirit, a great quantity of which would be otherwise dissipated, and thrown off by a too hasty fermentation, and that especially when the warm air is suffered freely to come at the fermenting liquor. Some of our malt-distillers have a custom of using rye-meal for this purpose; but though this answers the end in moderating the fermentation, as well as the other, yet it gives the spirit a nauseous flavour, which is not easy to be got off or altered to advantage by any known method of rectification. Some of the malt-distillers, the better to prepare their malt, sprinkle it before the grinding with a solution of nitre, or common salt, in fair water, and some, instead of these solutions, use lime-water; but this is not so well adapted to the design of the thing, which, beside the preventing the flying away of the finer part of the flowers in the grinding, is to promote the fermentation, and to increase the quantity of spirit, or add to its pungent acid vinosity.

It has also been judged by some to be of service either in general, or especially at some particular seasons, to acidulate the water employed in brewing, with a small proportion of some vegetable or light mineral, and which is supposed to curb and regulate the fermentation of the tincture, improve the acid vinosity of the spirit, and occasion some small increase of its quantity; and with the same view, tartar, as well as common salt and nitre, have been used in the same manner.

The particular intention of the operator may render also various other additions necessary; thus some, to dispose the *Wash* to yield more spirit, or to give the spirit a greater degree of pungency, and a better flavour, add to it the strong and

and pungent aromatics: the cheapest chosen for this purpose, and the most used, are, the cortex winteranus, ginger, and grains of paradise. *Shaw's* Essay on Distilling.

In the common way, these additions, however, do very little, though by a proper artifice in the management they may be made of considerable use. Upon this foundation, stands a very instructive method used abroad, of making geneva *ab origine*, by mixing the bruised juniper berries among the malt, and brewing the whole together; by this means a compound tincture, or *Wash*, is prepared, which, by fermentation and distillation, affords a spirit much more intimately and homogeneously impregnated with the essence of the berry, than that prepared by our distillers, in the common way of adding the berry to the malt spirit, and distilling it from them again. The inconveniencies that attend the brewing directly with malt, are very considerable, the malt being of a very large bulk, in proportion to the saccharine part, which it can alone impart to the water, and in which its virtues, as yielding a spirit, wholly consist. On this account numerous large vessels, much labour, and great expence, are required to conduct and manage such a business in the large way. The remedy in this, as in many other cases, may be much more easily started, than effectually applied; however the foundation for it seems to consist in the practically reducing the perplexed business of the malt distiller, to the simple business of the fine stiller, or, in other words, in the reducing malt to treacle.

It is very certain, that the thing here proposed, may be effected to perfection by the common processes of infusion and evaporation: but the people concerned in this branch of trade are the only proper persons to try it in the large way, and calculate that advantage and expence, and by that means regularly find whether or not it will be worth while to introduce it as a common method of business.

The experiment may be tried in this manner: When a parcel of wort is brewed in the common manner, and is become fine by standing, let it be decanted clear off, and immediately boiled away in a common copper, till it begins to inspissate, and acquires a dusky brown colour: at this time it must be taken out of the copper, and poured into a balneum mariæ, where the remainder of the evaporation may be made without any danger of burning, and the whole may be reduced to the consistence of treacle; in which form it will keep a long time, and be always ready for use, when occasion requires it. The continuing the evaporation to the end, in the copper over a naked fire, would not only be liable to give it an empyreumatic taste, from the burning, which would remain so strongly in the spirit, as to spoil it; but the violence of the heat acting immediately upon it, would dissipate much of its active part, and there would be a much smaller quantity of spirit procured from it; but if the operation be dexterously and carefully performed, as here directed, the extract, or saccharine matter, though of as full a body, will be abundantly paler than treacle, a little more glutinous, very sweet, and pleasant to the taste, and will have a fine agreeable bitterness, as the flavour goes off, though no hops are used in the preparation. In this manner it may be kept, or transported to other countries, and will always be reducible to the state of wort again, only by mixing common water with it; and this wort will ferment as freely and as fully as that made in the common way, and will yield its spirit in the manner of treacle. *Shaw's* Essay on Distilling.

Glauber and Becher were both convinced of the utility of this scheme, and both laboured hard at the bringing it to bear: Glauber seems to have succeeded tolerably in it; but Becher, who had it in his thoughts to extend the practice to the wines as well as the malt liquors, after a whole year spent in the attempt, declares, that he can scarce believe what Glauber says of it, and so candidly owns himself not possessed of the secret of doing it, that he offers a handsome reward to any body that will inform him of it. What these chemists seem not to have hit on, the way or the best way of doing, seems however, from experiments in small quantities, perfectly practicable; and if it may be brought to bear in the large way, plentiful years, convenient situations, and other helps may be pitched upon, for setting up a new trade of treacle, making at least enough for the distillers use, if it shall not be found practicable to convert this new sort of treacle into potable liquors, or into sugars.

It is possible, that on this plan something may be set on foot at home of the nature of the sugar-worts in our American plantations, which may turn to as good account, and yet be managed with much less labour and expence than we find it possible to do that. When malting in particular cases could not be practised, substitutes of various kinds might be invented to supply its place on this plan: thus, such grain or pulse as cannot be made into malt in the common way, may be boiled in water, instead of being brewed, and an extract made of their clear decoctions, evaporated into a treacle in the same way as the other. The Indians in this manner dissolve their rice into a thin pap, or jelly, by boiling it in water; and afterwards they ferment this into a potable liquor, or a sort of wine, which they preserve under-ground for many years successively. And it may be tried whether this method of malting the Indian corn or maize, or that by putting it in the ground till it sprouts, will be the most serviceable in the article of distillery. Most of the English grains may be easily malted in the common way, and their extract thus made into a sort of treacle, with little trouble, and to very great advantage. It remains to try whether the buck-wheat may be malted in the common way, and put to this use? and whether, by some variation introduced in the way of malting, the nauseous flavour of our rye may not be taken off? All the other vegetable substances intended for brewing, should as much as possible have their fermentable parts reduced to the state of a treacle, sugar, or inspissated juice, not only for the sake of preserving them perfect, but for the greater ease and convenience of working them. Thus the juices of the birch, the sycamore, and many other trees, which bleed freely on being tapped in spring, are readily boiled up to this sort of consistence; and in the same manner, wherever it is worth while, the juices of canes, fruits, and sweet roots may be thickened and preserved.

When once the fermentable parts of vegetables are thus concentrated, and brought together into a small compass, the business of brewing, whether, for the distillers use, or for the making potable liquors, will be very easy and short, the whole being no more than mixing or dissolving the inspissated juice in a sufficient quantity of warm water; and this solution, either alone, or with some trifling additions, will be perfectly fitted for fermentation. *Shaw's* Essay on Distillery.

Wash being of a mucilaginous, or somewhat glutinous nature, requires a particular management to prevent its scorching, and make it work kindly in the still: If it should happen to be burnt in the operation, the spirit will have a most disagreeable flavour, and such as can never be got off again, without very great labour, and a particular treatment, not known to every body. To prevent this ill effect, there must be three things observed; the liquor, or *Wash*, must be made dilute, the fire must be well regulated, and the whole kept in a constant agitation. The manner of making the *Wash* dilute, has been long known among the more judicious distillers in this branch, and they have always found their spirit the purer for it. The fire is easily kept regular, by a constant attendance, and avoiding hasty stirring it, or throwing on new fuel; and the stirring the liquor in the still is to be effected by means of a paddle, or bar kept in the liquor, till it just begins to boil, which is the time for luting on the head; and after which there is no great danger, but from the improper management of the fire: this is the common way, but it is hard to hit the exact time, when to lute down the head; and the doing it either too soon, or too late, is attended with great inconvenience, so that many have found out the other methods, of either putting some moveable solid bodies into the still with the *Wash*, or placing some proper matter at the bottom and sides of the still, which are the places where the fire acts strongest.

The use of the paddle would be better than either of these ways, could it be continued while the still is working; and this it may be by the following method: Let a short tube of iron or copper be soldered in the center of the still-head, and let a cross-bar be placed below in the same head, with a hole in the middle, corresponding to that at the top; through both these let an iron pipe be carried deep down into the still, and let an iron rod be passed through this with wooden sweeps at its end; this rod may be continually worked by a winch at the still-head, and the sweeps will continually keep the bottom and sides scraped clean, the interstices of the tubes being all the time well crammed with tow, to prevent any evaporation of the spirit at them. *Shaw's* Essay on Chemistry.

The same effect, may, in a great measure, be produced a less laborious way, that is, by placing a parcel of cylindrical sticks lengthwise, so as to cover the whole bottom of the still, or else by throwing in a parcel of loose faggot sticks at a venture; for thus the action of the fire below moving the liquor, at the same time gives motion to the sticks, and makes them act continually like a parcel of stirrers upon the bottom and sides of the still, which might, if necessary, be furnished with buttons, or loops, to prevent them from starting. Some also use a parcel of fine hay laid upon the loose sticks, and secured down by two cross poles, laid from side to side, and in the same manner fastened down with loops. Care is to be taken in this case not to press the hay against the sides of the still; for that would scorch almost as soon as the *Wash* itself; but the sticks never will: these are simple but effectual contrivances, and, in point of elegance, they may be improved at pleasure.

There is another inconvenience attending the distilling of malt spirit, which is, when all the bottoms, or gross mealy fæculence is put into the still along with the liquor, the thinner part of the *Wash* going off in form of spirit, the mealy mass grows by degrees more and more stiff, so as to scorch toward the latter part of the operation. The method to remedy this, is to have a pipe with a stop-cock, leading from the upper part of the worm-tub into the still; so that, upon a half, or quarter turn, it may continually supply a little stream of hot water, in the same proportion as the spirit runs off, by which means the fear of scorching is taken away, and the operation at the same time not at all retarded. In Holland, the malt distillers work all their *Wash* thick, with the whole body of the meal among it; yet they are so careful in the keeping their stills clean, and so regular and nice in the management of their fires, that, tho' they use no artifice at all on this head, only to charge the still while

while it is hot and moift, they very rarely have the misfortune to fcorch, except now and then in the depth of winter. When fuch an accident has once happened in a ftill, they are extremely folicitous and careful to fcrape, fcrub, and fcour off the remains of the burnt matter, otherwife they find the fame accident very liable to happen again in the fame place. But beyond all the other methods in ufe on this occafion, would be the working the ftills not by a dry heat, but in a balneum mariæ, which might poffibly be fo contrived by the bafon being large, and capable of working a great many ftills at once, as to be extremely worth the proprietor's while in all refpects. *Shaw*'s Effay on Diftillery. See the article MALT-*Diftillery.*

WASH is alfo ufed for the fhallow part of a river, or arm of the fea, as the *Wafhes* in Lincolnfhire. *Blount.*

WASHING (*Cycl.*) WASHING *of Ores*, the purifying an ore of any metal by means of water, from earths and ftones, which would otherwife render it difficult of fufion.

The method of doing it is this: Break the ore to a coarfe powder in an iron mortar, weigh twenty or thirty docimaftical centners of it, put them into the *Wafhing*-trough, and pour fome water upon them, that the ore may be thoroughly moift; then have a veffel full of water, the diameter of which muft be a little larger than the length of the trough; take the trough with the left-hand by the top of the hinder part, and dipping it horizontally into the water, move it gently with the right-hand from the fore part of the trough, which is always to be made the fhallower part of it, toward the hinder part, which is deeper, then take out the trough, and incline it a little on the fore-part that the water may run out, and the heavier metallic part remain at the bottom; repeat this feveral times till the remains at the bottom of the trough are quite pure. If the ftone in which ore is lodged be too hard for powdering in its natural ftate, as the flinty and debafed cryftalline ones commonly are; the whole muft be calcined, and quenched in cold water feveral times over, and afterwards powdered and wafhed in this manner: when it is thus wafhed, affay a centner of it, and from the bead of metal this yields, it will be eafy to eftimate the value of the ore. *Cramer*'s Art of Affaying, p. 244.

WASP. The *Wafp* has four wings and fix feet; his body is yellow, with black triangular fpots: the common *Wafp* breeds in the ground. There is another kind much more fierce, but very rare: thefe breed in woods and mountains; they are larger, and have broader bodies, and much more black about them; their fting is fo large, that it feems difproportioned to the fize of their bodies.

To thefe are to be added the *Ichneumon-wafps*, which are fmaller than the others, and have very flender bodies, but of the fame colours with the common kind: thefe ufually live in the holes of mud-walls, and make a fort of porch of mud before the doors of their habitations.

There is alfo another *Wafp* common about Vienna; this is three times as large as the common kind, and feems of two different fpecies, the one having rough antennæ, and the other fmooth: they are both variegated with black and a bright yellow. *Mouffet*'s Hift. Infect. p. 6.

The *Wafps* conftruct regular combs, and rear their young in the cells of thefe combs in the manner of bees: wherever there is a young worm in a cell, the old *Wafps* frequently thruft their heads into it, and caft up the food for the young one out of their mouths: their cells are hexagonal; and when they have a mind to enlarge their habitation, and make more or bigger combs in them, they are feen very bufily coming out of the mouth of the hole, every one loaded with a parcel of earth, till they have carried out as much as is neceffary for the intended enlargement.

They fupport their combs one over another by crofs pieces of about an inch long, fo that there is ample room for the *Wafps* to pafs in their feveral bufineffes. Thofe cells which ftand in the center of a comb, are always perpendicular; the others all ftand more or lefs obliquely; and in the center, the comb is fomewhat hollowed and depreffed on the face, and convex on the back; and in this part is inferted the principal crofs piece that ferves for a fupport. *Ray*'s Hift. of Infects, p. 250.

The eggs of the *Wafp* are of an oblong form, and refemble thofe of the common fly, but they are larger; they are always faftened to the angles of a cell, never to the fides of it. They are ufually placed fingle; it is very rare to find two in one cell; and if they are laid fo, it feems that one only fucceeds; for there is never found more than one worm in a cell. The egg is always fixed to that angle of the cell which is neareft the center of the comb, and always near the bottom, not in the middle of the cell; and when there are two eggs in one cell, they are never fixed to the fame angle, but ftand at the fame height from the bottom, in the two neareft angles to the center of the comb. The heads of the nymphs are at firft round and pellucid; but foon afterwards the fkull and the forcipes become reddifh. The heads of all the nymphs are turned toward the center of the comb, and their tails go obliquely downward towards the bafe of the cell. They are continually feen opening their mouths, and moving their forcipes, feeming ever hungry, and impatiently waiting for food from their parents. The cells are left open, till the nymph is at its full growth; then the *Wafps* cover it over with a thin lid, under which the worm undergoes its transformation; and as foon as it is arrived at the *Wafp* ftate, it eats its way through this thin cover, and comes to work with the reft.

Mr. Ray mentions a peculiar fpecies of *Wafp*, which builds a much fmaller neft. This is ufually fixed to a beam of fome old building, and has only one aperture, which is about half an inch wide, and ferves for the *Wafps* to go in and out at. This aperture is always exactly oppofite to that part of the hive, where it adheres to the beam. The hive or neft is covered with a thin membranaceous fubftance refembling paper, of a brown colour, with ftreaks of white, difpofed in regular circles. The whole neft is about three inches in diameter, and is ufually compofed of about nine crufts; when thefe are cut away, there appears a round comb in the center, and a fmaller above it, fixed up by a pedicle arifing from the center of each. In every one of thefe cells, which are hexagonal as thofe of the common *Wafp*, is reared one worm, which, in fine, becomes a *Wafp*.

The fpecies of *Wafp* which builds in this manner, differs from the common *Wafp*, in that it is fomewhat larger; it is fmoother alfo, and has rings of a deeper yellow on the back: the black fpots are not fo regular in this, as in the common *Wafp*; and the forehead in this is of a perfect yellow, without any fpots. Thefe marks, with the difference of hanging a fmall neft againft a beam, and building a large one in the ground, are fufficient to diftinguifh this as an abfolutely different fpecies. Befide thefe two, Mr. Ray mentions four other fpecies of *Wafps*: 1. The long and narrow-winged *Wafp*, with long antennæ, and a broad line of black in the middle of the belly. 2. The long and flender black *Wafp*, with three yellowifh-white ftreaks on the belly. 3. The broad and fhort-bodied *Wafp*, with rings of yellow and red. This much refembles the common *Wafp* in fhape. 4. The fharp-tailed *Wafp*, with a black body, variegated with yellow rings. This fpecies is found about old walls, and is furnifhed with but a very weak fting. All the others are found wild in our fields. *Ray*'s Hift. Infect. p. 251.

We have an account in the Philofophical Tranfactions, N°. 476, of fome *Wafp*-nefts made of clay in Penfilvania. Thefe are of two kinds, one plain, fabricated by a fmall black *Wafp*, the figure of which is delineated in tab. 3, of that number. The other is a wreathed tubulated clay neft; and thefe are built by a purplifh black *Wafp*, of the figure there reprefented. When thefe *Wafps* have laid their eggs, it is faid they go and catch fpiders, and cram the cells full of them; and what is remarkable, they do not kill the fpiders, but only difable them, as if they intended to prevent their crawling away, and yet keep them alive.

Mr. Reaumur, in his hiftory of infects, vol. 6. mentions clay nefts from St. Domingo, fomewhat different from thefe.

Ichneumon-WASP. See the article ICHNEUMON.

WASP-*Fly*, in natural hiftory, a fpecies of fly having very much the external figure of a *Wafp*, but harmlefs, without a fting, and with only two wings.

It is black and yellow on the body, and marked exactly as the *Wafp*, and is produced from a fpecies of the rat-tailed flyworms. See the article DRONE-*Fly*.

But befide thefe there is another fmall fly produced of the puceron-eaters, which has extremely the appearance of a fmall *Wafp*; but it is perfectly harmlefs, and has only two wings. *Reaumur*, Hift. Inf. vol. 4. p. 486.

WASP-*Tipula*, in natural hiftory, the name of an infect defcribed by Mr. Reaumur, and being properly a tipula, or long-legs, though greatly refembling a *Wafp*.

This is produced of a worm found in the earth, lodged in the cavities of old trees; the worm has no legs, but has a regularly figured fcaly head. The fly produced from it has the long legs and the mouth of the tipula, with the remarkable double beard which covers it, and which makes the great character of this clafs of infects; but then the body is fhort and thick, whereas the bodies of the common kinds are very bony and thin. This, as alfo the breaft, is variegated with ftreaks of black and yellow, in the manner of the *Wafp*; and its antennæ are very beautifully feathered, and bearded like thofe of the males of many of the gnat-kind. The head is black, and the legs are yellowifh. The wings have a yellowifh caft, and near their end have each a large fpot of brown. The body of the female of this fpecies is always much thicker than that of the male; and the fexes are eafily diftinguifhed by this. *Reaumur*'s Hift. Inf. vol. 9. p. 19.

WASTE-*Cloths*, in a fhip of war, the cloths hung up on the uppermoft work of a fhip's hull, to fhade the men from an enemy in the fight; and therefore by fome are called *fights*.

WASTE-*Trees*, in a fhip, are thofe timbers which lie in her *Wafte*.

WASTORS, in our ftatutes, a kind of thieves fo called, and mentioned among robbers, draw-latches, &c. Stat. 4. c. 27. *Blount*, *Cowel*.

WATCH (*Cycl.*)—The movement of thefe machines will be ftopped with great cold; and therefore in very cold climates, it is proper to keep them in one's fob by day, and in the bed by night. See Phil. Tranf. N°. 465. Sect. 2.

WATCH-*Glafs*. Mr. Boyle informs us, that to fafhion glaffes for *Watches*, or the like purpofe, into a convex or concave figure,

figure, there is no neceffity for grinding: For, a fmooth and flat piece of glafs, of a competent thicknefs, being carefully laid upon a fhallow concave cylinder of iron, fo that the edges of both touch, the heat of a fire, warily applied, will foften the glafs, and fuffer it to fink into the form required. See Works abr. vol. I. p. 135.

WATCH-*Glafs*, aboard a fhip, runs four hours, and is ufed to fhift or change their *Watches* by. There are alfo *half-watches*, *hour-glaffes*, *minute*, and *half-minute-glaffes*; by which laft they count the knots when they heave the log, in order to find the fhip's way.

WATER, (*Cycl.*) in natural hiftory. See the Appendix.

WATER-*Bomb*, a name given by our chemift Godfrey to a machine he invented on the plan of Greyl's difcovery, for the extinguifhing accidental fires in houfes. He confidered firft, that the unmanageable fize of Greyl's engine was a very great objection; and on this plan contrived a medicated liquor, which was fuch an enemy to fire, that a very fmall quantity would extinguifh as much as a greatly larger of common water; and this liquor had the farther advantage, that it might be kept ever fo long without corrupting, and by that means the veffels containing it would remain always fit for ufe; whereas in Greyl's method they muft have been rotted by the corrupting and fermenting of the water, after a few years.

The author of this invention tried it twice in public with us, and both times with all the fuccefs that could be wifhed: but the ftructure of the veffel was fo much the fame with that of Greyl's, that Godfrey cannot be allowed any farther merit, as an inventor, than that of contriving the medicated liquor inftead of common water. The machine is a wooden veffel, made very firm and ftrong, that the liquor, when once put in, cannot leak out any where; in the center of this is an oblong cylindric veffel, which is filled with gun-powder; a tube is brought from this to the head of the barrel, and this being filled with combuftible matter, and the inner cafe with powder, and both made of plate-iron, that no water may get in, the veffel is then filled with the medicated liquor. The top of the tube is then covered, and the thing fet by for ufe.

When there is occafion for it, it is only neceffary to uncover the tube, and fetting fire to the matter in it, it is conveyed to the veffel containing the powder, and the whole machine being thrown into the place where the fire is, is torn to pieces by the explofion, and the extinguifhing liquor fcattered every way about, on which the fire is quenched in an inftant.

The contriver of thefe things propofed the making three kinds of them, the one containing five gallons of the liquor; this was the largeft fize, and contrived for the largeft rooms, and moft urgent neceffities. The fecond kind contained three gallons; and the fmalleft, which was meant for a clofet, or other little room, contained only two gallons. The fmaller kind alfo had fometimes a peculiar difference in their ftructure, the powder-veffel being placed not in the center, but at the bottom: the intent of this was to fit them for chimneys, when on fire, as by this means the liquor, not being wanted to be fcattered on all fides, was carried moftly upwards. Thefe were fixed on the end of a long pole, and by this means thruft to a proper height up the chimney; and the tube that communicated the fire was placed downward.

The manner of ufing the machines for rooms on fire, is this: the perfon who has the care of them is to throw them as nearly as may be into the middle of the room, and then to retire to a little diftance: As foon as he hears the explofion, he may fafely enter the room, and with a cloth, or any thing of that kind, put out any remaining fparks of fire that there may be in particular places. If the room be fo large that one of the machines cannot difperfe the liquor to every part of it, two are to be ufed, one being laid at each end; and if feveral rooms are on fire at once, as many of the machines are to be ufed, one being thrown into each room. If a whole houfe is on fire, the lower rooms are firft to be taken care of, and after thefe the upper, as they afcend. Our Godfrey had fcarce better fuccefs than his predeceffor Greyl; for while he was making his public experiments, one Povey, collecting fome of the fragments of his broken veffels, found out the ingredient ufed in the medicated liquor, and made and fold the things in the fame place where he had proved his right to them. It is probable that the medicated liquor was no other than common water, with a large quantity of fal armoniac, that falt having this virtue of extinguifhing fire in a very remarkable degree; But it is greatly to be wondered at, that while all the world were convinced by experiments of the ufe of the machine, the author made but little advantage of it, and it is now difufed. Act. Erudit. Ann. 1724. p. 183.

WATER-*Dog*. The fportfmen generally efteem the black *Water*-fpaniels above thofe of any other colour, they being generally the moft hardy. If there be any farther judgment to be made from the colour, it is, that the fpotted or pied are generally the quickeft at fcent, and the fimple liver-coloured the quickeft at fwimming. Thefe, however, are but very uncertain rules to judge by, and the things principally to be regarded are the dogs being of a good breed, and well taught. As to the fhape, the head of a good *Water*-dog is generally round, and the hair curling, the ears large and broad, and hanging down; the eyes full and lively, the nofe fhort, and the lips like a hound's. The neck fhould be thick and fhort, the fhoulders broad, the legs ftrait, and the chine fquare. The buttocks fhould be round, and the thighs brawney. The pafterns ftrong, and the fore-feet round. The hair in general fhould be long and curled, not loofe and fhaggy.

As to the training up a dog for fporting, the mafter of him cannot begin when he is too young, the principal thing to be taught being obedience, and that being beft taught while the creature is young. As foon as he can lap, he fhould be taught to couch and lie clofe at command, and not to dare to ftir from that pofture till he is ordered; he will foon be brought to this by beating when he difobeys, and encouraging him when he does right. He fhould always be taught before the times of his eating, and never have his food given him, but when he has done fomething to deferve it. This will teach him always to do well, for the fake of the expected victuals. No perfon fhould ever interfere in the teaching, for two mafters breed a confufion, and the creature never will learn well from them.

The teacher muft be careful always to ufe the fame words in his leffons; thofe words are to be chofen which are the moft plain in their founds, and the moft diftinct from one another; and when thefe are once fixed upon, they muft never be altered; for the dog, being guided wholly by the found, not at all by the fenfe, any alteration of them, though the change be into words of the fame fenfe, quite confounds the creature. The word *down* is fhort and expreffive, and no other need be ufed when he is ordered to couch; but this being once given him, is never to be varied afterwards. The next found he fhould be taught after this, is the word of correction, for no leffon can be given but faults will be committed, and no fault fhould pafs without correction or blame; in this cafe the word *firrah*, fpoke angrily, will always be underftood: This, at firft, fhould be ufed with a lafh or a blow, and after a time he will know it as a word of difpleafure, and it will do for fmall faults without the blow. Certain words of cherifhing and encouragement muft alfo be taught him at the fame time, as *good boy*, or the like, ufing always with them actions and looks of chearfulnefs and pleafure, as clapping him on the back, and the like. After thefe, he muft be taught the meaning of fome words of advice, to put him in mind of his bufinefs, when he is out upon the fport, fuch as *take heed*, or the like. Thefe will not only fet him upon the watch, and make him diligent; but he will alfo be careful and cunning, and at the fame time chearful and pleafed in himfelf, at knowing that he is doing his mafter a pleafure.

When the young dog is thus far inftructed, and knows the meaning of the words of inftruction, correction, encouragement, and advice, and will couch and lie down at his mafter's feet, how and when he pleafes, and that with the fignal of a word, or a look only; he is then to be taught to follow clofe at his mafter's heels, by leading him by a line tied to his collar; he is to be carefully taught this, fo that when taken out to the fport, he muft neither run under the legs, nor hang too far back; this alfo will tend to the making him the more obedient. When he has been thus taught to follow with a line, he muft be taught to follow in the fame manner, loofe, and without a line, and always to be at his mafter's heels.

The next leffon he is to be taught, is to fetch and carry any thing he is commanded; this muft be taught him by way of fport, as a diverfion, by fhaking a glove at his head, and teaching him to fnatch it, and afterwards to catch it when thrown from the hand, and bring it back again; this he is to be encouraged in with cherifhing words, and all other means.

The beft method of perfecting the creature in this, is by letting him have no food, but what he earns by doing well, always feeding him when he does as he fhould do. If he carry the glove away, or play wantonly with it, and refufe to bring it back, his mafter is to ufe the word of inftruction, as *take heed*: If this does not bring him to, he is to ufe the word of correction; and if he does not bring it back at this, he muft proceed to blows; and on many other trials he muft have nothing given him to eat, till he has done as he ought, and has it by way of reward. When by this means he is taught fo well, that he will bring back the glove, wherever it is thrown, and carry it only to his mafter, though he is in company with other perfons, who all call him, he is then to be cherifhed and encouraged, and taught to bring back any thing elfe that is thrown, whether fticks, ftones, or any thing whatever. After this, he is to be taught to carry dead fowl, and finally live ones, and this with fo tender a mouth, as not to hurt them: thus he will be taught at length to bring the fowl that his mafter fhoots, without tearing them or hurting a feather.

The next leffon is to be taught by taking him out in the field, and dropping fomething unknown to him; after he is come to fome diftance from the place, he is to be fent back to feek for it, and if he bring it back, he is to be encouraged. If he bring back a wrong thing, he is to be encouraged for the attempt, and fent back again: By repeating this at different diftances

diftances, he will be taught to go back ever fo far in fearch of any thing; and if he fails in the leffons, he is to be chid, beaten, or kept fafting, for it, according to the offence.

When he has been perfected in all thefe leffons, he muft be taught his bufinefs of hunting; he is to be firft taught with tame fowl, which his mafter is to affift him in taking, and reward and encourage him when he has done. After this, he is to be fent in without affiftance to take the fowl alone, and if he fucceeds, he is to be encouraged and rewarded, and corrected if he fails. By this practice he will foon become mafter of his game; but great care is to be taken in the teaching him, when he has caught it, to bring it back to the fhore, without biting or hurting it.

The next thing to this, is the training him to the gun; to this purpofe he muft be taught to follow ftep by ftep behind his mafter, and under covert of his fhadow, till he has fhot, or, when there is occafion, to couch and lie clofe, never daring to ftir till the gun has gone off; and then, upon the leaft notice or beckoning, to come and do what he is commanded.

Many of thefe dogs are fo expert, that they will have their eye upon the game as foon as their mafter, and the moment the gun is gone off, they will, without bidding, go and fetch it; but this is being too forward, and if he is ufed afterwards with nets or lime-twigs, he will do great mifchief, by rufhing on the birds as foon as they are taken, and tearing the nets, or fpoiling the twigs. Obedience is the beft quality in this fort of dog, and it is better he fhould wait for command, than know his bufinefs without it.

The fportfmen, who know the time of birds moulting, make a very great ufe of this fort of dog, taking him with them without gun, net, or any other affiftance. The common moulting-time of *Water*-fowl is from June to Auguft; in this time they are not able to fly well, and in fome part of it, when their old wing-feathers are off, and the new ones are grown fcarce at all, the dog is then to be taken to the fides of rivers, and other waters, and fet to hunt about the clofe places, among which they hide themfelves at this time; the dog, being fet to hunt, will eafily find them in thefe retreats, and will take them either by leaping fuddenly upon them, or fairly purfuing fuch of them as have not the ufe of their wings.

There is alfo another great ufe of the dog in driving them without catching them. This is practifed only in moorifh and fenny countries, where they are very numerous. In thefe countries a proper place is to be fought for, where the birds retire to, and thefe are planted with nets; then the dog is fent into the *Waters* and places of covert, where they are fuppofed to be, and this at the moulting-time, when they cannot fly away from him. The alarm he puts them into which he firft attacks, foon calls many others together, and there is a large body of them formed, which the dog drives before him like a flock of fheep, and being directed by the fportfmen, frightens directly into the places of their retreat, where the nets are placed before-hand to receive them.

WATER-*Fowl.* We are apt to fuppofe that thefe birds have fomething more peculiar in their ftructure than they really have, to enable them to live without the benefit of refpiration a confiderable time. It was fuppofed that they could fubfift without air a long time, till Mr. Boyle found by his experiments with the air pump, that they could not bear the exhaufted receiver any longer than other birds, a full grown duck being killed in two minutes in it. But what is more obfervable is, that their power of remaining under *Water* is for a much more limited time than is imagined. On tying a weight to the legs of a duck, and finking her in a tub of water, it was found that two minutes immerfion proved very troublefome to her, and occafioned great efforts for rifing; that after this the air-bubbles were difcharged in plenty from the mouth and noftrils, and finally the beak was wide opened, the *Water* admitted, and the creature abfolutely drowned, fo as to be irrecoverably dead in fix minutes. A young duckling put into the *Water* in the fame manner, died at the end of the fourth minute, after difcharging many air-bubbles both from the noftrils and mouth, and yet more from the upper part of the head, a little behind the eyes. Phil. Tranf. N°. 62.

Water-fowl may be taken in great abundance by nets properly managed. The net for this purpofe fhould be always made of the fmalleft and ftrongeft packthread that can be got. The mefhes may be large, but the nets fhould be lined on both fides with other fmaller nets, every mefh of which is to be about an inch and half fquare each way, that as the fowl ftrike either through them or againft them, the fmaller may pafs through the great mefhes, and fo ftreighten and entangle the fowl.

Thefe nets are to be pitched for every evening flight of fowl, about an hour before fun-fet, ftaking them on each fide of the river, about half a foot within the water, the lower fide of the net being fo plummed, that it may fink fo far and no farther; place the upper fide of the net flantwife, fhoaling againft the *Water*, but not touching it by near two foot; and let the ftrings which fupport this upper fide of the net be faftened to fmall yielding fticks fet in the bank; thefe, as the fowl ftrikes, will give the net liberty to play, and to entangle them. Several of thefe nets fhould be placed at once over different parts of the river, at about twelve-fcore fathom diftance one from another; and if any fowl come that way, the fportfman will have a fhare of them. It is a good method, when the nets are fet to go to places fufficiently diftant from them with a gun, to fright them toward the places where the nets are; and wherever any of the fowl are ftarted from, it may not be amifs to plant fome nets alfo there to take them as they return. The nets are to be left thus placed all night, and in the morning the fportfman is to go and fee what is caught; he fhould vifit the river firft, and take up what are caught there, and, frightening the reft away to the other places where his nets are, he is next to vifit them, and take what are there fecured.

WATER-*Gavel*, in our old writers, a rent paid for fifhing in, or other benefits received from, fome river. *Blount.*

WATER-*Salamander.* See the article SALAMANDRA.

High WATER is when the tide is at the higheft. See the article TIDE, *Cycl.*

Low WATER is when the tide is at the loweft.

WATERING, (*Cycl.*)—WATERING *of Horfes.* All the while that a perfon is on a journey, the horfe fhould always be fuffered to drink of the firft good water he comes to after feven o' clock in the morning in fummer, and after nine or ten in the winter. Moderately pure water is to be preferred, that being beft of all which is neither too clear and penetrating, nor muddy and ftinking.

Though it is the cuftom in England to run and gallop horfes after drinking, which we call *Watering*-courfes, and which we fuppofe brings them into wind, yet Sollyfel, and many other of the beft judges of horfes, tell us, that it is one of the worft and moft pernicious practices that we can be guilty of; there can no good accrue from it, and many horfes are rendered purfy by it.

While a horfe is drinking, the rider fhould draw up his head five or fix times, making him move a little between every draught. The rider need not be afraid of giving him water, with proper moderation, even in almoft any circumftances. If he be warm and fweat very much, yet if he is not quite out of breath, and there are four or five miles to ride, he will be better after drinking a little, than if he had drank none at all; only obferving, that if the horfe were very warm at his going into the water, his pace muft not be lefs than a moderate trot when he comes out, that he may not be chilled.

In the time of a journey the horfe ought to be fuffered to drink in this manner, of the waters that come in the way, as often as may be; for if the rider happens to bait when he is hot and fweaty, he muft not be fuffered to drink of a long time, as it would endanger his life; and if he has not been *watered* in this manner on the road, his exceffive thirft will often prevent his eating, and he will not be able to touch any fort of food of an hour or two, which is ufually more time than the rider can ftay, and yet without eating at baiting-times he will not have ftrength to go on. The giving him water on the road will, on the contrary, keep him ready for food whenever it is offered him, and the rider need ftay no longer than his own refrefhment requires, the horfe eating immediately, and being readily qualified to go on again.

If there be any fhallow water in the way, a little before the coming to the inn where the horfe is to reft all night, it is always proper to ride him in, and not only give him a little drink, but ride him about feveral times, not quite up to the belly; this will clean his legs, and prevent humours from falling down into them. If the horfe be very warm, and there has been no convenience of *Watering* him upon the road, the oats that are given him fhould be firft fteeped a while in ale; this will induce him to eat, though he could not have touched any that were wholly dry.

Many are of opinion, that horfes are fometimes fpoiled by giving them oats before their water; but Mr. Sollyfel affirms, that though it be not the cuftom to give oats till afterwards, yet it never does any harm to feed the horfe with them both before and after drinking; and that it is often proper and neceffary, efpecially when the horfe has been hard rid, and is warm.

WATRY *Sores*, in the manege, called in French *mauvaifes eaux*, are a fuppuration of ftinking and malignant humours, which iffue from the paftern and fetlock joints of a horfe, and that from the hinder rather than the fore-legs.

WAVE (*Cycl.*)—This motion of the fea-water depends greatly on the winds, and on the fituation of mountains, in regard to the fea; for the winds are driven back from thefe with great impetuofity; and in fome places this occafions a great and very irregular undulation, befide that which is produced by the immediate action of the winds on the furface of the water, in their own direct courfe.

Waves are to be confidered as of two kinds, and thefe may be diftinguifhed from one another by the names of natural and accidental *Waves*.

The natural *Waves* are thofe which are regularly proportioned in fize to the ftrength of the wind, whofe blowing gives origin to them. The accidental *Waves* are thofe occafioned by the wind's reacting upon itfelf by repercuffion from hills and mountains, or high fhores, and by the wafhing of the *Waves* themfelves, otherwife of the natural kind, againft rocks and fhoals;

ſhoals; all theſe caſes give the *Waves* an elevation, which they can never have in their natural ſtate.

The great Mr. Boyle has proved by numerous experiments, that the moſt violent wind never penetrates deeper than ſix foot into the water; and it ſhould ſeem a natural conſequence of this, that the water moved by it can only be elevated to the ſame height of ſix foot from the level of the ſurface in a calm; and this ſix feet of elevation being added to the ſix of excavation, in the part whence that water ſo elevated was raiſed, ſhould give twelve foot for the utmoſt elevation of a *Wave*. This is a calculation that does great honour to its author; for Count Marſigli meaſured carefully the elevations of the *Waves* near Provence, and found that, in a very violent tempeſt, they aroſe only to ſeven foot above the natural level of the ſea, and this additional foot in height he eaſily reſolved into the accidental ſhocks of the water againſt the bottom, which was, In the place he meaſured them in, not ſo deep as to be out of the way of affecting the *Waves*; and he allows that the addition of one ſixth of the height of a *Wave*, from ſuch a diſturbance from the bottom, is a very moderate alteration from what would have been its height in a deep ſea, and concludes, that Mr. Boyle's calculation holds perfectly right in deep ſeas, where the *Waves* are purely natural, and have no accidental cauſes to render them larger than their juſt proportion

In deep water, under the high ſhores of the ſame part of France, this author found the natural elevation of the *Waves* to be only five foot; but he found alſo that their breaking againſt rocks, and other accidents to which they were liable in this place, often raiſed them to eight foot high.

We are not to ſuppoſe, from this calculation, that no *Wave* of the ſea can riſe more than ſix foot above its natural level in open and deep water, for *Waves* immenſely higher than theſe are formed in violent tempeſts in the great ſeas. Theſe, however, are not to be accounted *Waves* in their natural ſtate, but they are ſingle *Waves* formed of many others; for in theſe wide plains of water, when one *Wave* is raiſed by the wind, and would elevate itſelf up to the exact height of ſix foot, and no more, the motion of the water is ſo great, and the ſucceſſion of *Waves* ſo quick, that, during the time this is riſing, it receives into it ſeveral other *Waves*, each of which would have been at the ſame height with itſelf; theſe run into the firſt *Wave* one after another, as it is riſing; by this means its riſe is continued much longer than it naturally would have been, and it becomes terribly great. A number of theſe complex *Waves* ariſing together, and being continued in a long ſucceſſion by the continuation of the ſtorm, make the *Waves* ſo dangerous to ſhips, which the ſailors in their phraſe call mountains high. *Marſigli*, Hiſt. Phyſ. de la Mer.

WAVE-*Offering*, among the Jews, a ſacrifice offered by agitation or *waving* towards the four cardinal points. See the article AGITATION.

WAVED, or WAVEY, (*Cycl.*) in heraldry, denotes that the firſt of the family in whoſe arms it ſtands, acquired his honours for ſea ſervices, and has this peculiar commemoration of it ordered in his arms. *Niſbet*'s Heraldry.

WAX (*Cycl.*)—Before it is poſſible to underſtand the accounts authors give of the manner in which the bee collects its *Wax* and honey, and forms the cells to depoſit the laſt fluid in, it is neceſſary to underſtand the true ſtructure, and know the ſeveral parts of this little creature.

The anterior part of the head of a bee is triangular, and ſomewhat flat; it goes tapering from the baſe to the extremity, and the reticular eyes are placed at the ſides; theſe are of an oval figure, one point or end being much larger than the other. The narrower end of each eye is on the lower part of the head, and reaches almoſt to the origin of the teeth; there is a large ſpace between the eyes, and this is full of little irregularities. The antennæ are placed at the two ſides of an eminence in this part, coming near the eyes; they are of no very ſingular ſtructure, but are compoſed of ſeveral joints, and ſeem of the nature of horn; they are ſo made that they may be eaſily folded in two, and they are always found to be ſo in dead bees. The head is not very thick, but appears ſomewhat broad; and at the upper part there are placed three ſmall ſhining eyes in a triangular ſituation, as is the caſe in many other of the winged inſects.

The bee has a trunk and teeth, and the ſituation of theſe, at the extremity of the head, has a great ſhare in giving that part a triangular figure. The teeth, when they are not in action, meet in a point at their extremities, and form an angle which projects out from the cruſtaceous lips. Theſe teeth are a very eſſential part of the creature, and are not only intended for the common purpoſes of eating, but ſerve alſo to the great purpoſes of erecting the works within the hive. Theſe teeth are properly a ſort of grinders, one of which has its origin on one ſide of the head, and the other at the ſame height on the other; they are ſmaller near their origin than in any other part, and thence grow larger to the extremity, where they are cut off obliquely in ſuch a manner, that when their two ends are applied one againſt the other, they make a ſort of angular pair of pincers, which are able to lay very faſt hold of any thing; they are not only capable of meeting in this manner, but they can, upon occaſion, croſs one over the other; and this is the poſition they are uſually found in when the bee is dead. The truncated ends of the teeth have each a ſemicircular cavity, ſurrounded with hairs; theſe meeting, when the teeth are cloſed, form a regular cavity, capable of receiving whatever is ground to pieces by the ſides of the teeth. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 357.

The head of the bee is faſtened by a ſhort, flexile, and fleſhy neck to the breaſt; the hinder part of the head receives the end of the neck, and near the inſertion of this is placed the origin of the trunk; this goes ſtrait forward from this place as far as the angle made by the teeth, and thence returns in a curved form to fall over the breaſt. On the ſides and upper part of the breaſt are the origin of the four wings, and on its under part the four legs are inſerted. There are alſo on the breaſt the four principal ſtigmata, which are ſituated as in other flies. In the ordinary poſition of the parts, the poſterior end of the corcelet is placed cloſely upon the firſt ring of the body, ſo that they ſeem joined together by their whole ſurfaces. But the true ſtate of theſe parts is, that they are only joined by a ligament; this ligament is placed on the lower part of the corcelet and body, and, being very ſhort, is often not at all ſeen. The poſterior part of the corcelet alſo has a convexity, and the anterior part of the firſt ring of the body a cavity that receives it; whence theſe parts, in their common ſtate, appear joined together in a great extent, in which they really only touch. The body is compoſed of ſix rings, which are covered with very ſtrong ſcales; theſe are very neceſſary to them, for they often fight, and were it not that there was ſuch a defence againſt one anothers ſtings, they would unqueſtionably often periſh.

The body of the bee appears in ſeveral places ſpotted with a reddiſh colour; all theſe parts are ſo many hairy ſpots, and owe their colour to the reddiſh hue of the hair. The body, breaſt, and head of the bee, are alſo covered in many places with longer and more diſtinguiſhable hairs. In examining the creature in this view, it is proper to uſe a microſcope, for tho' the naked eye ſhews many hairs, this inſtrument ſhews vaſt numbers more, and thoſe in places where they could not have been ſuſpected to grow; the very eyes are not exempt from them, the large reticulated ones being as thick ſet with ſhort and fine hairs, as almoſt any other part of the body.

Theſe hairs, when ſeen through the microſcope, do not appear in form of ſingle filaments, but they repreſent ſo many buſhes or beds of moſs, every filament, or as it appears to the naked eye, ſingle hair, being thus ſeen to be branched and beſet with ſhort prominences reſembling leaves of a plant. *Reaumur*'s Hiſt. Inſ. vol. 9. p. 361.

Many have ſuſpected what are called the reticulated eyes of flies not to be real eyes, and theſe growing hairs upon them has ſeemed a convincing proof of their not being ſo, ſince it has been ſuppoſed that they could ſerve to no other purpoſe than to impede viſion. Mr. Hook and others have ſaid a great many things in favour of the opinion of their being eyes; but Mr. Reaumur has proved it beyond all doubt; he choſe to this purpoſe the eyes of the bee for his experiment, as they were the moſt hairy of thoſe of any known inſect, and therefore the leaſt qualified to act as eyes, according to the common opinion. The bee is known to ſee very well; and this author determined to try whether ſhe would do ſo without the aſſiſtance of theſe reticulated ſubſtances; he to this purpoſe covered over the reticulated parts of the head of three or four bees of the common kind, and then incloſed them with twenty others in a wooden box. When they had been there ſome time, he opened the lid of the box; thoſe which were not varniſhed immediately flew out, and went directly to their hive; the others, whoſe eyes were thus cloſed up, continued in the box a long time, and when diſturbed, in order to ſend them out, flew in various directions againſt the ſides of the box; and in fine, when in the air, ſeemed to know nothing of their way to the hive, but flew up into the air till out of ſight.

This experiment ſeems to have wholly determined the point, ſince if the creature be rendered blind by the covering the reticulated ſubſtances on the head, it muſt be allowed that thoſe reticulated ſubſtances are the eyes. The hairs which grow on them do not take their origin from the pupils or lenſes, of which they are compoſed, but from the ſubſtance which ſeparates or makes cells for them; and though theſe hairs appear to ſome to be greatly injurious to viſion, it may very poſſibly be, that they ſerve only as our eye-laſhes, to break the too violent light to which the eyes are ſometimes expoſed. It is to be obſerved, that the hairs which grow upon the reticular eyes of the bee are not branched or foliated in the manner of thoſe of the body, but are only ſingle, ſhort, and ſtrait filaments, perfectly reſembling the hairs of large animals. When Mr. Reaumur had thus proved the uſe of the reticulated eyes of the bee, he was determined to try the uſe alſo of the three ſmall and ſhining eyes, which ſtand on a triangle on the back part of the head; to this purpoſe he covered theſe eyes with the ſame varniſh with which he had before covered the reticulated ones, but leaving theſe bare: he did this with ſeveral bees, and afterwards placing them at a few yards diſtance from the hive, he left them at liberty. Not one of them found the way to the hive, or ſeemed able to direct its flight towards it; but they all flew directly to the flowers that were

neareft them, to which they perfectly faw the way. Thefe did not fly upwards, as all the others did.

The hairs of the bee are of different ufe from that of the hairs of other animals, and therefore all this varied ftructure was neceffary. See the article HONEY.

The legs of the bee are fix; the two anterior pairs are of the fame length; but the two hinder legs, or pofterior pair, are confiderably longer than the others. Each leg is compofed of five principal pieces; of thefe, that next the origin is thicker and fhorter than any of the others. This is a fort of conic button, to the end of which the fecond piece is articulated; this is much longer and thicker in the middle, and thinner at each end; the third piece of the leg in the hinder pair is different from that of the others; it is flat and of a triangular figure, and is called by Reaumur and other French authors, *palette triangulaire*. This is articulated with the fecond piece by its point, and with the fourth by its broad part. This third piece in the fecond pair of legs is much lefs flat and triangular than in the hinder pair; and in the firft pair it is fcarce at all fo. The fourth piece in the two hinder pairs of legs is alfo broad and flat; but it is not triangular, but of a fquare figure. The French writers call this the *broffe*. This is much larger and broader on the hinder pair of legs than on the fecond, and in the firft it is not at all of this flatted or fquare figure, but is cylindric and flender. The fifth piece of each leg is what may be called the foot. It is an extremely fine part, and is compofed of five joints, placed clofe to one another. The four anterior pieces are a fort of truncated cones, a little flatted, and are joined by the bafe of the firft to the head of the fecond, and fo on. The laft piece is long, flender, and cylindric, and is terminated by two hooks refembling the claws of a bird. One of thefe is twice as long as the other, and between thefe two claws there is placed a flefhy protuberance covered with hairs, of the nature of that of the feet of the flies; by means of which they are able to climb upon glafs, or other fmooth bodies. *Reaumur's* Hift. Inf. vol. 9. p. 368.

The firft joint of all the legs of the bee is covered with the foliated hairs before-mentioned; the fecond piece has ftrait hairs, and the third piece, or palette on the hinder pair, is fo befet with large and ftiff hairs all round its edges, and fo hollowed in its anterior part near the bottom, that it refembles a fort of bafket, and it is made for that very purpofe, ferving the creature as a fort of bafket to carry home its *Wax* in.

The third joint of the firft and fecond pair of legs has no ftructure like this; and we find that it is not in thofe legs ufed to the fame purpofes, it being only on the laft pair of legs that the lumps of *Wax* are feen, when the bee is loaded with them. The fourth piece of the two hinder pair of legs, which the French call the *broffe*, or the brufh, and which is of a fquare figure, ferves the creature in the place of a brufh, and is in reality formed fomewhat like one. The outer furface of this is convex and fmooth, the inner is concave and hairy, and the hairs on this part do not ftand fingly, but are placed in little tufts, wider at the extremity than at their origin, and exactly refembling the tufts of hair in our clothes-brufhes. *Reaumur*, Hift. Inf. vol. 9. p. 369.

The feveral authors who have treated ever fo largely on the arts and induftry of bees, and defcribed the manner of forming their waxen ftructures or combs for the reception of their honey, have yet omitted to clear up the material point of what that *Wax* is, what it is originally compofed of, and by what artifice the bee works it out of its rough ftate, in the plant in which it is found, into the fubftance which we call *Wax*.

It is very certain that the farina fœcundans of the flowers of plants, contained in their apices, is the matter of which the bees form their *Wax*; they either diflodge this from its cells with their teeth, or elfe merely by rubbing their bodies among the ftamina and apices, load themfelves with the globules of it, which their hairs keep fticking upon their body, and which they afterwards brufh off with their legs, and, by degrees, collect into balls or lumps, which they depofit upon the flat and triangular piece, which makes the third joint of the hinder pair of their legs.

The lumps of *Wax* with which we fee them loaded in this part, and carrying to their hives, is only the farina of flowers worked up and compreffed into a mafs or fort of cake. The ftamina of the flowers therefore fuftain certain cafes, containing a powder, which is the matter of bees *Wax*. This powder, thus collected into lumps on the legs of the bees, is called rough *Wax*, and is probably *Wax* to all intents and purpofes, only wanting a little beating together. *Wax*, therefore, fo long efteemed an animal fubftance, will appear to be a native vegetable production. We know very well, that different fpecies of trees yield us the feveral gums and refins ufed in medicine and mechanics, in the fame perfect form in which we fee and ufe them; and there is a fpecies of fhrub, very well known in America, and called the *candle-berry-tree*, the berries of which yield a *Wax* perfect in all refpects, and fit for the making candles, *&c.* without having paffed through the manufacture of the bee at all.

In the fame manner it feems that all our common plants produce *Wax* in their flowers, but that this is in fuch very fmall quantities, that thefe little animals alone are able to collect and work it into a ftate fit for our ufe: but this does not abfolutely hold good; for if we examine what we call rough *Wax*, that is, the balls of *waxey* matter on the legs of the bees, we fhall find that it is not yet bees *Wax*. It is an eafy matter to catch a few bees as they return in a morning loaded to the hive, and on feparating the *waxey* matter from their legs, and preffing it between the thumb and a finger, it will be found to differ greatly from perfect *Wax*. This would, in a like cafe, foften of itfelf, and form a regular and uniform flat cake; whereas, on the contrary, the matter from the bees legs is friable, not ductile, will not foften itfelf between the fingers; and when preffed a little to a flatnefs, it is feen to be ftill compofed of regular globules, which all retain their priftine form, not mixing or blending among one another, and hanging together only by means of fome humidity which hangs about their furfaces. If it be tried by a greater warmth, it will be found in the fame manner to differ from *Wax*, in the want of fome of its effential qualities. If a piece of it be put into a filver fpoon, and held over lighted charcoal, it will not melt as *Wax* would do, but will take fire and burn regularly into a cinder: and finally, if it be carefully worked into a long thread, and the end of it put to the flame of a candle, it will take fire as readily as *Wax* would do, but it will not run or melt like it, but burn like a piece of dry wood. Water alfo gives as evident a proof of the difference between the rough *Wax* and the perfect, as fire. If a piece of this rough *Wax*, as taken from the legs of the bee, be thrown into water, it finks to the bottom; whereas perfect *Wax* will always fwim upon the top: This might feem owing to the great humidity of the rough *Wax*, while loaded with the juices of the plant; but it is proved by experiment that this is not the cafe; for if the rough *Wax* be kept till ever fo perfectly dry, it ftill preferves its own nature, and will fink in water as readily as at firft. *Reaumur's* Hift. Inf. vol. 10. p. 39.

From the whole then it is evident, that the bee does fomething to the matter of which *Wax* is made, in order to the reducing it into perfect *Wax*. It might be fuppofed that the feveral globules of this matter were fo many facks containing the true *Wax*; and that the bee need only break or open thofe facks, to get at the true and genuine *Wax* within; but this does not appear to be the cafe upon experiment, fince if this matter be ever fo nicely and carefully pounded and broke to pieces, it does not become any more *Wax* for this treatment, nor is any more fufible or ductile than before. The opinion of Swammerdam and Maraldi was, that the bee added fome other matter to the rough *Wax*, in order to reduce it to this proper ftate. And as there is no fubftance fo ready for the bee as honey, they fuppofed that fhe mixed honey with this matter, and fo made *Wax* of the compound; but experiment is alfo wholly againft this, fince if honey, and this matter collected from the bees, be mixed in any proportions, the compound has no more the properties of *Wax* than it had before, but ftill remains a quite different fubftance. Swammerdam afterwards fell into another opinion, in regard to the matter mixed with the rough *Wax*, in order to render it perfect; this was, that the bee mixed with it the venomous liquor, of which fhe has a bag full near the tail, in order to poifon the wounds made by her fting. He made fome experiments on this plan, which he thought favoured his fyftem, and endeavours to ftrengthen the probability, by obferving, that as the fting of a bee comes but very little into ufe, it would not have been neceffary that the creature fhould have been thus conftantly fupplied with a large bag of this matter, if nature had not allotted to it fome other ufe befide that regarding the fting. This opinion prevailed among the learned, till Mr. Reaumur of late proved by experiments, that this liquor had no effect on the matter found on the thighs of the bee, as to the turning it into *Wax*; and alfo, that feveral creatures which make no true genuine *Wax*, fuch as the humble-bee, the wafp, and the hornet, whofe combs are made of a fort of paper, yet have all this bag of liquor near their fting.

It is moft probable, that the method in which the bees turn the farina of flowers into *Wax*, is a very fimple one; and moft likely it confifts only in a fort of beating the quantities of them, which they collect, till they are very thoroughly united. We have never been able yet to difcover their manner of doing it; but this appears moft like the courfe of nature, in the operations of other infects; if this be the cafe, it would be poffible, perhaps, for us to imitate their method, and procure for ourfelves *Wax* out of the ftamina of flowers; this would be a difcovery of the utmoft importance: For though at prefent the bees which work it for us coft us nothing in keeping, yet it is to be obferved, that they are too few in number to collect fo much as we might wifh. Doubtlefs it is not one thoufandth part of the waxey matter, produced only by a few plants, that the bees of a whole province collect, while the reft all falls to the ground, and is loft. If we could arrive at the way of converting the farina of flowers into *Wax*, without the affiftance of the bee, we might have it in infinitely larger quantities; fince children might be taught to beat off, or fhake down, the farina from numbers of plants, which, when in full flower, would yield a much greater quantity than could be expected by thofe who are not converfant in thefe ftudies.

The

The probability of succefs in an attempt of this kind, has engaged the French naturalifts in the following trials.

Mr. Geoffroy, in his account of the farina of plants, obferves, that they preferve their figure a long time when immerfed in feveral liquors, but that they impart a tincture to thofe liquors. This induced Mr. Reaumur, to try the experiment of what different fluids were able to extract from them. For this purpofe he collected a confiderable quantity of the rough matter from the legs of the bees of one of his hives, and dividing it into three parts, he poured upon one fome common water, upon the other fpirit of wine, and upon the third oil of turpentine.

When thefe had all ftood three months, often renewing the liquors, he evaporated the water, which was coloured of a deep and dufky brown, to a perfect drynefs. When this was done, there remained at the bottom of the fpoon in which the evaporation was made, a fmall quantity of a perfect gum, which had all the properties of the common vegetable gums, and was as eafily foluble in water as any other of them.

The impregnated fpirit of turpentine was next evaporated; but the refiduum was not great in quantity, and was in fo much owing to the liquor itfelf, that little could be judged from it. In trials made after this, by boiling the rough *Wax* in frefh oil of turpentine, this appeared to be but a very poor menftruum for it, the *Wax* rather hardening than foftening in it.
